|-------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|----------|
| 31:11 | RESERVED | Reserved | R | 0x000000 |
| 10 | RWE | Remote wake-up enable This bit is used to enable or disable the remote wakeup feature upon detection of upstream resume signaling. | RW | 0 |
| 9 | RWC | Remote wake-up connected. This bit indicates whether the host controller supports remote wakeup signaling. | RW | 0 |
| 8 | IR | Interrupt routing This bit determines the routing of interrupts generated by events registered in HCINTERRUPTSTATUS . 0x0: All interrupts are routed to the normal host bus interrupt mechanism.. 0x1: Interrupts are routed to the system management Interrupt. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 7:6 | HCFS | Host controller functional state 0x0: HCFS: USB reset 0x1: HCFS: USB resume 0x2: HCFS: USB operational 0x3: HCFS: USB suspend | RW | 0x0 |
| 5 | BLE | Bulk list processing enable 0x0: Bulk ED list is not processed after the next SOF. 0x1: Enables processing of bulk ED list in the next frame. | RW | 0 |
| 4 | CLE | Control list processing enable 0x0: Control ED list is not processed after the next SOF. 0x1: Enables processing of control ED list in the next frame. | RW | 0 |
| 3 | IE | Isochronous ED processing enabled by host controller driver 0x0: Isochronous EDs are not processed. 0x1: Enables processing of isochronous EDs | RW | 0 |
| 2 | PLE | Periodic list enable 0x0: Periodic ED lists are not processed after the next frame. 0x1: Enables processing of periodic ED lists in the next frame. | RW | 0 |
| 1:0 | CBSR | Control/bulk service ratio. Specifies the ratio between control and bulk EDs processed in a frame. 0x0: One control ED per bulk ED 0x1: Two control ED per bulk ED 0x2: Three control ED per bulk ED 0x3: Four control ED per bulk ED | RW | 0x0 |

|-------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:18 | RESERVED | Reserved | R | 0x0000 |
| 17:16 | SOC | Scheduling overrun count This is used to monitor any persistent scheduling problems. These bits are incremented on each scheduling overrun error. It is initialized to 0x0 and wraps around at 0x3. | R | 0x0 |
| 15:4 | RESERVED | Reserved | R | 0x000 |
| 3 | OCR | Ownership change request. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| | | This bit is set to request a change of control of the host controller. | | |
| 2 | BLF | Bulk list filled This bit is used to indicate whether there are any TDs on the bulk list. It is set whenever it adds a TD to an ED in the bulk list. | RW | 0 |
| 1 | CLF | Control list filled This bit is used to indicate whether there are any TDs on the control list. It is set whenever it adds a TD to an ED in the control list. | RW | 0 |
| 0 | HCR | Host controller reset (software reset). Set this bit to initiate a USB host controller reset. This resets most USB host controller OHCI registers. OHCI register accesses must not be attempted until a read of this register returns a 0. 0x0: No effect 0x1: USB host controller is reset. | RW | 0 |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----|----|----|----|----|----|----|----|-------|----|----|----|----|----|----|----|----------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| FIT | | | | | | | | FSMPS | | | | | | | | RESERVED | | | | FI | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31 | FIT | Frame interval toggle This bit is toggled whenever it loads a new value to FI. | RW | 0 |
| 30:16 | FSMPS | Largest data packet size for full-speed packets, bit times This field specifies a value which is loaded into the largest data packet counter at the beginning of each frame. | RW | 0x0000 |
| 15:14 | RESERVED | Reserved | R | 0x0 |
| 13:0 | FI | Frame interval. Number of 12-MHz clocks in the USB frame. The nominal value is set to 11,999, to give a 1-ms frame. | RW | 0x2EDF |

If current connect status is 0, sets instead connect status change to inform the USB host controller driver of an attempt to suspend a disconnected port. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 1 | PES_SPE | Port 2 port enable status/set port enable. This bit is automatically set at completion of port 2 USB reset if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend if the port was not enabled when the USB resume completed. Read 0x0: Port 2 is not enabled. Read 0x1: Port 2 is enabled. Write 0x0: No effect Write 0x1: When port 2 current connect status is 1 sets the port 2 port enable status bit. When port 2 current status is 0 has no effect. | RW | 0 |
| 0 | CCS_CPE | Port 2 current connection status/clear port enable Read 0x0: No USB device is attached to port 2. Read 0x1: A USB device is currently attached to port 2. Write 0x0: No effect Write 0x1: Clears the port 2 port enable bit Note: This bit is set to 1 if the HCRHDESCRIPTORB[1] DR bit is set to indicate a nonremovable device on port 2. | RW | 0 |

CAUTION

The high-speed USB registers are limited to 32-bit data accesses; 16-bit and 8-bit accesses are not allowed and can corrupt register content.

EHCI register descriptions conform to the EHCI USB standard: *Enhanced Host Controller Interface (EHCI) Specification for USB, Release 1.1*. For more information about these registers or for new specification releases, search EHCI on www.usb.org.

23.11.6.6.2 EHCI Register Description

Table 23-1132 through Table 23-1174 describe the EHCI registers.

| 31:20 | RESERVED | Reserved | R | 0x000 |
| 19:17 | RESERVED | Reserved | R | 0x0 |
| 16 | P_INDICATOR | Port indicator support indication This bit indicates whether the ports support port indicator control. 0x1: The port status and control registers include a read/write field for controlling the state of the port indicator. | R | 0 |
| 15:12 | N_CC | Number of companion controllers This field indicates the number of companion controllers associated with this USB 2.0 host controller. 0x0: There are no companion host controllers. Port-ownership hand-off is not supported. Only high-speed devices are supported on the host controller root ports. Others: There are companion USB 1.1 host controller(s). Port-ownership hand-off is supported. High-, full-, and low-speed devices are supported on the host controller root ports. | R | 0x1 |
| 11:8 | N_PCC | Number of ports per companion controller This field indicates the number of ports supported per companion host controller. It is used to indicate the port routing configuration to system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2, then N_PCC can have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. The number in this field must be consistent with N_PORTS and N_CC. | R | 0x3 |
| 7 | PRR | Port routing rules The first N_PCC ports are routed to the lowest-numbered function companion host controller, the next N_PCC ports are routed to the next lowest-function companion controller, and so on. | R | 0 |
| 6:5 | RESERVED | Reserved | R | 0x0 |
| 4 | PPC | Port power control This field indicates whether the host controller implementation includes port power control. 0x0: The ports do not have port power switches. 0x1: The ports have port power switches. | R | 1 |
| 3:0 | N_PORTS | Number of downstream ports This field specifies the number of physical downstream ports implemented on this host controller. | R | 0x3 |

| 16 | RESERVED | Reserved | R | 0 |
| 15:8 | EECP | EHCI extended capabilities pointer This field indicates the existence of a capabilities list. 0x0: No extended capabilities are implemented. Others: The offset in PCI configuration space of the first EHCI extended capability. | R | 0x00 |
| 7:4 | IST | Isochronous scheduling threshold This field indicates where software can reliably update the isochronous schedule in relation to the current position of the executing host controller. The host controller can hold one microframe of isochronous data structures before flushing the state. | R | 0x1 |
| 3 | RESERVED | Reserved | R | 0 |
| 2 | ASPC | Asynchronous schedule park capability 0x1: The host controller supports the park feature for high-speed queue heads in the asynchronous schedule. The feature can be disabled or enabled and set to a specific level by using the USBHOST.USBCMD[11]ASPME bit and the USBHOST.USBCMD[9:8] ASPMC bit field. | R | 1 |
| 1 | PFLF | Programmable frame list flag 0x0: System software must use a frame list length of 1024 elements with this host controller. 0x1: System software can specify and use a smaller frame list and configure the host controller through the USBHOST.USBCMD[3:2] FLS bit field. The frame list must always be aligned on a 4-K page boundary. | R | 1 |
| 0 | BIT64AC | 64-bit addressing capability This field documents the addressing range capability of this implementation. 0x0: Data structures using 32-bit address memory pointers 0x1: Data structures using 64-bit address memory pointers | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:28 | RESERVED | Reserved | R | 0x0 |
| 27:24 | HIRD | Host-initiated resume duration. If LPM is enabled, this field is RW; otherwise, it is R. The minimum for K-state during resume from LPM: 0x0: 50 μ s Each increment adds 75 μ s. | RW | 0x0 |
| 23:16 | ITC | Interrupt threshold control This field is used by the system software to select the maximum rate at which the host controller issues interrupts. The only valid values are defined below. If software writes an invalid value to this register, the results are undefined. 0x00: Reserved 0x01: 1 microframe 0x02: 2 microframes 0x04: 4 microframes 0x08: 8 microframes (default, equates to 1 ms) 0x10: 16 microframes (2 ms) 0x20: 32 microframes (4 ms) 0x40: 64 microframes (8 ms) Others: Undefined | RW | 0x08 |
| 15:12 | RESERVED | Reserved | R | 0x0 |
| 11 | ASPME | Asynchronous schedule park mode enable 0x0: Park mode is disabled. 0x1: Park mode is enabled. | RW | 1 |
| 10 | RESERVED | Reserved | R | 0 |
| 9:8 | ASPMC | Asynchronous schedule park mode count It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the asynchronous schedule before continuing traversal of the asynchronous schedule. Valid values are 0x1 to 0x3. Software must not write 0 to this bit when park mode enable is 1 because this may result in undefined behavior. | RW | 0x3 |
| 7 | LHCR | Light host controller reset It allows the driver to reset the EHCI controller without affecting the state of the ports or the relationship to the companion host controllers. Read 0x0: Light host controller reset is complete and it is safe for host software to reinitialize the host controller. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| | | Read 0x1: Light host controller reset is still ongoing. | | |
| 6 | IAAD | Interrupt on async advance doorbell This bit is used as a doorbell by software to tell the host controller to issue an interrupt the next time it advances asynchronous schedule. Write 0x1: Ring the doorbell. Software must not write 1 to this bit when the asynchronous schedule is disabled. Doing so may yield undefined results. | RW | 0 |
| 5 | ASE | Asynchronous schedule enable This bit controls whether the host controller skips processing the asynchronous schedule. 0x0: Do not process the asynchronous schedule 0x1: Use the USBHOST.ASYNCLISTADDR register to access the asynchronous schedule. | RW | 0 |
| 4 | PSE | Periodic schedule enable This bit controls whether the host controller skips processing the periodic schedule. 0x0: Do not process the periodic schedule 0x1: Use the USBHOST.PERIODICLISTBASE register to access the periodic schedule. | RW | 0 |
| 3:2 | FLS | Frame list size This field specifies the size of the frame list. The size of the frame list controls which bits in the frame index register should be used for the frame list current index. 0x0: 1024 elements (4096 bytes) 0x1: 512 elements (2048 bytes) 0x2: 256 elements (1024 bytes), for resource-constrained environments 0x3: Reserved | RW | 0 |
| 1 | HCR | Host controller reset This control bit is used by software to reset the host controller. Write 0x1: Reset the host controller, the PCI configuration registers are not affected by this reset and all operational registers are set to their initial values. This bit is set to 0 by the host controller when the reset process is complete. | W | 0 |
| 0 | RS | Run/stop 0x1: Run, the host controller proceeds with execution of the schedule. The host controller continues execution as long as this bit is set to 1. 0x0: Stop, the host controller completes the current and any actively pipelined transactions on the USB and then halts. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:16 | RESERVED | Reserved | R | 0x0000 |
| 15 | ASS | Asynchronous schedule status The bit reports the current real status of the asynchronous schedule. 0x0: The status of the asynchronous schedule is disabled. 0x1: The status of the asynchronous schedule is enabled. | R | 0 |
| 14 | PSS | Periodic schedule status The bit reports the current real status of the periodic schedule. 0x0: The status of the periodic schedule is disabled. 0x1: The status of the periodic schedule is enabled. | R | 0 |
| 13 | REC | Reclamation It is used to detect an empty asynchronous schedule. | R | 0 |
| 12 | HCH | Host controller halted This bit is a 0 whenever the USBHOST.USBCMD[0] RS bit is a 1. The host controller sets this bit to 1 after it has stopped executing as a result of the RS bit being set to 0, either by software or by the host controller hardware. | R | 1 |
| 11:6 | RESERVED | Reserved | R | 0x00 |
| 5 | IAA | Interrupt on async advance System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by setting the USBHOST.USBCMD[6] IAAD bit to 1. This status bit indicates the assertion of that interrupt source. | RW | 0 |
| 4 | HSE | Host system error The host controller sets this bit to 1 when a serious error occurs during a host system access involving the host controller module. | RW | 0 |
| 3 | FLR | Frame list rollover The host controller sets this bit to 1 when the USBHOST.FRINDEX rolls over from its maximum value to 0. The exact value at which the rollover occurs depends on the frame list size. | RW | 0 |
| 2 | PCD | Port change detect The host controller sets this bit to 1 when any port for which the USBHOST.PORTSC_ <i>i</i> [13] PO bit is set to 0 has a change bit transition from 0 to 1 or a USBHOST.PORTSC_ <i>i</i> [6] FPR bit transition from 0 to 1. This bit is also set as a result of the USBHOST.PORTSC_ <i>i</i> [1] CSC bit being set to 1 after system software has relinquished ownership of a connected port by setting the USBHOST.PORTSC_ <i>i</i> [13] PO bit to 1. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 1 | USBEI | USB error interrupt The host controller sets this bit to 1 when completion of a USB transaction results in an error condition. | RW | 0 |
| 0 | USBI | USB interrupt The host controller sets this bit to 1 on completion of a USB transaction, which results in the retirement of a transfer descriptor that had its IOC bit set. The host controller also sets this bit to 1 when a short packet is detected (actual number of bytes received was less than the expected number of bytes). | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:25 | DEVICEADDRESS | The USB device address for the device attached to and immediately downstream from the associated root port. R/W only if LPM is enabled; otherwise, R. | RW | 0x00 |
| 24:23 | SUSPENDSTATUS | Addition for LPM support. Indicates status of L1 suspend request: 0x0: Success 0x1: Not yet 0x2: Not supported 0x3: Time-out/error | R | 0x0 |
| 22 | RESERVED | Reserved | R | 0 |
| 21 | WDE | Wake on disconnect enable This field is 0 if the PP bit is 0. Write 0x1: Enables the port to be sensitive to device disconnects as wake-up events. | RW | 0 |
| 20 | WCE | Wake on connect enable This field is 0 if the PP bit is 0. Write 0x1: Enables the port to be sensitive to device connects as wake-up events. | RW | 0 |
| 19:16 | PTC | Port test control The port is operating in specific test modes as indicated by the specific value. The encoding of the test mode bits are: 0x0: Test mode not enabled | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset | | | | | | | | | | | | | | | |
|-------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-----------|----------------|-----|-----|-------------------------------------------|-----|---------|---------------------------------------------------------------------------------------------|-----|---------|-------------------------------------------------------------------------------|-----|-----------|------------------------------------------------------------------------------|----|-----|
| | | 0x1: Test J_STATE 0x2: Test K_STATE 0x3: Test SE0_NAK 0x4: Test Packet 0x5: Test FORCE_ENABLE Others: Reserved | | | | | | | | | | | | | | | | | |
| 15:14 | PIC | Port indicator control (not implemented) | R | 0x0 | | | | | | | | | | | | | | | |
| 13 | PO | Port owner This bit unconditionally goes to 0x0 when the USBHOST.CONFIGFLAG[0] CF bit makes a transition from 0 to 1. This bit unconditionally goes to 0 whenever the USBHOST.CONFIGFLAG[0] CF bit is 0. 0x1: A companion host controller owns and controls the port. | RW | 1 | | | | | | | | | | | | | | | |
| 12 | PP | Port power The function of this bit depends on the value of the USBHOST.HCSPARAMS[4] PPC bit. The behavior is as follows: <table border="1"> <thead> <tr> <th>PPC</th> <th>PP</th> <th>Operation</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>0x0</td> <td>Forbidden</td> </tr> <tr> <td>0x0</td> <td>0x1</td> <td>Host controller does not have port power control switches. Each port is hardwired to power.</td> </tr> <tr> <td>0x1</td> <td>0x0</td> <td>Host controller has port power control switches. Current switch state is off.</td> </tr> <tr> <td>0x1</td> <td>0x1</td> <td>Host controller has port power control switches. Current switch state is on.</td> </tr> </tbody> </table> When an overcurrent condition is detected on a powered port and the USBHOST.HCSPARAMS[4] PPC bit is a 1, the PP bit in each affected port may be transitioned by the host controller from 1 to 0. | PPC | PP | Operation | 0x0 | 0x0 | Forbidden | 0x0 | 0x1 | Host controller does not have port power control switches. Each port is hardwired to power. | 0x1 | 0x0 | Host controller has port power control switches. Current switch state is off. | 0x1 | 0x1 | Host controller has port power control switches. Current switch state is on. | RW | 0 |
| PPC | PP | Operation | | | | | | | | | | | | | | | | | |
| 0x0 | 0x0 | Forbidden | | | | | | | | | | | | | | | | | |
| 0x0 | 0x1 | Host controller does not have port power control switches. Each port is hardwired to power. | | | | | | | | | | | | | | | | | |
| 0x1 | 0x0 | Host controller has port power control switches. Current switch state is off. | | | | | | | | | | | | | | | | | |
| 0x1 | 0x1 | Host controller has port power control switches. Current switch state is on. | | | | | | | | | | | | | | | | | |
| 11:10 | LS | Line status These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. This field is valid only when the port enable bit is 0 and the current connect status bit is set to 1. The encoding of the bits is: <table border="1"> <thead> <tr> <th>Bits[11:10]</th> <th>USB State</th> <th>Interpretation</th> </tr> </thead> <tbody> <tr> <td>0x0</td> <td>SE0</td> <td>Not low-speed device, perform EHCI reset.</td> </tr> <tr> <td>0x2</td> <td>J-state</td> <td>Not low-speed device, perform EHCI reset.</td> </tr> <tr> <td>0x1</td> <td>K-state</td> <td>Low-speed device, release ownership of port.</td> </tr> <tr> <td>0x3</td> <td>Undefined</td> <td>Not low-speed device, perform EHCI reset.</td> </tr> </tbody> </table> | Bits[11:10] | USB State | Interpretation | 0x0 | SE0 | Not low-speed device, perform EHCI reset. | 0x2 | J-state | Not low-speed device, perform EHCI reset. | 0x1 | K-state | Low-speed device, release ownership of port. | 0x3 | Undefined | Not low-speed device, perform EHCI reset. | R | 0x0 |
| Bits[11:10] | USB State | Interpretation | | | | | | | | | | | | | | | | | |
| 0x0 | SE0 | Not low-speed device, perform EHCI reset. | | | | | | | | | | | | | | | | | |
| 0x2 | J-state | Not low-speed device, perform EHCI reset. | | | | | | | | | | | | | | | | | |
| 0x1 | K-state | Low-speed device, release ownership of port. | | | | | | | | | | | | | | | | | |
| 0x3 | Undefined | Not low-speed device, perform EHCI reset. | | | | | | | | | | | | | | | | | |
| 9 | SUSPENDL1 | When this bit is set to 1, an LPM token is generated. 0: Suspend using L2 1: Suspend using L1 (LPM) | RW | 0 | | | | | | | | | | | | | | | |
| 8 | PR | Port reset This field is 0 if the PP bit is 0. 0x0: Port is not in reset. 0x1: Port is in reset. Write 0x0: Terminate the bus reset sequence. Write 0x1 when at 0x0: The bus reset sequence is started. | RW | 0 | | | | | | | | | | | | | | | |
| 7 | SUS | Suspend This field is 0 if the PP bit is 0. 0x0 when PED = 0x1: Port enabled 0x1 when PED = 0x1: Port in suspend state When PED = 0x0: Port disabled | RW | 0 | | | | | | | | | | | | | | | |

High-Speed Multiport USB Host Subsystem

www.ti.com

| Bits | Field Name | Description | Type | Reset |
|------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 6 | FPR | Force port resume This field is 0 if the PP bit is 0. 0x0: No resume (K-state) detected/driven on port 0x1: Resume detected/driven on port | RW | 0 |
| 5:4 | RESERVED | Reserved | R | 0 |
| 3 | PEDC | Port enabled/disabled change This field is 0 if the PP bit is 0. Read 0x0: No change. Read 0x1: Port enabled/disabled status has changed. Write 0x1: Clears this bit to 0. | RW | 0 |
| 2 | PED | Port enabled/disabled Software cannot enable a port by setting this bit to 1. The host controller only sets this to 1 when the reset sequence determines that the attached device is a high-speed device. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by host software. This field is 0 if the PP bit is 0. 0x0: Disable 0x1: Enable | RW | 0 |
| 1 | CSC | Connect status change Indicates a change has occurred in the port CCS bit. This field is 0 if the PP bit is 0. Read 0x0: No change Read 0x1: Change in current connect status Write 0x1: Clears this bit to 0 | RW | 0 |
| 0 | CCS | Current connect status This value reflects the current state of the port, and may not correspond directly to the event that caused the CSC bit to be set. This field is 0 if the PP bit is 0. 0x0: No device is present. 0x1: Device is present on port. | R | 0 |

23.12 High-Speed USB OTG Controller

This section describes the high-speed USB On-The-Go (OTG) controller of the device.

NOTE: The high-speed USB OTG controller is an instantiation of the MUSBMHDC from Mentor Graphics Corporation.

This document contains materials that are ©2003-2007 Mentor Graphics Corporation.

Mentor Graphics is a registered trademarks of Mentor Graphics Corporation or its affiliated companies in the United States and other countries.

23.12.1 High-Speed USB OTG Controller Overview

The High-Speed USB controller is a high-speed, USB OTG dual-role-device (DRD) link controller supporting the following modes:

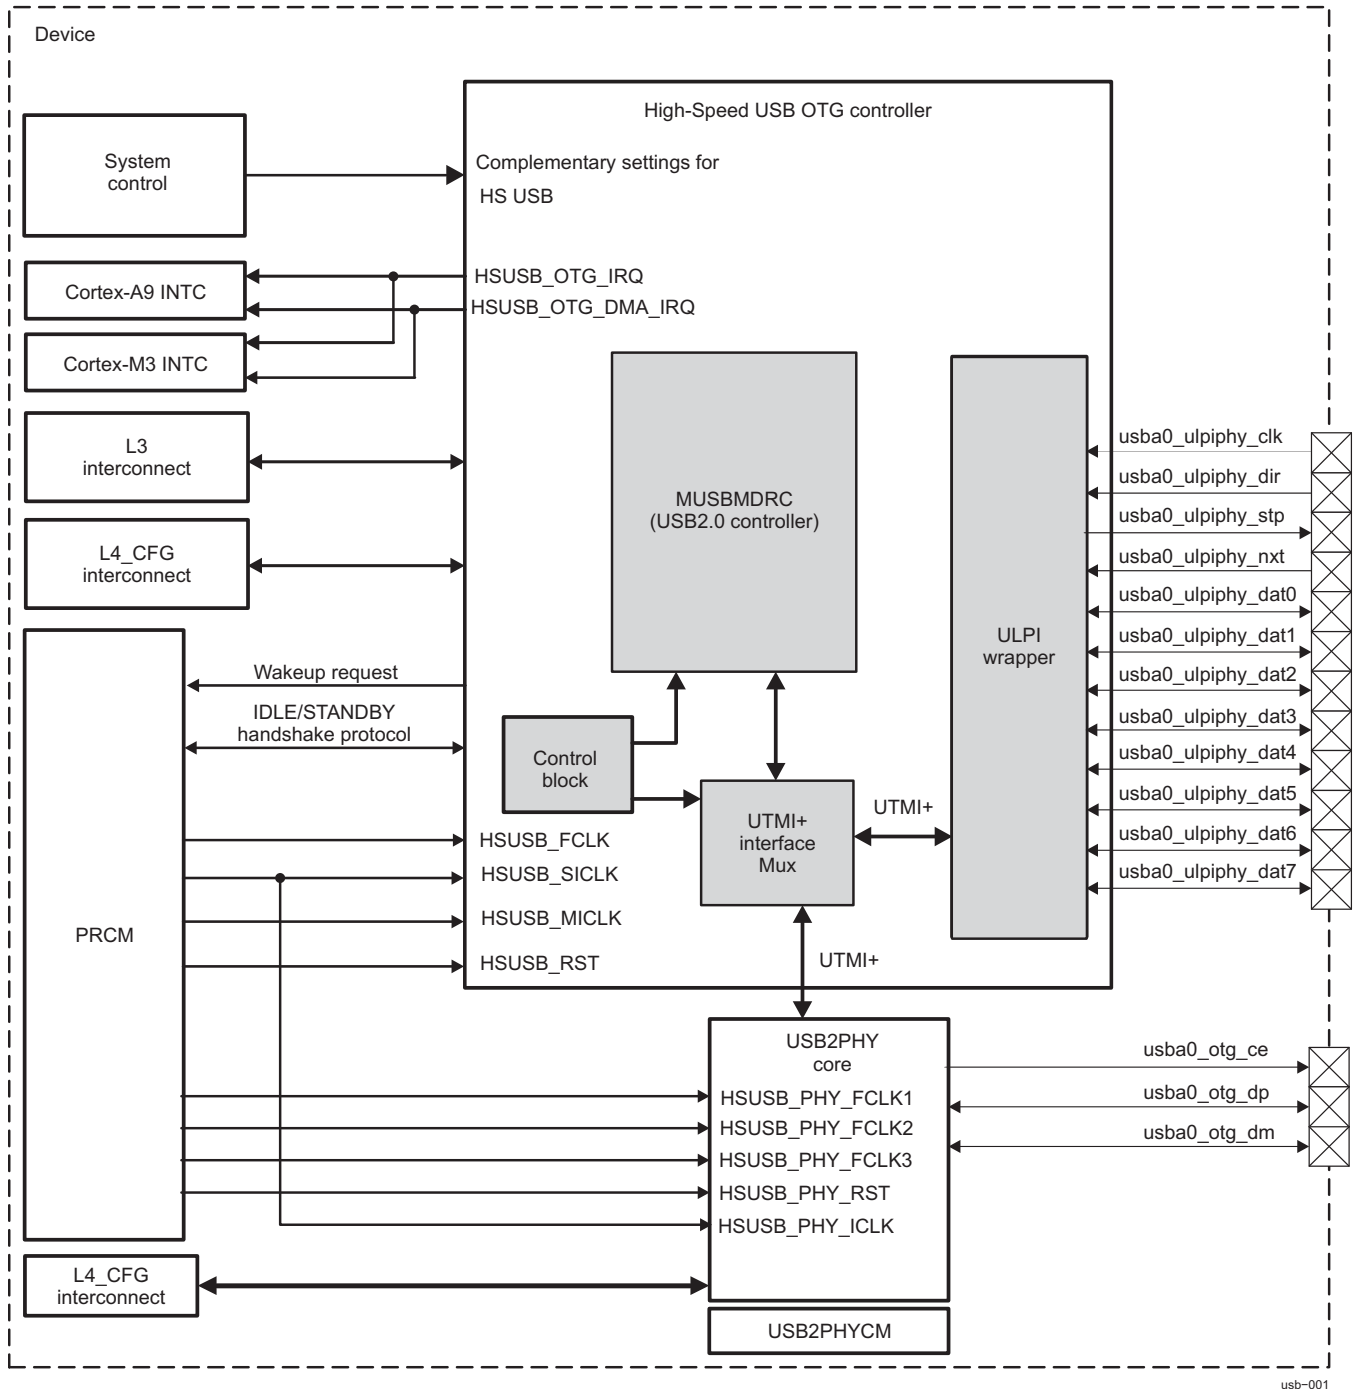

- USB 2.0 peripheral (function controller) in high/full speed (480/12 Mbps, respectively)
- USB 2.0 host in high/full/low speed (480/12/1.5 Mbps, respectively), with one downstream port but multipoint capability when a hub is connected to it (split transaction support, etc.)
- USB 2.0 OTG DRD in high/full speed, with HNP (OTG1.3) and SRP support.

The high-speed USB OTG controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode) and to connect on D+/D- (+ID) USB bus thanks to an embedded USB-HS OTG PHY.

It is connected to L3 master and L4 slave interfaces. It is clocked from independent functional clock from a PHY. This module operates either as the function controller of a high-/full-speed USB peripheral or as the host/peripheral in point-to-point or multi-point communications with other USB functions.

[Figure 23-255](#) highlights the high-speed USB controller.

Figure 23-255. High-Speed USB OTG Controller Highlight

usb-001

23.12.1.1 Main Features

The high-speed USB controller features:

- L3 (master) interface supports:
 - 32-bit data bus width
 - 8/16/32 bit access supported
 - 32-bit address bus width
 - Burst supported
 - WNP not supported
- L4 (slave) interface supports:
 - 32-bit data bus width
 - 16/32 bit access supported
 - 12-bit address bus width
 - Burst not supported
 - WNP supported
- Complies with USB2.0 standard for high-speed (480 Mb/s) functions and with the OTG 1.3 (On-The-Go) supplement. Implement Link Power Management
- Contains embedded HS PHY with battery charger detection
- Contains PHY (physical layer) interface: ULPI interface (12-bit version)
- 15 transmit endpoints and 15 receive endpoints in addition to control endpoint 0
- Supports OTG communications with one or more high/full/low speed devices.
- Supports packet splitting / combining for bulk transfers
- Soft connect/disconnect option
- Performs all transaction scheduling in hardware
- Each endpoint can be configured for types (interrupt, bulk or isochronous), for size and double buffering operation within a limit of a 8KB of data and total RAM size of 16KB.
- Supports high-bandwidth isochronous and interrupt transfers.
- Supports suspend/resume and remote wake-up.
- Two interrupt lines.
- DMA access to endpoint FIFOs with internal DMA controller supporting 8 channels
- Supports host negotiation and session request protocols (HNP (OTG1.3) and SRP)
- CarKit feature implementation

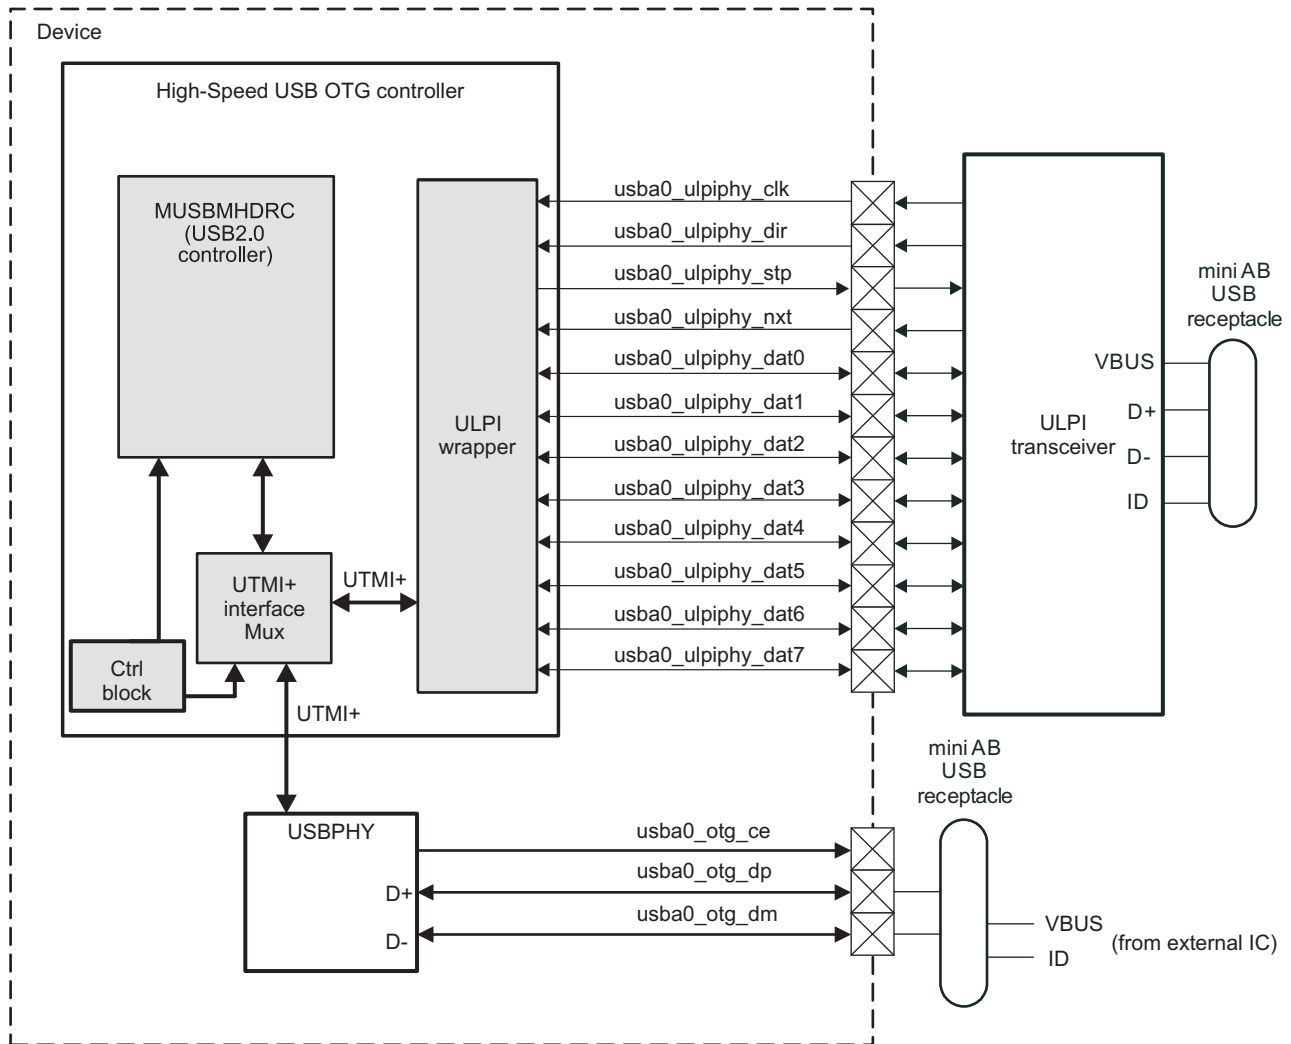

USB-HS OTG PHY (USBPHY). This embedded PHY is composed of two modules:

- USB2PHYCORE contains the USB functions, drivers, receivers and pads for correct D+/D- signalling and the battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable) to control external battery charger.
- USB2PHYCM contains LDO and bandgap for providing voltage reference to USB2PHYCORE module.

23.12.2 High-Speed USB OTG Controller Environment

[Figure 23-256](#) shows a typical application using the high-speed USB controller.

Figure 23-256. High-Speed USB Controller Typical Application System

usb-002

NOTE: Only one interface can be active at a time.

The high-speed USB OTG controller supports a single USB port, which uses the ULPI interface mode, to connect to an off-chip transceiver (12-pin/8-bit data SDR mode). A mini A-B external receptacle allows the connection of an external device.

The 12-pin ULPI interface uses an 8-bit data bus with data synchronous to the rising edge of the PHY clock (SDR mode); the 8-pin ULPI uses a 4-bit data bus with data generated on both the rising and falling clock edge (DDR mode).

The current implementation of high-speed USB controller supports only the 12-pin, 8-bit version ULPI interface. The 12-pin/8-bit data SDR ULPI interface is selected through the `OTG_INTERFSEL[2:0]` PHYSEL field and must be set to 0x1.

Embedded PHY interface is 8-bit, UTMI+ and is selected through setting `OTG_INTERFSEL [2:0]` PHYSEL field to 0x0.

23.12.2.1 High-Speed USB OTG Controller Functional Interfaces

Table 23-1176 describes the I/O signals of the high-speed USB controller interfaces shown in Figure 23-256

Table 23-1176. Input/Output Description

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|---------------------|--------------------|----------------------------------------------------|----------------------------|

23.12.3 High-Speed USB OTG Controller Integration

The L3 (master) interconnect generates data traffic within the device. The L4(slave) interconnect is a configuration port for register setting.

Figure 23-257 shows the high-speed USB controller integration in the device.

Figure 23-257. High-Speed USB Controller Integration

usb-003

Table 23-1177 through Table 23-1179 summarize the integration of the module in the device.

Table 23-1177. Integration Attributes

| Module Instance | Attributes | |
|-----------------|--------------|--------------|

| | HSUSB_OTG_DMA_IRQ | MM_IRQ_61 | Cortex-M3 INTC | HSUSBOTG DMA interrupt request |

23.12.4 High-Speed USB OTG Controller Functional Description

23.12.4.1 Software Reset

The high-speed USB controller has a software reset through the [OTG_SYSCONFIG\[1\] SOFTRESET](#) bit. Writing 0x1 to this bit initiates reset of the module. The bit value 0x1 remains until the reset is complete. When the software reset is complete, the SOFTRESET bit is automatically cleared to 0x0 and has the same effect as the hardware reset. The status of the reset can be observed through the [OTG_SYSSTATUS\[0\] RESETDONE](#) bit.

23.12.4.2 Power Management

23.12.4.2.1 Overview

To save dynamic power consumption, an efficient idle scheme in the device is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated/deactivated safely without complex software intervention. In both cases, the high-speed USB controller power management is applied only to the interface clock domain. The USB OTG functional clock, HSUSB_FCLK, is controlled by the transceiver and is responsible only for a very small percentage of the module overall power consumption.

The high-speed USB controller has both master (initiator) and slave (target) interfaces.

- As an initiator, the high-speed USB OTG controller implements the standby handshake protocol to inform the PRCM module when it enters standby mode and does not generate traffic on the interconnect.
- As a target, the high-speed USB OTG controller implements the IDLE handshake protocol to allow the PRCM module requiring it to enter idle mode.

23.12.4.2.2 System Power Management

23.12.4.2.2.1 Standby Handshake Protocol

The high-speed USB OTG controller can choose to go to standby mode, in which case it stops generating transactions on the interconnect. The module standby leads the PRCM to disable the USB clocks to save power.

The high-speed USB OTG controller has a MSTANDBY handshake mechanism with the PRCM module

The module is ready to enter standby mode (indicated by the MSTANDBY signal to the PRCM asserted) when the USB is in suspend mode and the module is idle. It means the following:

- The module is committed not to start any new transaction on its master interface.
- The module is idle and, therefore, the power manager can start the procedure to turn off the interface clock, if needed. This procedure must be implemented using the slave power-management protocol.

The handshake mechanism lets the module to go to standby state based on the [OTG_SYSCONFIG\[13:12\] MIDDLEMODE](#) field.

- Smart-standby

The high-speed USB controller is configured in smart-standby mode ([OTG_SYSCONFIG\[13:12\] MIDDLEMODE](#) field = 0x2). The module is ready to enter standby mode (MSTANDBY is asserted) when there is no more activity on the USB master interface of the interconnect. MSTANDBY is asserted when the module is idle and deasserted when the module is activated by either an external USB event or an appropriate register access. The module then waits for MWAIT deassertion before a DMA transfer is started.

- Force-standby

– When the high-speed USB controller operates as a host: The [USBOTG.POWER\[1\] SUSPENDMODE](#) bit is set to 0x1 to bring the module to low-power mode (suspend mode). After this setting, the high-speed USB controller waits for its idle state. Software must set

OTG_SYSCONFIG[13:12] MIDDLEMODE = 0x0. Hardware then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:

- Remote wakeup causes a RESUME interrupt
 - Set the USBOTG.POWER[3] RESET bit to 0x1
 - Write 0x2 to the **OTG_SYSCONFIG**[13:12] MIDDLEMODE.
- OR
- Set the USBOTG.POWER[3] RESET bit to 0x1
 - Write 0x2 to the **OTG_SYSCONFIG**[13:12] MIDDLEMODE.
- When the high-speed USB controller operates as a peripheral: When the USB bus is idle for 3 ms, a SUSPEND interrupt is generated by the high-speed USB controller. Software must set **OTG_SYSCONFIG**[13:12] MIDDLEMODE = 0x0. Hardware then asserts MSTANDBY. The high-speed USB controller then asserts MSTANDBY. Similarly, to release the MSTANDBY signal, an appropriate register access must be applied, which can be either of the following two cases:
- Set the USBOTG.POWER[2] RESUME bit to 0x1.
 - Write 0x2 to the **OTG_SYSCONFIG**[13:12] MIDDLEMODE.
- OR
- RESET interrupt is generated by the high-speed USB controller.
 - Write 0x2 to the **OTG_SYSCONFIG**[13:12] MIDDLEMODE.

When MSTANDBY is deasserted as a consequence of the previous register access, the module waits for MWAIT deassertion before a DMA transfer is started.

- No-standby

The high-speed USB controller is configured in no-standby mode (**OTG_SYSCONFIG**[13:12] MIDDLEMODE field = 0x1). The module never enters standby mode (that is, MSTANDBY is never asserted).

Table 23-1180 describes the high-speed USB standby mode settings.

Table 23-1180. HSUSBOTG Host Controller STANDBYMODE Settings

| OTG_SYSCONFIG [13:12] MIDDLEMODE Value | Selected Mode | Description |
|---------------------------------------------------------|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0 | Force-standby | The HSUSBOTG host controller enters standby mode unconditionally |
| 0x1 | No-standby | The HSUSBOTG host controller never enters standby mode |
| 0x2 | Smart-standby | The HSUSBOTG host controller is ready to enter standby mode when there is no more activity on the USB master interface of the interconnect. |

23.12.4.2.2 IDLE Handshake Protocol

The high-speed USB controller can be configured through the **OTG_SYSCONFIG**[4:3] SIDLEMODE field as one of the following acknowledgment modes:

- Smart-idle mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock INIT_L3_ICLK is disabled, see [Section 3.6.10, CD_L3_INIT Clock Domain](#)
- L4 interface clock idle transitions:

Configured in smart-idle mode (**OTG_SYSCONFIG**[4:3] SIDLEMODE field = 0x2), the high-speed USB controller checks for no ongoing activity. The idle acknowledge then is asserted and the module waits for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in smart idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the module is

ready to issue a wake-up request. If a wake-up condition occurs, the high-speed USB controller exits from smart idle mode if the [OTG_SYSCONFIG\[2\] ENABLEWAKEUP](#) bit is set to 0x1 (wake-up capability enabled).

- Smart-idle wake-up mode

The high-speed USB OTG controller is configured in smart-idle wake-up mode ([OTG_SYSCONFIG\[4:3\] Smart Idle Wkp](#) field = 0x3). The functionality of this mode is the same as smart-idle mode, additionally Wake up feature is enabled.

- Force-idle mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock [INIT_L3_ICLK](#) is disabled, see [Section 3.6.10, CD_L3_INIT Clock Domain](#)
- The L4 interface clock idle transitions:

Configured in force-idle mode ([OTG_SYSCONFIG\[4:3\] SIDLEMODE](#) field = 0x0), the high-speed USB controller waits unconditionally for active system clock gating by the PRCM module (this occurs only when all peripherals supplied by the same L3 clock domain are also ready for idle).

Once in idle mode (when the PRCM module gates the interface clock), the module has no activity, the interface clock paths are gated, no interrupt request can be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the high-speed USB controller receives an IDLE request from the PRCM module:

- The interface clock [INIT_L3_ICLK](#) is disabled [Section 3.6.10, CD_L3_INIT Clock Domain](#)
- L4 interface clock idle transitions

Configured in no-idle mode ([OTG_SYSCONFIG\[4:3\] SIDLEMODE](#) bit field = 0x1), the high-speed USB controller module does not go to idle mode and the idle acknowledge is never sent.

[Table 23-1181](#) describes the high-speed USB sidle mode settings. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

Table 23-1181. HSUSBOTG Host Controller SIDLEMODE Settings

| OTG_SYSCONFIG[4:3] SIDLEMODE Value | Selected Mode | Description |
|----------------------------------------------------|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0 | Force-idle | The HSUSBOTG host controller acknowledges unconditionally the IDLE request from the PRCM, regardless of its internal operations. |
| 0x1 | No-idle | The HSUSBOTG host controller never acknowledges any IDLE request from the PRCM. |
| 0x2 | Smart-idle | The HSUSBOTG host controller acknowledges the IDLE request basing its decision on its internal activity. Namely, the acknowledge signal is asserted only when all pending transactions, IRQs or DMA requests are treated. |
| 0x3 | Smart-idle wake-up | The HSUSBOTG host controller enters smart mode with wakeup enabled. |

23.12.4.2.2.3 Wake-Up Request

Wake-up request is enabled by setting [OTG_SYSCONFIG\[2\] ENABLEWAKEUP](#) to 0x1. The enable wake-up feature works only when smart-idle wakeup is enabled.

23.12.4.2.3 Local Power Management

The high-speed USB OTG controller has local power management by internal clock gating features:

- Internal interface clock autogating: Clock for the L3 interconnect logic can be gated when the module is not accessed, if the [OTG_SYSCONFIG\[0\] AUTOIDLE](#) bit is set. Otherwise, this logic is free-running on the interface clock. This bit is used to save power when the module is not used because of the multiplexing configuration selected at the chip level. This bit has precedence over all other internal configuration bits.

23.12.4.3 Inventra MUSBMHDCR

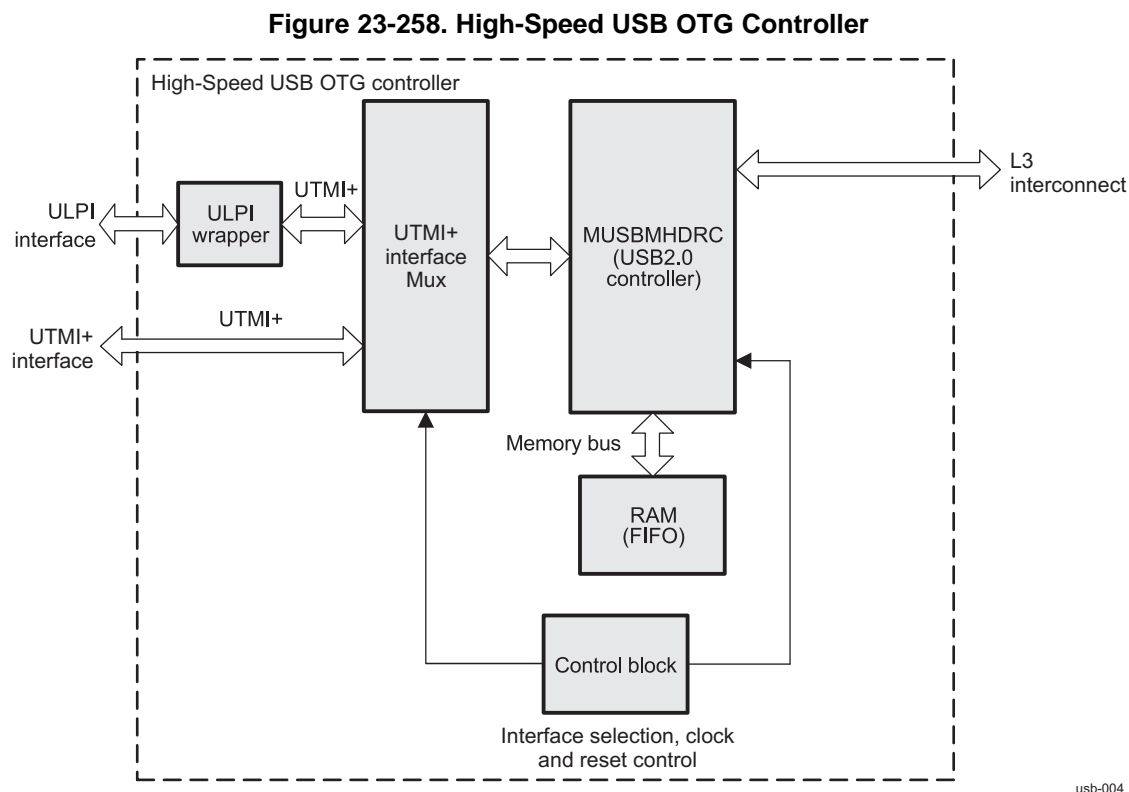

The core functionality of the module is provided by a third-party IP, the Inventra™ MUSBMHDCR from Mentor Graphics® Corporation.

The high-speed USB OTG controller is basically the appropriate adaptation/integration of this IP to comply with TI requirements.

The high-speed USB OTG controller includes the following:

- MUSBMHDCR (USB 2.0 controller)
- Master and slave bridges for conversion AHB to L3 interconnect and L3 interconnect to AHB
- Built-in self-test (BIST) controller
- Two memories (total of 16KB; available for various endpoints)
- Reset and clock generation
- DFT compliance with regards to latest specs

Figure 23-258 shows the high-speed USB controller.

23.12.4.4 Configuration

The following options are implemented in the TI high-speed USB OTG controller:

- 8-bit internal data path processing width (mandated by the use of ULPI)
- 32-bit vcontrol/vstatus support
- External charge pump: Hacked
- Software connect/disconnect supported
- Little-endian and big-endian byte ordering
- Eight DMA channels (with internal DMA initiator implemented)
- Dynamic FIFO sizing enabled
- 16-KB RAM buffer

- 15 IN/OUT endpoints in addition to control endpoint 0
- IN/OUT bulk packet splitting enabled
- High-bandwidth IN/OUT isochronous support enabled (see *Universal Serial Bus Specification Revision 2.0*)

23.12.4.5 Basic Operation

This section provides an overview of the module basic operation.

To implement the most time-critical functions in hardware, the module provides all of the encoding, decoding, and checking required to send and receive USB packets, interrupting the MPU only when endpoint data is successfully transferred. Generally, the following steps are performed.

23.12.4.5.1 Module Initialization

First, the firmware must do the overall initialization of the module by configuring the interrupts, DMA controller, and individual endpoints.

The specific items of a configuration for each endpoint are:

- Direction TX/RX
- Speed: High/full/low
- Special host settings when used in host mode (function address/hub parameters, etc.)
- Transaction protocol: Control/isochronous/bulk/interrupt
- Maximum packet size, that can be transferred through the endpoint
- Whether DMA is required (DMA enable)
- DMA mode
- Start address of the endpoint FIFO within the RAM block
- Maximum packet size allowed
- Whether double-buffering is required. This and the previous option define the amount of space that must be allocated to the FIFO. In the case of double-buffering, the FIFO size is doubled; therefore, the maximum supported size is 8196 bytes for the endpoint FIFOs.

NOTE: On the system level, it must be ensured that the reset and the interface are selected before the functional clock (OTG_60M_FCLK) is applied to the module. Correct functionality is not ensured if a reset deassertion or a change in the interface selection occurs when the functional clock OTG_60M_FCLK is already running.

23.12.4.5.2 Transaction Handling

Depending on whether the module is in the host or peripheral mode, an RX endpoint is assigned to IN or OUT transactions, respectively. Similarly, a TX endpoint is used for IN transactions in the peripheral mode and for OUT transactions in the host mode. When a transaction is complete, the appropriate endpoint interrupt is generated (if enabled).

When a transaction is handled through an RX endpoint, the received packet is placed in the RX FIFO, and the appropriate RX endpoint interrupt is generated. The packet can then be unloaded from the FIFO either manually (that is, by the MPU) or by the DMA. Although an RX endpoint is always active for a peripheral, in host mode the transaction must first be initiated by setting the appropriate request flag (REQPKT). This indicates to the transaction scheduler that there is an active transaction on this endpoint, which requires an IN token to be sent to the target function.

When a transaction is handled through a TX endpoint, the packet to send is loaded into the TX FIFO either manually (that is, by the MPU) or by the DMA. The transaction then must be initiated by setting the appropriate ready flag (TXPKTRDY) to indicate the availability of the new packet. When the packet is successfully sent (scheduled according to the protocol rules), the appropriate TX interrupt is generated.

23.12.4.6 Optional Features

This section gives a quick overview of the optional features that are available, depending on the endpoint configuration.

23.12.4.6.1 Double Packet Buffering

When double packet buffering is enabled (by setting the MSB of the FIFOSZ register) two data packets can be stored in the FIFO. This option can be set for both the TX and RX endpoints in both the peripheral and host mode. For a TX endpoint, double-buffering means that up to two packets can be loaded into the FIFO awaiting transmission; for an RX endpoint, one packet can be received while another is being read. Double packet buffering is especially advisable for isochronous transactions to avoid underrun or overrun errors.

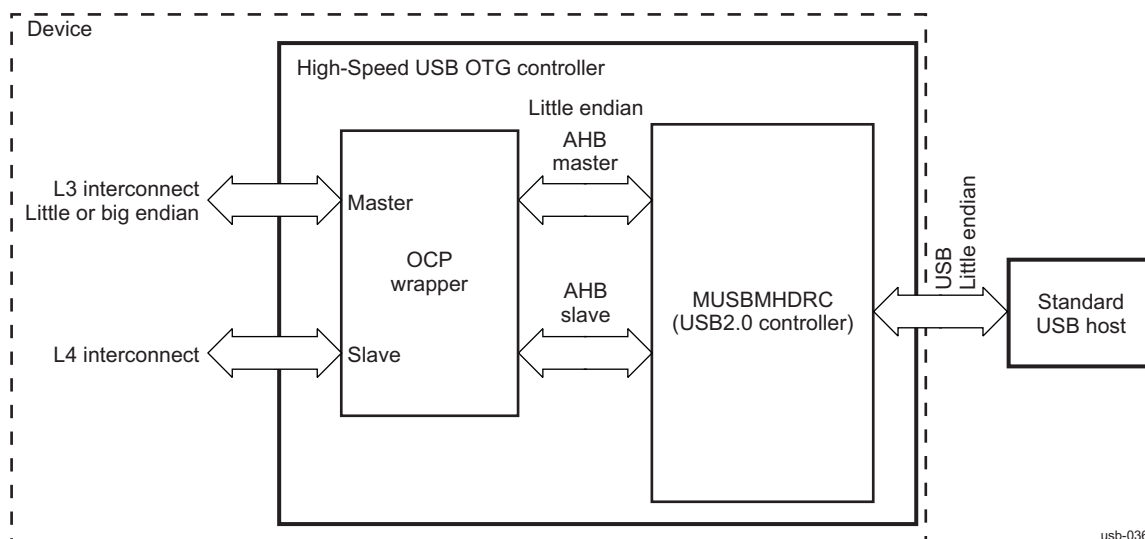

The high-speed USB controller provides dynamic FIFO sizing with an overall RAM size of 16KB, which can then be allocated to the different endpoints when the module is initialized. The maximum size of an endpoint FIFO is 4096 bytes for single packet buffering and 8192 bytes for double packet buffering. The firmware must ensure that a block of RAM is properly assigned to all TX and RX endpoints, considering the total RAM size and the maximum packet size set for the endpoint.

23.12.4.6.2 USBOTGHS Support for Big Endian

In the example in [Figure 23-259](#), the high-speed USB OTG controller module is configured as a USB device and is connected to a standard USB host. The two interconnect interfaces of the high-speed USB OTG controller connect it to the system bus. The register read/write is performed through the interconnect slave interface (control path). The data transfer to/from system memory takes place through the interconnect master interface (data path).

The data transfer on USB is always in little-endian mode, but on interconnect it can be in little- or big-endian mode, as shown in [Figure 23-259](#).

Figure 23-259. High-Speed USB OTG Controller Endianness

Big-endian support in the high-speed USB OTG controller may or may not require byte-swapping in the data path. Byte-swapping is performed based on the unit size of data. For example, if multiple bytes are packed into a single 32-bit word, these bytes must be swapped in a big-endian interconnect. On the other hand, if the data is simply a 32-bit word (for example, a 32-bit descriptor pointer in a memory buffer), the bytes in the word must not be swapped in big-endian mode.

In the high-speed USB OTG controller, the unit size of descriptors/descriptor pointers is 32 bits, and the unit size of USB data is 8 bits. Four 8-bit USB data are packed to form a 32-bit word. This 32-bit data requires byte-swapping, whereas the descriptors/descriptor pointers do not require byte-swapping.

NOTE: Byte-swapping is not required in the control path (slave interface).

The interconnect master interface (a submodule within the interconnect wrapper) supports big-endian conversion by setting the `OTG_BIGENDIAN[0]` `BIG_ENDIAN` bit to 0x1.

For interconnect write transactions, the data word is swapped, as shown in [Table 23-1182](#), before its output on the interconnect master interface. In case of an interconnect read transaction, the received data is swapped before its output on the AHB master interface of the MUSBMHDRC core. The interconnect MByteEn is swapped before the command is issued on the interconnect master interface. The interconnect MAddr is always aligned to the size of the interconnect data (32 bits). Hence, the interconnect MAddr is always word-aligned.

Table 23-1182. Interconnect Data and MByteEn in Little- and Big-Endian Modes

| Unit Size of Data | AHB Size (of Packed/Nonpacked Data) | AHB Start Address Offset (Always in Little-Endian Mode) | Interconnect MByteEn in Little-Endian Mode | Interconnect MByteEn in Big-Endian Mode | Interconnect Data in Little-Endian Mode | Interconnect Data in Big-Endian Mode |
|-------------------|-------------------------------------|---------------------------------------------------------|--------------------------------------------|-----------------------------------------|-----------------------------------------|--------------------------------------|
| Byte | Byte | 0 | 0001 | 1000 | xxx b 0 | b0xxx |
| Byte | Byte | 1 | 0010 | 0100 | xx b 0x | xb0xx |
| Byte | Byte | 2 | 0100 | 0010 | x b 0xx | xxb0x |
| Byte | Byte | 3 | 1000 | 0001 | b0xxx | xxx b 0 |
| Byte | Half-word | 0 | 0011 | 1100 | xx b 1b0 | b0b1xx |
| Byte | Half-word | 2 | 1100 | 0011 | b1 b 0xx | xxb0b1 |
| Byte | Word | 0 | 1111 | 1111 | b3b2b1b0 | b0b1b2b3 |
| Half-word | Half-word ⁽¹⁾ | 0 | 0011 | 1100 | xx b 1b0 | b1b0xx |
| Half-word | Half-word ⁽¹⁾ | 2 | 1100 | 0011 | b1 b 0xx | xxb1b0 |
| Half-word | Word ⁽¹⁾ | 0 | 1111 | 1111 | b3b2b1b0 | b1b0b3b2 |
| Word | Word ⁽²⁾ | 0 | 1111 | 1111 | b3b2b1b0 | b3b2b1b0 |

⁽¹⁾ Not a likely scenario for high-speed USB OTG controller

⁽²⁾ Corresponds to descriptor and descriptor pointer. No bytes are packed to form a word; hence, no byte-swapping is done in this case.

23.12.4.6.3 DMA

The high-speed USB controller has an internal DMA controller for efficient loading/unloading of the endpoint FIFOs. The DMA controller is configured for 8 channels and it has its own block of control registers and its own interrupt controller

If the DMA is enabled for a TX endpoint, a DMA transfer occurs whenever the endpoint can accept another packet in its FIFO (that is, the DMA controller loads the packets into the FIFO without processor intervention).

If the DMA is enabled for an RX endpoint, a DMA transfer occurs whenever the endpoint has a packet in its FIFO (that is, the DMA CONTROLLER unloads the packets from the FIFO without processor intervention).

The high-speed USB controller supports two DMA request modes, which also affects the generation of endpoint interrupts.

- DMA request mode 0 is especially advisable for isochronous transfers but can also be used for bulk and interrupt transfers.
- DMA request mode 1 is mainly valuable for bulk transfers, where typically a large block of data is split into a series of packets of the maximum size.

23.12.4.6.3.1 DMA Request Mode 0

For RX endpoints, the DMA transfer is initiated when a data packet is available in the endpoint FIFO. The appropriate endpoint interrupt is also generated after the packets are received.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is also generated to prompt the loading of the packets.

23.12.4.6.3.2 DMA Request Mode 1

For RX endpoints the DMA transfer is initiated only when the received packet is the maximum packet size (as set in the RXMAXP register for the corresponding endpoint). The appropriate endpoint interrupt is generated only when the received packet is a short packet (that is, one less than the maximum packet size); otherwise, it is suppressed.

For TX endpoints, the DMA transfer is initiated when the endpoint FIFO can accept a data packet. The appropriate endpoint interrupt is suppressed.

23.12.4.6.3.3 Internal DMA Controller

The high-speed USB controller has an internal DMA controller to perform DMA transfers acting as host on the L3 interconnect. The DMA controller has eight channels, which can be independently programmed based on the following configuration options:

- DMA enable
- Direction (DMA write/DMA read)
- DMA mode (transfer one or more packets)
- Interrupt enable
- Endpoint number
- L3 interconnect memory address (32 bits)
- Byte count

The DMA controller can issue single accesses (8-bit, 16-bit, or 32-bit) and also bursts (4 × 32-bit, 8 × 32-bit, or 16 × 32-bit) on the L3 interconnect. The start address provided to the DMA controller must be 32-bit aligned.

23.12.4.7 Automatic Packet Splitting/Combining for Bulk Transfers

The high-speed USB controller offers the facility for bulk endpoints to store larger amounts of data in their FIFOs than can be transferred in a single USB operation. In other words, the module includes a configuration option that, if selected, allows larger data packets to be written to bulk TX endpoints, which are then split into packets of an appropriate size for transfer across the USB. A similar option exists for bulk RX endpoints, which, if selected, causes the module to combine the packet received across the USB into larger data packets before being read by the application software.

The firmware can enable these options by setting the corresponding bits (MPRXE and MPTXE) in the CONFIGDATA register. The necessary packet size information contains the payload size for one transaction and a multiplier defining the maximum number of USB packets. The payload is required to be either 8, 16, 32, 64, or (in case of high-speed transfers) 512 bytes; the multiplier can be any value up to 32.

23.12.4.8 High-Bandwidth Isochronous Endpoints

In the high-speed mode, isochronous endpoints can transfer up to three USB packets in any microframe with a payload of up to 1024 bytes in each packet, corresponding to a data transfer rate of up to 3072 bytes per microframe (see *Universal Serial Bus Specification Revision 2.0*).

For TX endpoints, the high-speed USB controller supports this by allowing loading data packets of up to 3072 bytes (that is, 3 × 1024 bytes) into the associated endpoint FIFO, which is then automatically split into USB packets of the maximum payload, or smaller to be transmitted in one microframe.

For RX endpoints, the module automatically combines all the USB packets received during a microframe into a single packet of up to 3072 bytes (that is, 3 × 1024 bytes) within the RX FIFO.

The number of USB packets transferred per microframe and the maximum payload in each packet is defined through the appropriate registers (RXMAXP and TXMAXP).

23.12.4.9 Carkit Implementation

Carkit feature implementation:

UART3 RX/TX muxing on the usba0_ulpihy_dat0 and usba0_ulpihy_dat1. To support carkit interrupt through USB0HS.DATA3, three different methods can be used:

- External PHY interrupt if provided: IRQ_SYS interrupt
- UART3 interrupt: CTS edge detection
- GPIO interrupt: Edge detection on GPIO associated to usba0_ulpihy_dat3 line

23.12.4.10 USB PHY

The device-embedded USB PHY is composed of the following modules:

- USB2PHYCORE: Contains the USB functions, drivers, receivers, and pads for correct D+/D– signaling, and the battery charger detection (supporting dead-battery mode). Delivers a 3.3-V output signal (charger enable [pin usba0_otg_ce]) to control an external battery charger.
- USB2PHYCM: Contains LDO and bandgap to provide voltage reference to the USB2PHYCORE module

The embedded PHY does not support the OTG features of USB-OTG standards (that is, ID pin detection and VBUS detection). This function is exported to an external companion chip (for example, the TWL6030). Software must retrieve the OTG HNP and SRP status from the TWL6030 (using the I2C1 interface) and configure the bits inside the control module that drive the related USBOTGHS UTMI+ interface signals. It must also read back the UTMI+ signals needed to configure the TWL6030 OTG module.

These signals are:

- Inputs of the USB controller driven by the control module:
 - Avalid: Indicates whether VBUS is above the A-Device session valid threshold
 - Bvalid (currently not used)
 - Vbusvalid: Indicates whether VBUS is above the threshold for normal operation
 - Sessend: Indicates whether VBUS is below the B-Device session end threshold
 - Iddig: Indicates the value of the ID pin of the USB connector
- Outputs of the USB controller readable in the control module:
 - Idpullup: Enables sampling of the ID pin of the USB connector
 - Drv vbus: Controls the driving of 5-V power on VBUS
 - Chrg vbus: Controls the charging of VBUS for initiating SRP
 - Dischrg vbus: Controls the discharging of VBUS for completing SRP

See the CONTROL_USBOTGHS_CONTROL register in [Chapter 18, Control Module](#), and the TWL6030 documentation.

The following UTMI signals are not connected:

- Txbitstufferable (no bit-stuffing out from the USB controller)
- Txbitstufferableh (because only 8 bits are used)

The following USBPHY signals are routed internally to the GPIO6 module pins to generate interrupts when any of the following events occur:

- CHGDETECTED: This signal indicates the output of the charger detection protocol.

0: Charger not detected

1: Charger detected

The value is latched until the charger protocol is reset.

- DPDM5VSHORT: This signal is asserted high if a short-circuit-to-VBUS condition is detected on the USB DP or DM pins. This signal is valid only if all power supplies are present. The short is detected if any or even none of the supplies are present.

0: No short

1: VBUS short on DP or DM detected

For information about how to enable these interrupts, see [Chapter 25, General-Purpose Interface](#).

The USBPHY internal registers are listed in [Section 23.12.6.3, USBPHY Registers](#), for debug purposes.

CAUTION

For a correct read out of the USBPHY registers, the value of the [OCP2SCP_TIMING\[3:0\]](#) SYNC2 bit field must be set to 0x6 or more, and the [OCP2SCP_TIMING\[9:7\]](#) DIVISIONRATIO bit field must be left untouched.

23.12.5 High-Speed USB OTG Controller Basic Programming Model

This section describes the low-level hardware programming sequences for configuration and use of the high-speed USB OTG controller.

23.12.5.1 Global Initialization

23.12.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the high-speed USB OTG controller is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the high-speed USB OTG controller.

Table 23-1183. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRCM | All required clocks must be enabled, see Table 23-1178 . Do not apply OTG_60M_FCLK clock before the interface is selected. Refer to Section 3.6.3.2, CM Clock Source , in Chapter 3, Power, Reset, and Clock Management . |
| Cortex-A9 MPU INTC or Cortex-M3 MPU INTC | Cortex-A9 MPU or Cortex-M3 MPU interrupt controller must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the High-Speed Multiport USB Host Subsystem. See the respective Functional Description in the Interrupt Controller chapter for the MPUs. |
| Interconnect (L3 and L4) | See Section 13.2, L3 Interconnect , and Section 13.3, L4 Interconnect , for more information. |

23.12.5.1.2 High-Speed USB OTG Controller Global Initialization

This procedure initializes the high-speed multiport USB host subsystem after a power-on or software reset. The module USBPHY is reset through boundary reset signal L3_INIT_RST coming from PRCM module.

Table 23-1184. High-Speed USB OTG Software Reset

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------------------|--------------------------------------------|-------|
| Perform a software reset on the USB OTG controller | OTG_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset is finished | OTG_SYSSTATUS[0] RESETDONE | =0x1 |

Table 23-1185. Power Management Configuration

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------|-------------------------------------------------|-------|
| Select master interface standby mode | OTG_SYSCONFIG[13:12] MIDDLEMODE | 0x- |
| Select slave interface idle mode | OTG_SYSCONFIG[4:3] SIDLEMODE | 0x- |

Table 23-1185. Power Management Configuration (continued)

| Step | Register/Bit Field/Programming Model | Value |
|----------------------|--------------------------------------|-------|
| Set clock autogating | OTG_SYSCONFIG[0] AUTOIDLE | 0x- |

23.12.5.2 High-Speed USB OTG Controller Interface Modes

This procedure describes TI high-speed USB controller interface selection:

Table 23-1186. High-Speed USB Controller Interface Selection

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------------------|------------------------------------------|-------|
| Select between embedded and external PHY interface | OTG_INTERFSEL[2:0] PHYSEL | 0x- |
| Enable functional PHY clock (OTG_60M_FCLK) | Refer to Section 3.6.3.2 | - |

23.12.5.3 High-Speed USB OTG Controller Power Management Configuration

This section describes the settings for optimal high-speed USB controller power management, depending on the use of this module in the application.

23.12.5.3.1 No Application Mode

The optimal configuration when the high-speed USB controller is not used by the application is as follows:

Table 23-1187. Power Management Configuration - No Application Mode

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------------------------------------------------|--------------------------------------|-------|
| Switch master interface to force standby mode | OTG_SYSCONFIG[13:12] MIDDLEMODE | 0x0 |
| Switch slave interface to force-idle mode | OTG_SYSCONFIG[4:3] SIDLEMODE | 0x0 |
| Set the clock to smart mode - clock is cut-off if no activity on the interface | OTG_SYSCONFIG[0] AUTOIDLE | 0x1 |

23.12.5.3.2 Host or Peripheral Mode

When used as a host or in peripheral mode, the high-speed USB controller must be programmed as follows:

Table 23-1188. Power Management Configuration - Host or Peripheral Mode

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------------------------------------------------|--------------------------------------|-------|
| Switch Master interface to smart standby mode | OTG_SYSCONFIG[13:12] MIDDLEMODE | 0x2 |
| Switch Slave interface to smart-idle mode | OTG_SYSCONFIG[4:3] SIDLEMODE | 0x2 |
| Set the clock to smart mode - clock is cut-off if no activity on the interface | OTG_SYSCONFIG[0] AUTOIDLE | 0x1 |

23.12.5.3.3 Switching Between Host and Peripheral Mode

When used as a host/peripheral, the high-speed USB OTG controller must be programmed as follows:

Table 23-1189. Power Management Configuration - Switching Between Host and Peripheral Mode

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------------------------------------------------|--------------------------------------|-------|
| Switch Master interface to force standby mode | OTG_SYSCONFIG[13:12] MIDDLEMODE | 0x0 |
| Switch Slave interface to smart-idle mode | OTG_SYSCONFIG[4:3] SIDLEMODE | 0x2 |
| Set the clock to smart mode - clock is cut-off if no activity on the interface | OTG_SYSCONFIG[0] AUTOIDLE | 0x1 |

23.12.6 High-Speed USB OTG Controller Register Manual

This section presents only the TI-specific registers of the high-speed USB controller.

Table 23-1190 lists the base address and address space for the high-speed USB controller.

Table 23-1190. High-Speed USB OTG Controller Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|------------|

23.12.6.3 USBPHY Registers

23.12.6.3.1 USBPHY Register Summary

CAUTION

The USBPHY registers are limited to 32-bit data accesses; 16- and 8-bit accesses are not allowed and can corrupt register content.

Reserved bit fields must not be modified.

NOTE: No USB2PHY register settings need to be done in order USB2PHY to operate in default USB2.0 (HS, FS, or LS mode) condition. Registers are provided only for debug purposes.

23.13 Full-Speed USB Host Controller

This section describes the full-speed universal serial bus (FSUSB) host controller for the device.

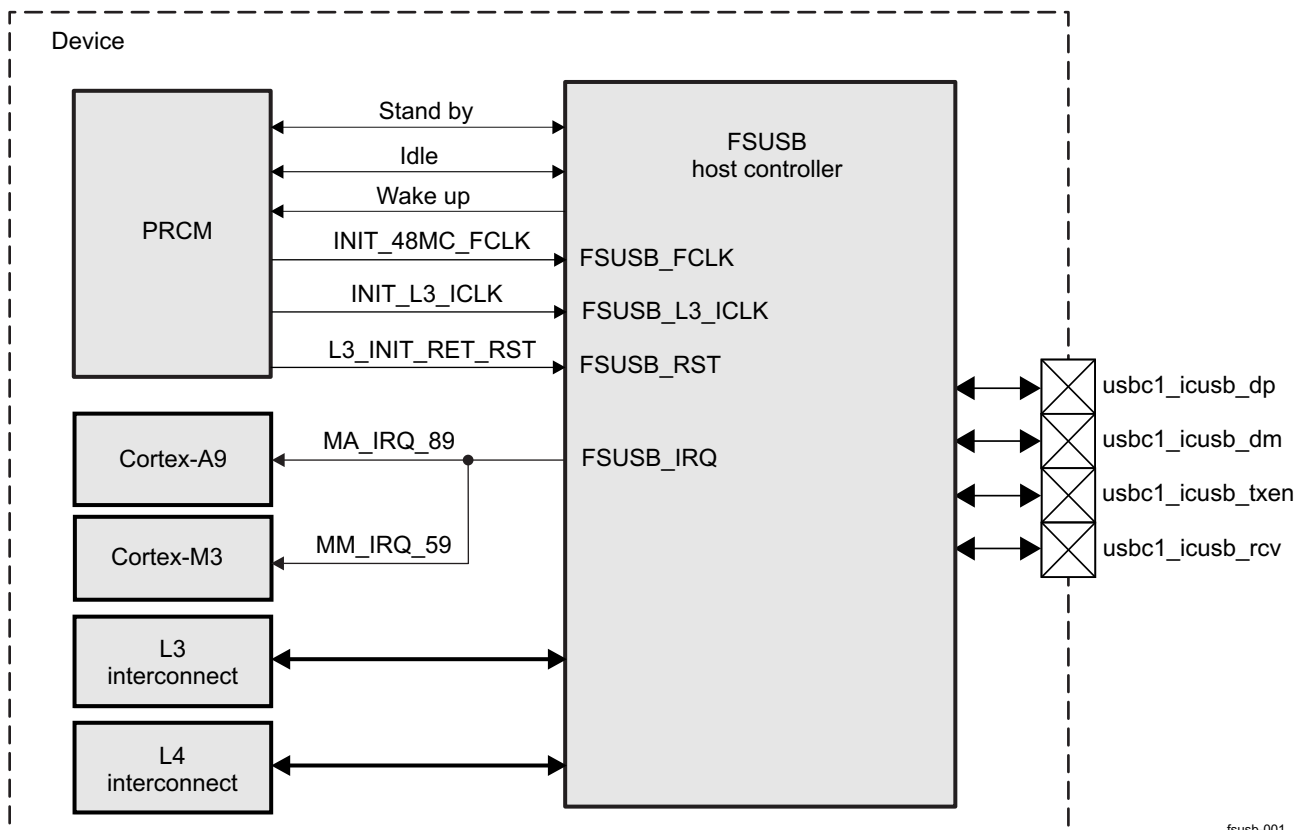

23.13.1 FSUSB Host Controller Overview

NOTE: Copyright ©2004, 2005, 2006, 2007, 2008 Synopsys, Inc. All rights reserved. Used with permission.

This module is a full-speed universal serial bus (FSUSB) host controller which complies with the USB 2.0 standard for full-speed functions. The FSUSB host controller supports a single universal serial bus (USB) host port with a USB interchip to interface with a multimedia subscriber-identity module (SIM) card, using 2-/4-pin bidirectional mode (host mode).

The FSUSB host controller has level 3 (L3) and level 4 (L4) interfaces with an independent functional clock.

Figure 23-260. FSUSB Host Controller Overview

fsusb-001

23.13.1.1 Main Features

The main features of the FSUSB host controller include:

- USB host
 - Compatible with OHCI Rev 1.0
 - USB 2.0 low-speed (1.5 Mbps) and full-speed (12 Mbps) operations
 - Single port
- USB port signal pins interface:
 - Only supports the 2-/4-pin (bidirectional) mode
- Slave interface (L4) supporting:

- 32-bit data bus width
- 32-bit access
- 32-bit address bus width
- Wireless network portability (WNP)
- Burst is not supported
- Master interface (L3) supporting:
 - 32-bit data bus width
 - 8-/32-bit access
 - 32-bit address bus width
 - Write nonposted (WRPN) interconnect transaction

23.13.2 FSUSB Host Controller Environment

This section describes the FSUSB host controller application fields from an environment point of view (external connections). It discusses FSUSB host controller connectivity options, lists all possible interfaces, and describes the protocol and data format used in each case.

Figure 23-261 shows the output pins of the FSUSB host controller.

Figure 23-261. Overview of FSUSB Host Controller Environment

23.13.2.1 FSUSB Host Controller Functional Interfaces Description

Table 23-1228 and Table 23-1229 list the input/output (I/O) signals.

Table 23-1228. Pin List for FS USB-Host (USB-Interchip Mode)

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value |

| usbc1_icusb_dm | I/O | FSUSB host controller D minus | Unknown |
| usbc1_icusb_txen | O | FSUSB host controller transmit enable | Unknown |
| usbc1_icusb_rcv | I | FSUSB host controller receive | Unknown |

⁽¹⁾ I = Input, O = Output

23.13.3 FSUSB Host Controller Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 23-262 shows the integration of the FSUSB host controller in the device.

Figure 23-262. FSUSB Host Controller Integration

Table 23-1230 through Table 23-1232 summarize the integration of the module in the device.

Table 23-1230. Integration Attributes

| Module Instance | Attributes | |
|-----------------------|--------------|--------------|
| | Power Domain | Interconnect |
| FSUSB host controller | PD_L3_INIT | L3 L4_CFG |

Table 23-1231. Clocks and Resets

| Clocks | | | | |
|-----------------------|-------------------------|--------------------|--------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| FSUSB host controller | FSUSB_FCLK | INIT_48MC_FCLK | PRCM | Functional clock (see Section 3.6.10, <i>CD_L3_INIT Clock Domain</i> in Chapter 3, <i>Power, Reset, and Clock Management</i>). |
| | FSUSB_L3_ICLK | INIT_L3_ICLK | PRCM | L3 interconnect clock for the L3 master port interface (see Section 3.6.10, <i>CD_L3_INIT Clock Domain</i> in Section 3.6.10, <i>Power, Reset, and Clock Management</i>). |

Table 23-1231. Clocks and Resets (continued)

| Clocks | | | | |
|-----------------------|-------------------------|--------------------|--------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| | FSUSB_L4_ICLK | INIT_L4_ICLK | PRCM | L4 interconnect-enable signal for the slave interface on L4 (see Section 3.6.3.2 , <i>CM Clock Source</i> in Chapter 3 , <i>Power, Reset, and Clock Management</i>) |
| Resets | | | | |
| FSUSB host controller | FSUSB_RST | L3_INIT_RET_RST | PRCM | This signal resets the FSUSB host controller module. |

Table 23-1232. Hardware Requests

| Interrupt Requests | | | | | |
|--------------------|--------------------|-------------------------|----------------|------------------------------------------------------|--|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description | |
| FSUSB controller | host FSUSB_IRQ | MA_IRQ_89 | Cortex-A9 INTC | Destination is Cortex-A9 interrupt controller (INTC) | |
| | FSUSB_IRQ | MM_IRQ_59 | Cortex-M3 INTC | Destination is Cortex-M3 INTC | |

NOTE: For interrupt source information, see [Section 23.13.5.1.2](#), *Interrupt Requests*.

23.13.4 FSUSB Host Controller Functional Description

23.13.4.1 Resets

The different software reset functions of the FSUSB host controller are controlled by the following register bits:

- **HCOCPYSYS[1] SOFT_RESET** bit: Writing 0x1 to this bit resets the entire module, except IDLE, STANDBY, and DISCONNECT logic. The bit value of 0x1 remains until the reset completes. When the software reset completes, the SOFT_RESET bit is automatically set to 0x0.
- **HCCOMMANDSTATUS[0] HCR** bit: Writing 0x1 resets most of the open host controller interface (OHCI) registers of the FSUSB host controller. It is useful for error handling only. OHCI register accesses must not be attempted until a read of this register returns 0x0.

23.13.4.2 Power Management

23.13.4.2.1 Features

The power management module has the following features:

- The FSUSB host controller has one instance of IDLE and standby interface.
- There are separate disconnect interfaces for master and slave ports.
- The PRCM module uses IDLE protocol to put the FSUSB host controller asynchronous into idle mode.
- The FSUSB host controller uses standby protocol for USB suspend event.
- Clock gating is done externally for IDLE and standby protocol.
- The IDLE and STANDBY interfaces are synchronous to the PRCM clock.

23.13.4.2.2 IDLE Protocol

The IDLE protocol has the following features:

- There is one IDLE protocol for the FSUSB host controller.
- The **HCOCPYSYS[3:2] IDLE_MODE** bit field controls the way USBFSHOST handles the IDLE protocol.
- The FSUSB host controller WakeupEnable mode is enabled by setting the **HCOCPYSYS[3:2] IDLE_MODE** bit field to 0x11.
- Wakeup is generated asynchronously in the FSUSB host controller. To detect the USB remote wakeup, the FSUSB host controller should always be powered up (that is, the clocks can be off, but the power is needed for a wake-up detection to work).
- The FSUSB host controller interface asserts wakeup from suspend when the wake-up conditions occur (such as remote signaling on port, device connect/disconnect) and the FSUSB host controller is in idle mode. The FSUSB host controller interface deasserts the wake-up signal when the PRCM module has serviced the event (usually at completion of a resume sequence on the USB) and IDLE request is 0.
- The FSUSB host controller interface acknowledges and goes into IDLE only if the host controller is in suspend mode, or if force-idle mode is enabled.

Table 23-1233 lists the FSUSB host controller idle mode settings.

Table 23-1233. FSUSB Host Controller Idle Mode Settings

| SIDLEMODE Value | Selected Mode | Description |
|-----------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0 | Force-idle | The high-speed USB host controller unconditionally acknowledges the IDLE request from the PRCM module, regardless of its internal operations. |
| 0x1 | Not supported (no-idle) | |
| 0x2 | Smart-idle | The high-speed USB host controller acknowledges the IDLE request, basing its decision on its internal activity. Namely, the acknowledged signal is asserted only when all pending transactions, IRQs, or DMA requests are treated. |
| 0x3 | Smart-idle wakeup | The high-speed USB host controller enters smart mode with asynchronous wakeup enabled. |

23.13.4.2.3 Standby Protocol

The Standby protocol is associated with FSUSB host controller suspend. Standby assertion is linked with Suspend, and Wakeup assertion is linked with remote wakeup. When the application wants to resume the USB, the power manager must initiate the wakeup using the Standby protocol.

- There is one Standby protocol for the FSUSB host controller.
- The `HCOCPSYS[5:4] STANDBY_MODE` bit field controls the way USBFSHOST handles the Standby protocol.
- The FSUSB host controller wakes up with standby, and stays in standby until the host core becomes functional.

Table 23-1234 lists the STANDBY_MODE settings for the FSUSB host controller.

Table 23-1234. FSUSB Host Controller STANDBY_MODE Settings

| MIDLEMODE Value | Selected Mode | Description |
|-----------------|----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x0 | Force-standby | The high-speed USB host controller enters standby mode unconditionally (Mstandby is asserted unconditionally). |
| 0x1 | Not supported (no-standby) | |
| 0x2 | Smart-standby | The high-speed USB host controller is ready to enter standby mode when there is no more activity on the USB master interface of the interconnect. |
| 0x3 | Smart-standby wakeup | The high-speed USB host controller enters smart mode with asynchronous wakeup enabled. |

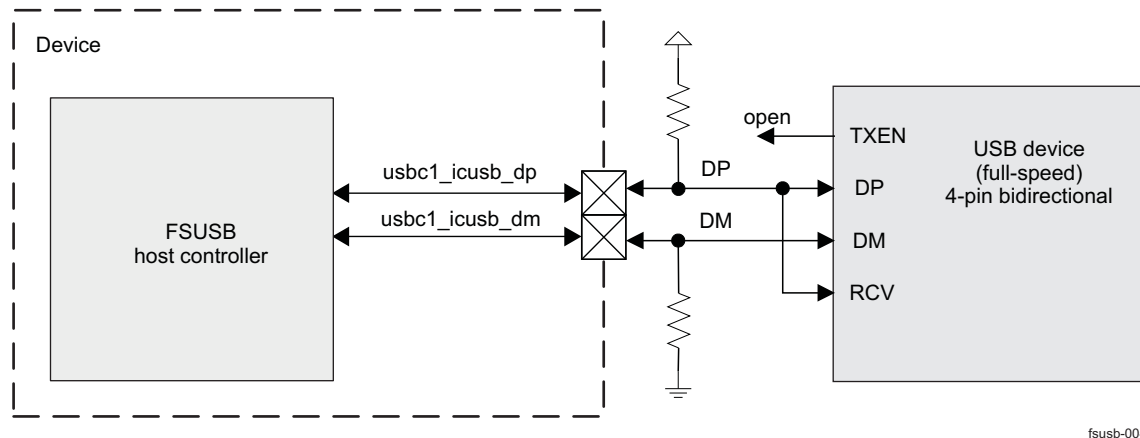

23.13.4.3 FSUSB Host Controller Bidirectional Interface Modes

Bidirectional SIM interface modes are implemented using existing bidirectional modes. Their goal is to reduce pin count with respect to 6-/5-pin modes.

Pullup/pulldown resistors on the bidirectional lines are compulsory, because the lines are not constantly driven from one side or the other of the interface. In this case, the pullup on one of the two lines triggers the connect signal from the device to the host. The pullup can be controlled (by the USB device side) or hardwired. In the first case, the USB host sees only the external device if the pullup is active; in the second case, the USB host sees the device as soon as software enables the port in question.

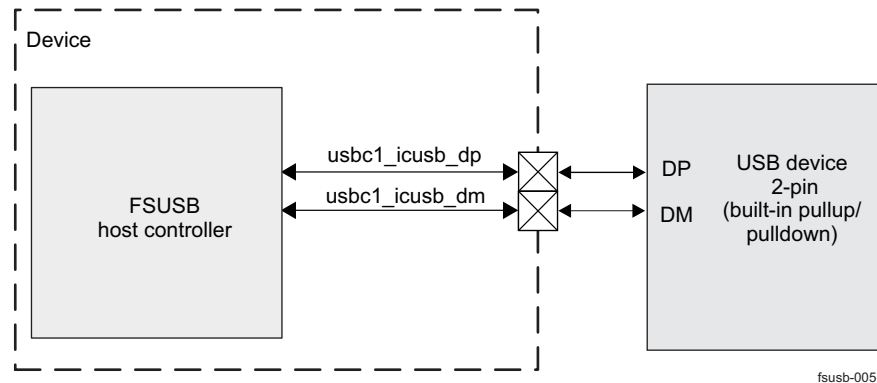

The device supports the 2-pin bidirectional SIM Interface mode with DP/DM encoding. Figure 23-263 shows a USB port using DP/DM encoding.

Figure 23-263. 2-Pin Bidirectional Interface Using DP/DM Encoding With a Standard 4-Pin Bidirectional USB Device

A specific 2-pin USB device can also be implemented with just the two bidirectional pins. Figure 23-264 shows an example in DP/DM encoding with built-in pullup/pulldown resistors.

Figure 23-264. 2-Pin Bidirectional Interface Using DP/DM Encoding With a Specific 2-Pin Bidirectional USB Device

23.13.5 FSUSB Host Controller Basic Programming Model

This section describes the low-level hardware programming sequences for the configuration and use of the FSUSB host controller.

23.13.5.1 Global Initialization

23.13.5.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the FSUSB host controller is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the FSUSB host controller.

[Table 23-1235](#) describes the global initialization of the surrounding modules.

Table 23-1235. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRCM | All clocks must be enabled (see Table 23-1231). See Section 3.6.3.2, CM Clock Source in Chapter 3, Power, Reset and Clock Management . |
| Cortex-A9 MPU INTC or Cortex-M3 MPU INTC | The Cortex-A9 MPU or Cortex-M3 MPU INTC must be configured to enable the interrupt request generation to the Cortex-A9 MPU or Cortex-M3 MPU subsystem when interrupt requests are generated by the FSUSB host controller. See the respective functional description in Chapter 17, Interrupt Controllers , for the MPUs. |
| Interconnect (L3 and L4) | For more information, see Section 13.2, L3 Interconnect , and Section 13.3, L4 Interconnect . |

NOTE: This module requires an active functional clock for L4 access to function.

23.13.5.1.2 FSUSB Host Controller Global Initialization

This procedure initializes the FSUSB host controller after a power-on or software reset (see [Table 23-1236](#)).

Table 23-1236. High-Speed Multiport USB Host Subsystem Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------------------------------------------------------------------------------|--------------------------------------|-------|
| Perform a software reset on the FSUSB host controller module, except for IDLE, STANDBY, and DISCONNECT logics. | HCOCPSYS[1] SOFT_RESET | 0x1 |

Table 23-1236. High-Speed Multiport USB Host Subsystem Global Initialization (continued)

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------------------------------------------|---------------------------------------------|--------------|
| Wait until reset is finished. | HCOCPSYS [1] SOFT_RESET | 0x0 |
| Enable IRQ event for the FSUSB host controller. | HCINTERRUPTENABLE [31] MIE | 0x1 |
| Enable IRQ event for each function of the FSUSB host controller. | HCINTERRUPTENABLE [6:0] xxx | 0x1 |

| 31:21 | RESERVED | Reserved | R | 0x000 |
| 20 | PRSC | Port 1 reset status change This bit is set when the Port 1 port reset status bit has changed. Write 0x0: No effect Write 0x1: Clears this bit | RW | 0 |
| 19 | OCIC | Port 1 overcurrent indicator change This bit is set when the Port 1 port overcurrent indicator has changed. Write 0x0: No effect Write 0x1: Clears this bit | RW | 0 |
| 18 | PSSC | Port 1 suspend status change This bit is set when the Port1 port suspend status has changed. Write 0x0: No effect Write 0x1: Clears this bit | RW | 0 |
| 17 | PESC | Port 1 enable status change This bit is set when the Port1 port enable status has changed. Write 0x0: No effect Write 0x1: Clears this bit | RW | 0 |
| 16 | CSC | Port 1 connect status change This bit is set when the Port1 port current connect status has changed due to a connect or disconnect event. If current connect status is 0 when a set port reset, set port enable, or set port suspend write occurs, this bit is set. Write 0x0: No effect Write 0x1: Clears this bit Note: If the DR bit HCRHDESCRIPTORB[1] is set, this bit is set only after a root hub reset to inform the system that the device is attached. | RW | 0 |
| 15:10 | RESERVED | Reserved | R | 0x00 |
| 9 | LSDA_CPP | Port 1 low-speed device attached/clear port power. This bit is valid only when port 1 current connect status is 1. Read 0x0: A full-speed device is attached to port 1. Read 0x1: A low-speed device is attached to port 1. Write 0x0: No effect Write 0x1: Clears the port 1 port power status. | RW | 0 |
| 8 | PPS_SPP | Port 1 port power status/set port power. Read 0x0: Port 1 power is off. Read 0x1: Port 1 power is on. Write 0x0: No effect Write 0x1: Sets the port 1 port power status bit | RW | 0 |
| 7:5 | RESERVED | Reserved | R | 0x0 |
| 4 | PRS_SPR | Port 1 port reset status/set port reset. Read 0x0: USB reset is not being sent to port 1. Read 0x1: Port 1 is signaling the USB reset. Write 0x0: No effect Write 0x1: Sets the port 1 port reset status bit and causes the USB host controller to begin signaling USB reset to port 1 | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 3 | POCI_CSS | Port 1 port overcurrent indicator/clear suspend status Read 0x0: No port 1 port overcurrent condition has occurred. Read 0x1: A port 1 port overcurrent condition has occurred. Write 0x0: No effect Write 0x1: When port 1 port suspend status is 1, it causes resume signaling on port 1. When port 1 port suspend status is 0, it has no effect. | RW | 0 |
| 2 | PSS_SPS | Port 1 port suspend status/set port suspend This bit is cleared automatically at the end of the USB resume sequence and also at the end of the USB reset sequence. Write 0x0: No effect Read 0x0: Port 1 is not in the USB suspend state. Read 0x1: Port 1 is in the USB suspend state or is in the resume sequence. Write 0x1: If port 1 current connect status is 1, sets the port 1 port suspend status bit and places port 1 in USB suspend state. If current connect status is 0, it sets connect status instead change to inform the USB host controller driver in an attempt to suspend a disconnected port. | RW | 0 |
| 1 | PES_SPE | Port 1 port enable status/set port enable This bit is automatically set at completion of port 1 USB reset, if it was not already set before the USB reset completed, and is automatically set at the end of a USB suspend, if the port was not enabled when the USB resume completed. Read 0x0: Port 1 is not enabled. Read 0x1: Port 1 is enabled. Write 0x0: No effect Write 0x1: When port 1 current connect status is 1, sets the port 1 port enable status bit. When port 1 current status is 0, it has no effect. | RW | 0 |
| 0 | CCS_CPE | Port 1 current connection status/clear port enable Read 0x0: No USB device is attached to port 1. Read 0x1: Port 1 currently has a USB device attached. Write 0x0: No effect Write 0x1: Clears the port 1 port enable bit Note: This bit is set to 1 if the DR bit HCRHDESCRIPTORB[1] is set to indicate a nonremovable device on port 1. | RW | 0 |

| 24.1 MMC/SD/SDIO Overview | 5386 |
| 24.2 MMC/SD/SDIO Environment | 5393 |
| 24.3 MMC/SD/SDIO Integration | 5401 |
| 24.4 MMC/SD/SDIO Functional Description | 5404 |
| 24.5 MMC/SD/SDIO Programming Guide | 5433 |
| 24.6 MMC/SD/SDIO Register Manual | 5459 |

24.1 MMC/SD/SDIO Overview

The multimedia card high-speed/SD/SDIO (MMC/SD/SDIO) host controller provides an interface between a local host (LH) such as a microprocessor unit (MPU) or digital signal processor (DSP) and either MMC, SD memory cards, or SDIO cards and handles MMC/SD/SDIO transactions with minimal LH intervention.

Optionally, the controller is connected to the level 3 (L3) interconnect to have a direct access to system memory. It also supports two direct memory access (DMA) slave channels or a DMA master access (in this case, slave DMA channels are deactivated) depending on its integration. These controllers are embedded MMC/SD (eMMC/SD) controllers.

The application interface manages transaction semantics. The MMC/SD/SDIO host controller deals with MMC/SD/SDIO protocol at transmission level, data packing, adding cyclic redundancy checks (CRCs), start/end bit, and checking for syntactical correctness.

The application interface can send every MMC/SD/SDIO command and poll for the status of the adapter or wait for an interrupt request, which is sent back in case of exceptions or to warn of end of operation.

The application interface can read card responses or flag registers. It can also mask individual interrupt sources. All these operations can be performed by reading and writing control registers. The MMC/SD/SDIO host controller also supports two DMA channels.

There are five MMC/SD/SDIO host controllers inside the device:

[Figure 24-1](#) gives an overview of the MMC/SD/SDIO1 controller instance (eMMC/SD).

[Figure 24-2](#) gives an overview of the MMC/SD/SDIO2 controller instance (eMMC/SD).

[Figure 24-3](#) gives an overview of the MMC/SD/SDIO3 through MMC/SD/SDIO5 controller instances.

Figure 24-1. MMC/SD/SDIO1 Overview (where i = 1)

Figure 24-2. MMC/SD/SDIO2 Overview (where i = 2)

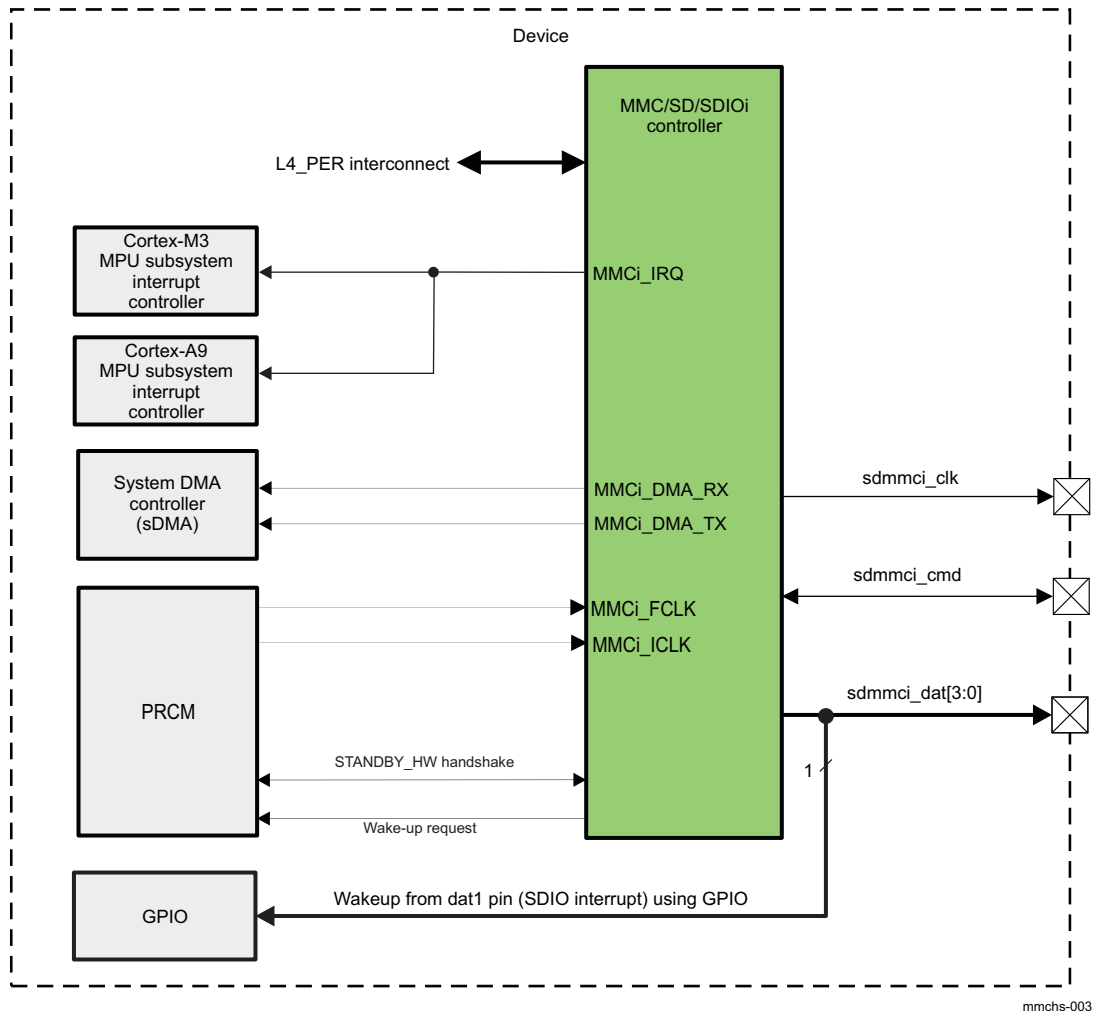

Figure 24-3. MMC/SD/SDIO3 Through MMC/SD/SDIO5 Overview (where i = 3, 4, or 5)

24.1.1 MMC/SD/SDIO Features

This section describes the features supplied by the MMC/SD/SDIO module.

Compliance with standards:

- Full compliance with MMC/eMMC command/response sets as defined in the *JC64 MMC/eMMC Standard Specification v4.41*, including high-capacity (size > 2GB) cards HC MMC
- Full compliance with SD command/response sets as defined in the *SD Specifications Part 1 Physical Layer Simplified Specification*, v3.01, including high-capacity SDXC cards up to 2TB
- Full compliance with SDIO command/response sets and interrupt/read-wait suspend-resume operations, as defined in the *SDIO Card Specification, Part E1*, v2.00
- Full compliance with sets as defined in the *SD Card Specification, Part A2, SD Host Controller Standard Specification*, v2.00
- Full compliance with MMC bus testing procedure as defined in the *Multimedia Card System Specification*, v4.41
- Full compliance with CE-ATA command/response sets as defined in the *CE-ATA Standard Specification*
- Full compliance with ATA for MMCA specification
- Support command completion signal (CCS) and command completion signal disable (CCSD) management as specified in the *CE-ATA Standard Specification*

Main features of the MMC/SD/SDIO host controller:

- Flexible architecture allowing support for new command structure
- Support:
 - 1- or 4-bit transfer mode specifications for SD and SDIO cards
 - 1-, 4-, or 8-bit transfer mode specifications for MMC cards
- Built-in buffer for read or write (up to 2048 bytes in single-buffering, 1024 bytes in double-buffering)
- 32-bit-wide access bus to maximize bus throughput
- Single interrupt line for interrupt source events
- Two slave DMA channels (one for TX, one for RX)
- Designed for low power
- Programmable clock generation
- Support SDIO read wait and suspend/resume functions
- Support stop at block gap
- Support boot mode operations as specified in the *JEDEC JC 64 MMC/eMMC Standard Specification, v4.41*
- Support dual data rate transfers (DDR mode) as specified in *JEDEC JC64 MMC/eMMC Standard Specification, v4.41*
- Support SDA 2.0 Part A2 programming model

Optional features (depending on module integration):

- Master interface (L3 interconnect)
- One master DMA (32-bit ADMA2), replacing the two slave DMA channels
- Retention mode is supported
- Support SDA 2.0 Part A2 DMA feature (ADMA2)

Supported data rates:

- In MMC mode:
 - Up to 768 Mbps (96 MB/s), 8-bit DDR data transfer, with a clock running at 48 MHz
 - Up to 384 Mbps (48 MB/s), 8-bit SDR data transfer, with a clock running at 48 MHz
- In SD mode:
 - Up to 384 Mbps (48 MB/s), 4-bit DDR data transfer with a clock running at 48 MHz
 - Up to 256 Mbps (32 MB/s), 4-bit SDR data transfer with a clock running at 64 MHz
- In SDIO mode:
 - Up to 192 Mbps (24 MB/s) in high-speed mode, 4-bit data transfer with a clock running at 48 MHz
 - Up to 24 Mbps (3 MB/s) in default speed mode, 1-bit data transfer with a clock running at 24 MHz

Supported clock frequencies:

- MMC mode:
 - Up to 48 MHz in DDR and SDR modes
- SD mode:
 - Up to 48 MHz in DDR mode
 - Up to 64 MHz in SDR mode
- SDIO mode:
 - Up to 48 MHz in SDR mode

Known limitations:

- No built-in hardware support for error correction codes (ECCs). For information about ECC, see the *Multimedia Card System Specification, v4.4*, and the *SD Memory Card Specifications, v3.0*.
- The maximum block size defined in the *SD Memory Card Specifications, v3.0*, which the host driver can read and write to the buffer in the host controller, is 2048 bytes. The host controller supports a

maximum block size of 1024 bytes. Up to 512 byte transfers, the buffer in the host controller is considered as a double-buffering with ping-pong management; half of the buffer can be written while the other half is read. For 512 to 1024 byte transfers, the entire buffer is dedicated to the transfer (read only or write only).

- SPI transfers are not supported.
- The module does not support card insertion and removal sensing with pullup resistor on the sdmmc_i_dat3 bus line, as specified in the *SD Memory Card Specifications – Part 1 Physical Layer Specification (SD Group, May 2006)*.

The differences between the MMC/SD/SDIO host controllers and a standard SD host controller defined by the *SD Card Specification, Part A2, SD Host Controller Standard Specification, v2.00* are:

- The MMC/SD/SDIO host controllers support MMC cards.
- The clock divider in the MMC/SD/SDIO host controller supports a wider range of frequency than specified in the *SD Memory Card Specifications, v2.0*. The MMC/SD/SDIO host controller supports odd and even clock ratio.
- The MMC/SD/SDIO host controller supports configurable busy time-out.
- sDMA and ADMA2 64-bit modes are not supported.
- There is no external LED control.

NOTE: Only even ratios are supported in DDR mode.

Table 24-1 lists the features supported in the 4.41 standard.

Table 24-1. Standard 4.41 Supported Features

| Feature | Support | Limitation | Comment |
|-----------------------------------|----------------------------------------------|---------------------------------------------|-------------------------------------------------------------------------------------------------|
| Bus width | 1-bit mode | | x 1, 4, 8 bits |
| | 4-bit mode | | |
| | 8-bit mode | | |
| Support density | No hardware limitation for density support | Limitation can come from file system (32GB) | |
| Simple boot (CMD, alternate boot) | No | | OMAP4 ROM code supports the following boot mode: |
| | | | In raw mode the booting image can be at one of the four consecutive locations in the main area: |
| | | | offset 0x0 |
| | | | 0x20000 (128KB) |
| | | | 0x40000 (256KB) |
| | | | 0x60000 (384KB) |
| | (That is, it supports four boot partitions.) | | |
| Sleep mode | Yes | | |
| Reliable write | Yes | | |
| Secure write protection | Yes | | |
| Hardware reset | No | | Use the reset command instead of GPIO if hardware reset is needed. |
| Secure memory block (RPMB) | Yes | | |
| Partition feature | Yes | | |
| Secure erase | Yes | | |
| 1.2 V | Yes | | |
| DDR Interface (bandwidth) | Up to 96MBps in DDR mode – 8-bit | | |

Table 24-1. Standard 4.41 Supported Features (continued)

| Feature | Support | Limitation | Comment |
|--------------------------------------------|---------|------------|---------|
| High-priority interrupt (read while write) | Yes | | |
| Background operation | Yes | | |
| Enhanced reliable write | Yes | | |

24.2 MMC/SD/SDIO Environment

One MMC/SD/SDIO host controller can support one MMC memory card, one SD memory card, or one SDIO card.

Other combinations (for example, two SD cards, one MMC card, and one SD card) are not supported through a single controller.

- The MMC/SD/SDIO1 controller integrates an internal transceiver that allows a direct connection to the MMC/SD/SDIO card (1.8 V and 3 V), without external transceiver. It is connected to the level 3 (L3) interconnect (internal DMA enabled) and supports 1-, 4-, and 8-bit data transfers.
- The MMC/SD/SDIO2 controller allows connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (JC64, for example). The module is connected to the L3 interconnect (internal DMA enabled) and supports 1-, 4-, and 8-bit data transfers. The second instance also supports an external transceiver and provides direction signals for data and command. Using an external transceiver device precludes 8-bit transfer mode.
- The MMC/SD/SDIO3, MMC/SD/SDIO4, and MMC/SD/SDIO5 controllers allow connecting MMC/SD/SDIO cards (only 1.8V cards) or an external device that uses the MMC/SD/SDIO interface (wireless LAN, for example). The modules are connected to the L4 interconnect and support 1- and 4-bit data transfers.

24.2.1 MMC/SD/SDIO Functional Modes

24.2.1.1 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card

Figure 24-4 shows the MMC/SD/SDIO_i host controller (where *i* = 1 through 5) connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 24-4. MMC/SD/SDIO_i Controller Connected to an MMC, an SD, or an SDIO Card Without External Transceiver (where *i* = 1 through 5)

NOTE: MMC/SD/SDIO1 and MMC/SD/SDIO2 support data transfers on 8 bits (and thus handle data on signals `sdmmci_dat[7:0]`).

Table 24-2 describes the MMC/SD/SDIO_i inputs and outputs.

Table 24-2. MMC/SD/SDIO_i I/O Description Without External Transceiver (where *i* = 1 through 5)

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|-------------------------|--------------------|----------------------------------------------------|----------------------------|
| <code>sdmmci_clk</code> | O | External clock for MMC/SD/SDIO card ⁽³⁾ | 0 |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ hi-Z = High impedance

⁽³⁾ This output signal is also used as retiming input (the `INPUTENABLE` bit in the corresponding pad configuration register must be set to 1).

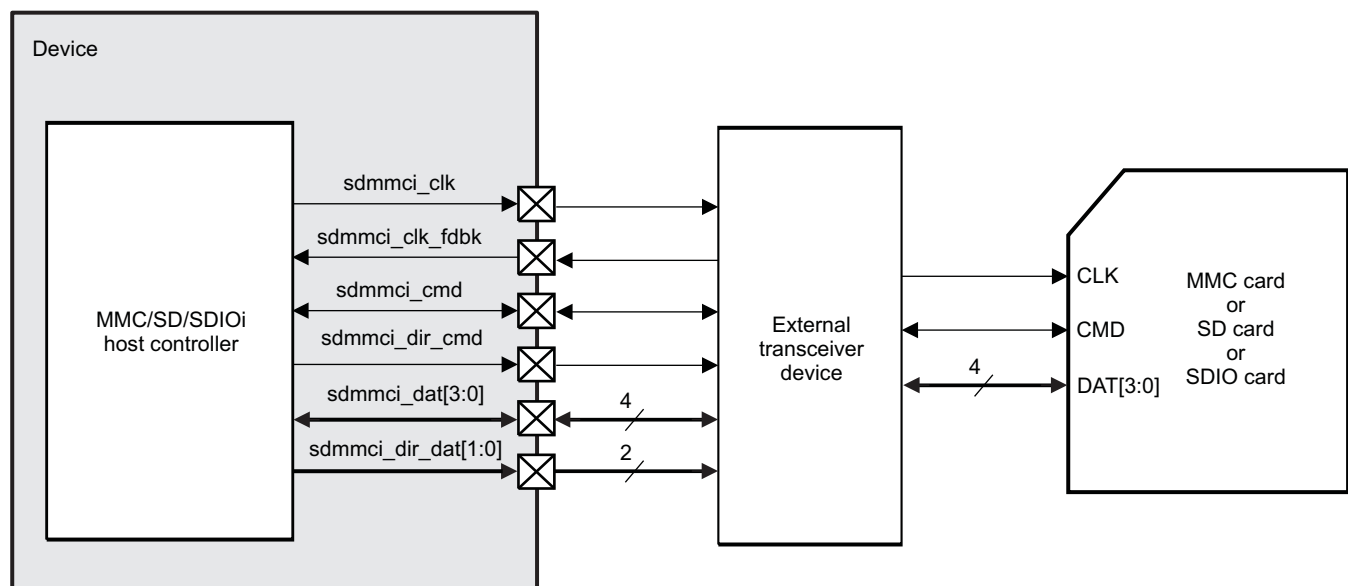

Table 24-2. MMC/SD/SDIOi I/O Description Without External Transceiver (where i = 1 through 5) (continued)

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|------------------|--------------------|---------------------------------------------------------------|----------------------------|
| sdmmc_i_cmd | I/O | Command signal | hi-Z ⁽⁴⁾ |
| sdmmc_i_dat[3:0] | I/O | Data signals | hi-Z ⁽⁴⁾ |
| sdmmc_i_dat[7:4] | I/O | Data signals (only for modules MMC/SD/SDIO1 and MMC/SD/SDIO2) | hi-Z ⁽⁴⁾ |

⁽⁴⁾ Initialized as input upon reset

24.2.1.2 MMC/SD/SDIO Connected to an MMC, an SD, or an SDIO Card Through an External Transceiver Device

Figure 24-5 shows the MMC/SD/SDIOi host controller (where i = 2) connected to an MMC, an SD, or an SDIO card and its related external connections.

Figure 24-5. MMC/SD/SDIOi Controller Connected to an MMC, an SD, or an SDIO Card With External Transceiver (where i = 2)

mmchs-005

Table 24-3 describes the MMC/SD/SDIOi inputs and outputs.

Table 24-3. MMC/SD/SDIOi I/O Description With External Transceiver (where i = 2)

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|------------------|--------------------|--------------------------------------------------------------------------------------------------------------------|----------------------------|
| sdmmc_i_clk | O | External clock for MMC/SD/SDIO card | 0 |
| sdmmc_i_clk_fdbk | I | Input clock from MMC/SD/SDIO card | 0 |
| sdmmc_i_cmd | I/O | Command signal | hi-Z ⁽³⁾ |
| sdmmc_i_dir_cmd | O | Direction control for mmc2_cmd signal when an external transceiver is used (high when transmit, low when receive) | 0 |
| sdmmc_i_dat[3:0] | I/O | Data signals | hi-Z ⁽³⁾ |
| sdmmc_i_dir_dat0 | O | Direction control for mmc2_dat0 signal when an external transceiver is used (high when transmit, low when receive) | 0 |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ hi-Z = High impedance

⁽³⁾ Initialized as input upon reset

Table 24-3. MMC/SD/SDIOi I/O Description With External Transceiver (where i = 2) (continued)

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|----------------|--------------------|--------------------------------------------------------------------------------------------------------------------|----------------------------|
| sdmmc_dir_dat1 | O | Direction control for mmc2_dat1 signal when an external transceiver is used (high when transmit, low when receive) | 0 |

NOTE: There is no signal for individually controlling the sdmmc_dir_dat2 and sdmmc_dir_dat3 direction (sdmmc_dir_dat2 and sdmmc_dir_dat3 are not delivered). This may limit the use of this interface with the SDIO card requesting the wait feature on the sdmmc_dir_dat2 line.

24.2.2 Protocol and Data Format

The bus protocol between the MMC/SD/SDIOi host controller and the card is message-based. Each message is represented by one of the following parts:

Command: A command starts an operation. The command is transferred serially from the MMC/SD/SDIO host controller to the card on the sdmmc_cmd line.

Response: A response is an answer to a command. The response is sent from the card to the MMC/SD/SDIO host controller. It is transferred serially on the sdmmc_cmd line.

Data: Data are transferred from the MMC/SD/SDIOi host controller to the card or from a card to the MMC/SD/SDIO host controller using the data lines.

Busy: The sdmmc_dat0 signal is maintained low by the card as far as it is programming the data received.

CRC status: The CRC result is sent by the card through the sdmmc_dat0 line when executing a write transfer. In the case of transmission error, occurring on any of the active data lines, the card sends a negative CRC status on sdmmc_dat0. In the case of successful transmission, over all active data lines, the card sends a positive CRC status on sdmmc_dat0 and starts the data programming procedure.

24.2.2.1 Protocol

There are two types of data transfer:

- Sequential operation
- Block-oriented operation

There are specific commands for each type of operation (sequential or block-oriented).

For information about commands and programming sequences supported by the MMC, SD, and SDIO cards, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification (Part E1)*.

Figure 24-6 and Figure 24-7 show how sequential operations are defined. Sequential operation is only for 1-bit transfer and initiates a continuous data stream. The transfer terminates when a stop command follows on the sdmmc_cmd line.

CAUTION

Stream commands are supported only by MMC cards.

Figure 24-6. Sequential Read Operation (MMC Cards Only)

Figure 24-7. Sequential Write Operation (MMC Cards Only)

Figure 24-8 and Figure 24-9 show how multiple block-oriented operations are defined. A multiple block-oriented operation sends a data block plus CRC bits. The transfer terminates when a stop command follows on the `sdmmc_cmd` line. These operations are available for all kinds of cards.

Figure 24-8. Multiple Block Read Operation

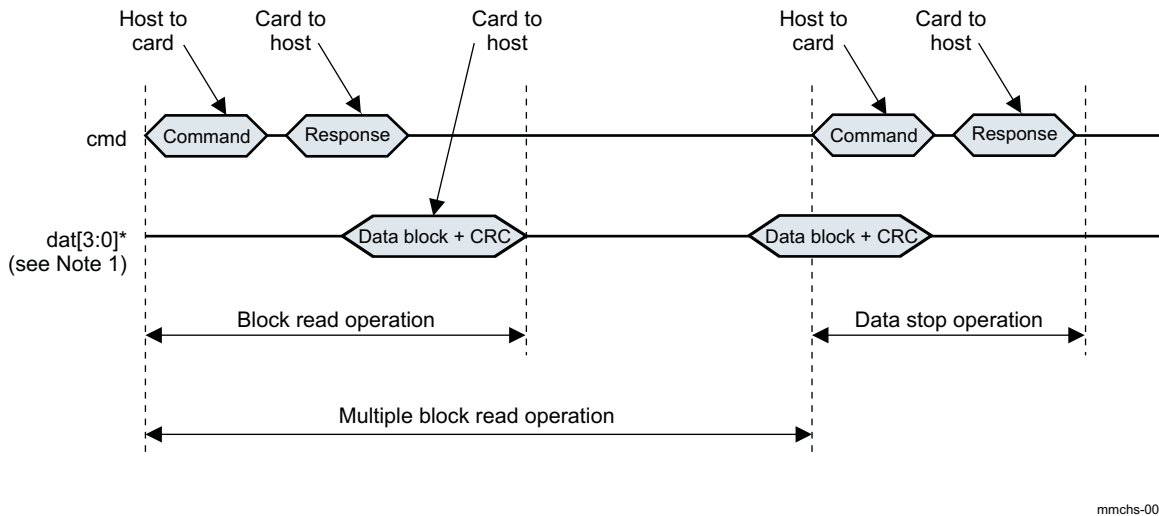

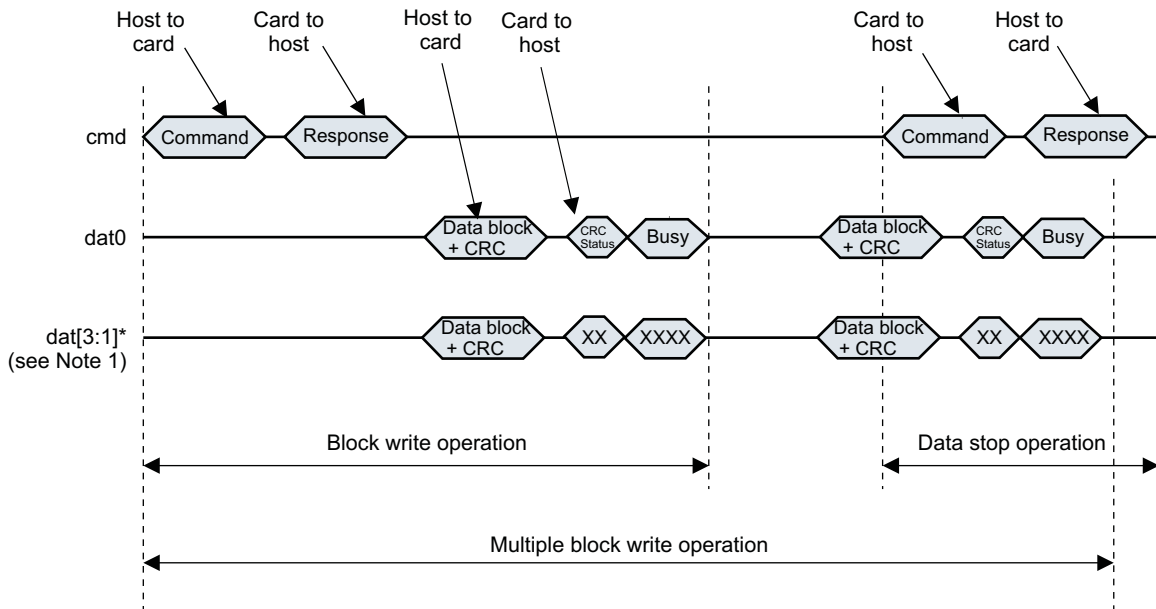

Figure 24-9. Multiple Block Write Operation With Card Busy Signal

mmchs-009

NOTE:

1. The card busy signal is not always generated by the card; the previous examples show a particular case.
2. Software must perform a software reset (set the MMCI.MMCHS_SYSCTL[26] SRD bit to 0x1) after a data time-out to ensure sdmmc_i_clk is stopped.
3. For multiblock transfer, and especially for MMC cards, a transfer can be aborted without using a stop command. If a CMD23 is used before data transfer to define the number of blocks that will be transferred, then the transfer stops automatically after the last block (if the MMC card supports this feature).

24.2.2.2 Data Format

Coding Scheme for Command Token

Command tokens always start with 0 and end with 1. The second bit is a transmitter bit: 1 for a host command. The content is the command index (coded by 6 bits) and an argument (for example, an address), coded by 32 bits. The content is protected by 7-bit CRC checksum (see Figure 24-10).

Figure 24-10. Command Token Format

mmchs-010

Coding Scheme for Response Token

Response tokens always start with 0 and end with 1. The second bit is a transmitter bit: 0 for a card response. The content is different for each type of response (R1, R2, R3, R4, and R5, R6, R7 [for SDIO]) and the content is protected by 7-bit CRC checksum (see [Figure 24-11](#) and [Figure 24-12](#)). Depending on the type of commands sent to the card, the `MMCHS_CMD` register must be configured differently to avoid false CRC or index errors to be flagged on command response (see [Table 24-4](#)). For more information about response types, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification*.

Figure 24-11. Response Token Format (R1, R3, R4, R5, R6, R7)

Figure 24-12. Response Token Format (R2)

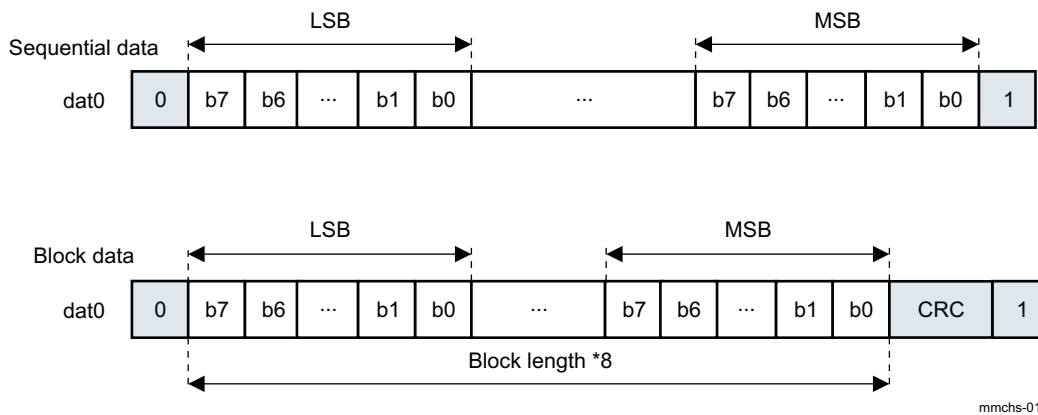

Table 24-4. Relationship Between Configuration and Name of Response Type

| Response Type MMCi.MMCHS_CMD[17:16] RSP_TYPE | Index Check Enable MMCi.MMCHS_CMD[20] CICE | CRC Check Enable MMCi.MMCHS_CMD[19] CCCE | Name of Response Type |
|----------------------------------------------------|--------------------------------------------------|------------------------------------------------|-----------------------|
| 00 | 0 | 0 | No response |
| 01 | 0 | 1 | R2 |
| 10 | 0 | 0 | R3 (R4 for SD cards) |
| 10 | 1 | 1 | R1, R6, R5, R7 |
| 11 | 1 | 1 | R1b, R5b |

Coding Scheme for Data Token

Data tokens always start with 0 and end with 1 (see Figure 24-13 through Figure 24-15).

Figure 24-13. Data Token Format for 1-Bit Transfers

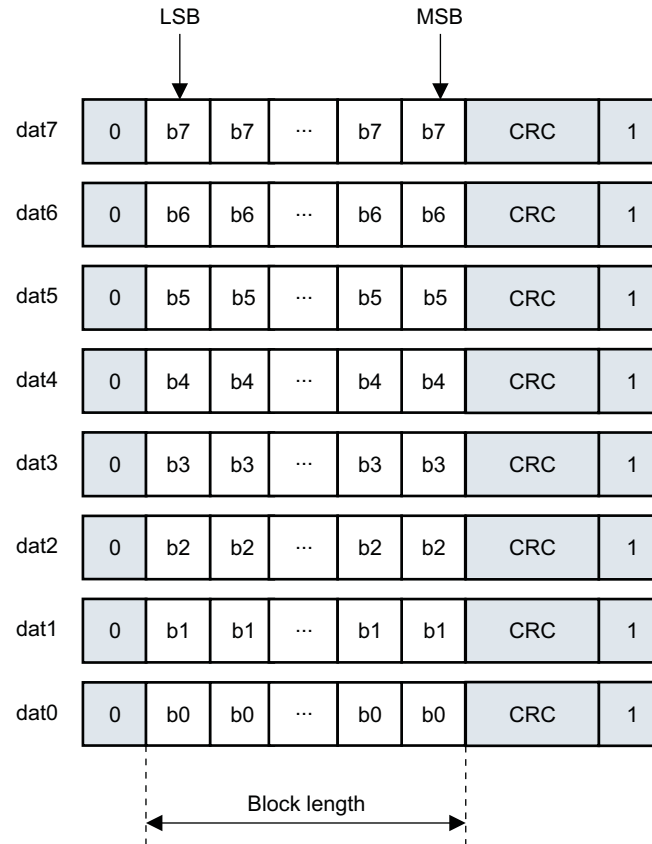

mmchs-013

Figure 24-14. Data Token Format for 4-Bit Transfers

mmchs-014

Figure 24-15. Data Token Format for 8-Bit Transfers

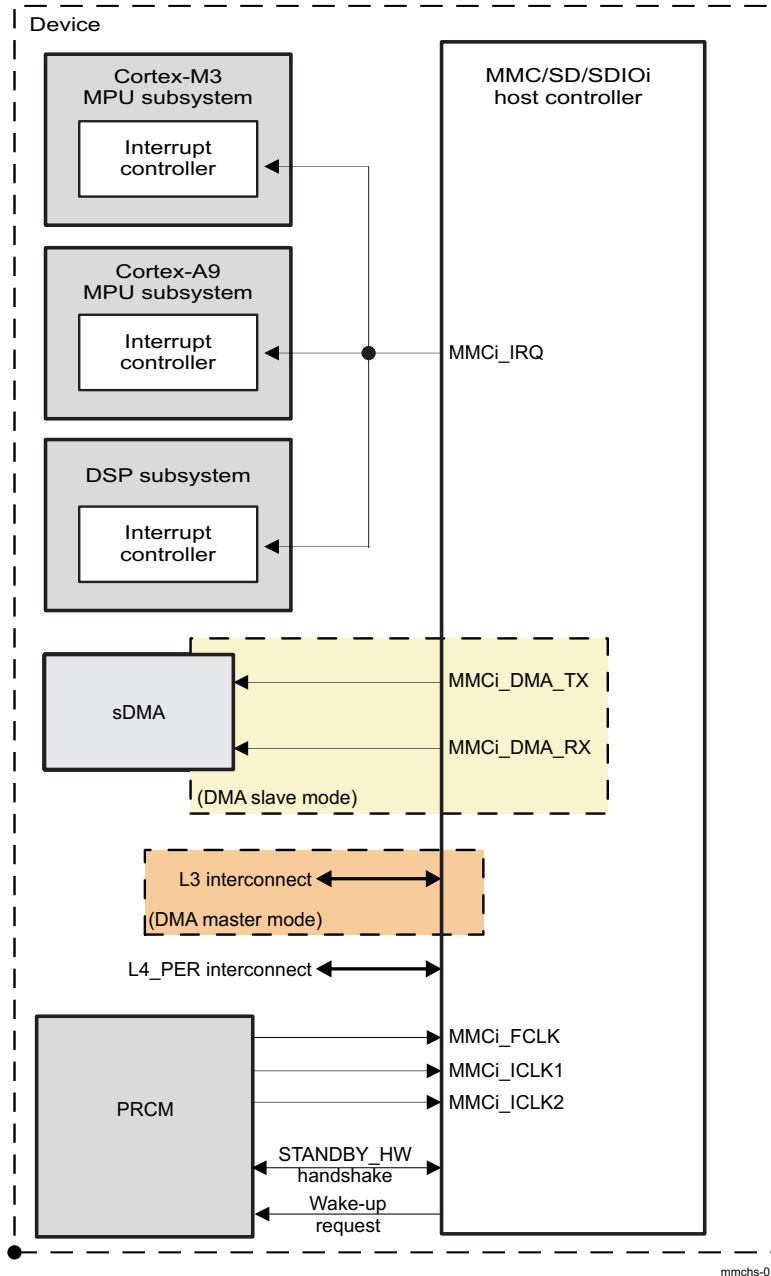

mmchs-015

24.3 MMC/SD/SDIO Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 24-16 shows the MMC/SD/SDIO integration.

Figure 24-16. MMC/SD/SDIO Controllers Integration

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 24-5 through Table 24-7 summarize the integration of the module in the device.

Table 24-5. Integration Attributes

| Module Instance | Attributes | |
|-----------------|--------------|--------------|
| | Power Domain | Interconnect |
| HSMMC1 | PD_L3_INIT | L3 L4_PER |
| HSMMC2 | PD_L3_INIT | L3 L4_PER |
| HSMMC3 | PD_L4_PER | L4_PER |
| HSMMC4 | PD_L4_PER | L4_PER |
| HSMMC5 | PD_L4_PER | L4_PER |

Table 24-6. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|----------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| HSMMC1 | MMC1_FCLK | MMC1_FCLK | PRCM | MMC1 function clock |
| | MMC1_ICLK2 | INIT_L4_ICLK | PRCM | MMC1 interface clock |
| | MMC1_ICLK1 | INIT_L3_ICLK | PRCM | MMC1 interface clock |
| HSMMC2 | MMC2_FCLK | MMC2_FCLK | PRCM | MMC2 function clock |
| | MMC2_ICLK2 | INIT_L4_ICLK | PRCM | MMC2 interface clock |
| | MMC2_ICLK1 | INIT_L3_ICLK | PRCM | MMC2 interface clock |
| HSMMC3 | MMC3_ICLK | PER_L4_ICLK | PRCM | MMC3 interface clock |
| | MMC3_FCLK | PER_48M_FCLK | PRCM | MMC3 function clock |
| HSMMC4 | MMC4_ICLK | PER_L4_ICLK | PRCM | MMC4 interface clock |
| | MMC4_FCLK | PER_48M_FCLK | PRCM | MMC4 function clock |
| HSMMC5 | MMC5_ICLK | PER_L4_ICLK | PRCM | MMC5 interface clock |
| | MMC5_FCLK | PER_48M_FCLK | PRCM | MMC5 function clock |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| HSMMC1 | MMC1_RST | L3_INIT_RET_RST | PRCM | L3 reset to MMC1 |
| HSMMC2 | MMC2_RST | L3_INIT_RET_RST | PRCM | L3 reset to MMC2 |
| HSMMC3 | MMC3_RST | L4_PER_RST | PRCM | L4 reset to MMC3 |
| HSMMC4 | MMC4_RST | L4_PER_RST | PRCM | L4 reset to MMC4 |
| HSMMC5 | MMC5_RST | L4_PER_RST | PRCM | L4 reset to MMC5 |

Table 24-7. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|----------------|-----------------------------|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| HSMMC1 | MMC1_IRQ | MM_IRQ_50 | Cortex-M3 INTC | MMC1 interrupt to Cortex-M3 |
| | MMC1_IRQ | D_IRQ_16 | DSP INTC | MMC1 interrupt to DSP |
| | MMC1_IRQ | MA_IRQ_83 | Cortex-A9 INTC | MMC1 interrupt to Cortex-A9 |
| HSMMC2 | MMC2_IRQ | MM_IRQ_51 | Cortex-M3 INTC | MMC2 interrupt to Cortex-M3 |
| | MMC2_IRQ | D_IRQ_17 | DSP INTC | MMC2 interrupt to DSP |
| | MMC2_IRQ | MA_IRQ_86 | Cortex-A9 INTC | MMC2 interrupt to Cortex-A9 |
| HSMMC3 | MMC3_IRQ | MM_IRQ_52 | Cortex-M3 INTC | MMC3 interrupt to Cortex-M3 |

| HSMMC5 | MMC5_IRQ | MM_IRQ_54 | Cortex-M3 INTC | MMC5 interrupt to Cortex-M3 |
| | MMC5_IRQ | MA_IRQ_59 | Cortex-A9 INTC | MMC5 interrupt to Cortex-A9 |
| DMA Requests | | | | |
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| HSMMC1 | MMC1_DMA_TX | S_DMA_60 | sDMA | MMC1 DMA TX |
| | MMC1_DMA_RX | S_DMA_61 | sDMA | MMC1 DMA RX |
| HSMMC2 | MMC2_DMA_TX | S_DMA_46 | sDMA | MMC2 DMA TX |
| | MMC2_DMA_RX | S_DMA_47 | sDMA | MMC2 DMA RX |
| HSMMC3 | MMC3_DMA_TX | S_DMA_76 | sDMA | MMC3 DMA TX |
| | MMC3_DMA_RX | S_DMA_77 | sDMA | MMC3 DMA RX |
| HSMMC4 | MMC4_DMA_TX | S_DMA_56 | sDMA | MMC4 DMA TX |
| | MMC4_DMA_RX | S_DMA_57 | sDMA | MMC4 DMA RX |
| HSMMC5 | MMC5_DMA_TX | S_DMA_58 | sDMA | MMC5 DMA TX |
| | MMC5_DMA_RX | S_DMA_59 | sDMA | MMC5 DMA RX |

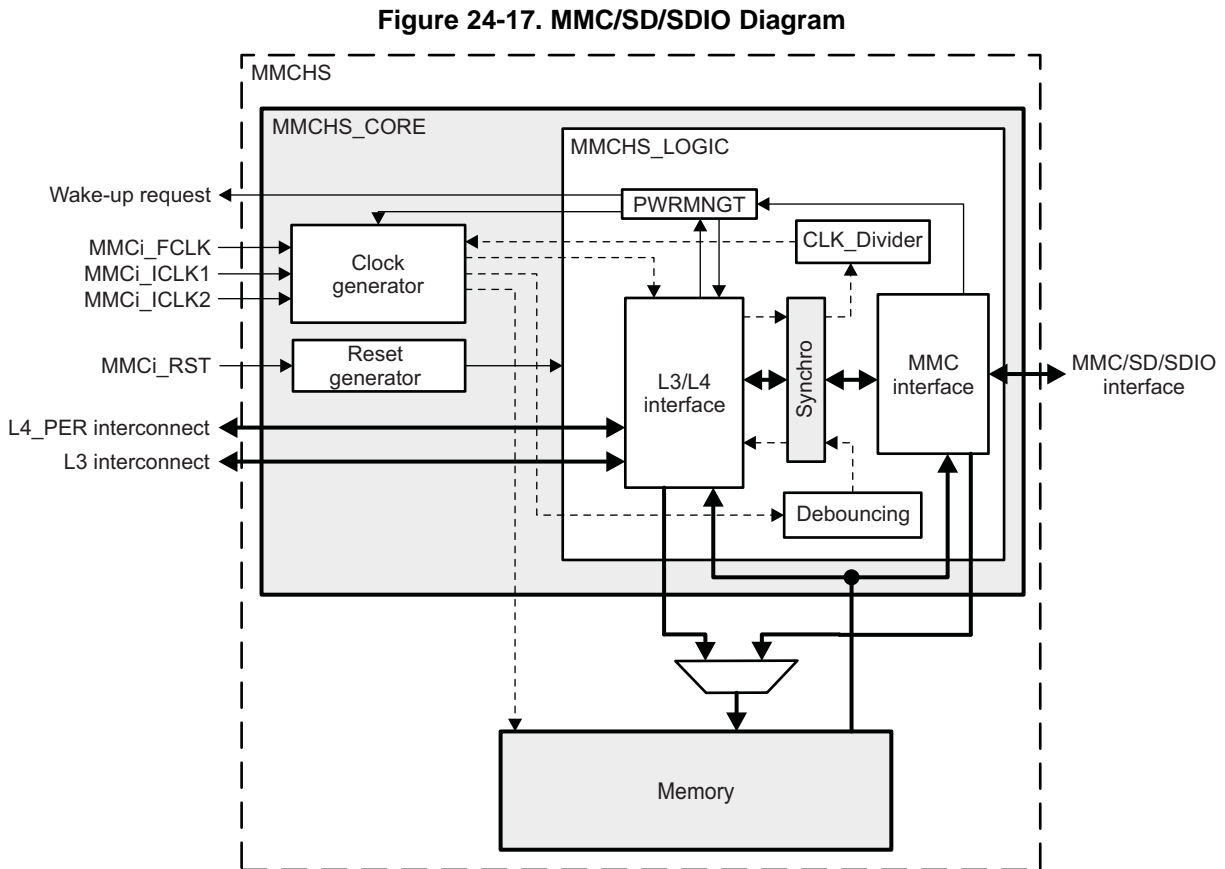

NOTE:

- For a description of the interrupt source, see [Section 24.4.4, Interrupt Requests](#).
- For a description of the DMA source, see [Section 24.4.5, DMA Modes](#).

24.4 MMC/SD/SDIO Functional Description

24.4.1 Block Diagram

Figure 24-17 is a block diagram of the MMC/SD/SDIOi host controller.

mmchs-017

24.4.2 Resets

24.4.2.1 Hardware Reset

The module is reinitialized by the hardware (see [Table 24-6](#) for more information about reset signals).

The MMCHS.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a hardware reset.

NOTE: The functional clock (MMCHS_FCLK) and interface clock (MMCHS_ICLK) must be provided to the module to allow the RESETDONE status bit to be set.

The debounce clock (MMCHS_32K) must be active to reset the module correctly.

This hardware reset signal has a global reset action on the module. All configuration registers and all state-machines are reset in all clock domains.

24.4.2.2 Software Reset

The module is reinitialized by software through the MMCHS.MMCHS_SYSCONFIG[1] SOFTRESET bit. This bit has the same action on the module logic as the hardware signal (MMCHS_RST), with the following exceptions:

- Debounce logic

- MMCi.MMCHS_PSTATE, MMCi.MMCHS_CAPA, and MMCi.MMCHS_CUR_CAPA registers (see the corresponding register description)

The SOFTRESET bit is active high. The bit is automatically reinitialized to 0 by hardware. The MMCi.MMCHS_SYSCTL[24] SRA bit has the same action on the design as the SOFTRESET bit.

The MMCi.MMCHS_SYSSTATUS[0] RESETDONE bit can be monitored by software to check whether the module is ready to use after a software reset.

Moreover, two partial software reset bits are provided:

- MMCi.MMCHS_SYSCTL[26] SRD
- MMCi.MMCHS_SYSCTL[25] SRC

These two reset bits are useful to reinitialize data or command processes, respectively, in case of line conflict. When these bits are set to 1, a reset process is automatically released when the reset completes:

- The MMCi.MMCHS_SYSCTL[26] SRD bit resets all finite state-machines (FSMs) and status management that handle data transfers on the interface and functional sides.
- The MMCi.MMCHS_SYSCTL[25] SRC bit resets all FSMs and status management that handle command transfers on the interface and functional sides.

24.4.3 Power Management

The MMC/SD/SDIO host controller can enter into different modes and save power:

- Normal mode
- Idle mode

The two modes are mutually exclusive (the module can be in normal mode or in idle mode). The MMC/SD/SDIO host controller is compliant with the handshake protocol of the PRCM module.

When the MMC/SD/SDIOi power domain is off, the only way to wake up the power domain and different MMC/SD/SDIOi clocks is to monitor the state of the sdmhci_dat1 input pin through a different GPIO line for each MMC/SD/SDIO interface (for more information, see [Section 25.1](#), *GPIO Overview*, in [Chapter 25](#), *GPIO*).

Normal Mode

The autogating of interface and functional clocks occurs when the following conditions are met:

- The MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 1.
- There is no transaction on the MMC interface.

The autogating of interface and functional clocks stops when the following conditions are met:

- A register access occurs through the L4 interconnect.
- A wake-up event occurs (an interrupt from an SDIO card).
- A transaction on the MMC/SD/SIO interface starts.

Then the MMC/SD/SDIO host controller enters into LOW-POWER state (MMCi_ICLK clock autogated) even if the MMCi.MMCHS_SYSCONFIG[0] AUTOIDLE bit is set to 0.

The functional clock is internally switched off and only interconnect read and write accesses are allowed.

Idle Mode

The MMCi_ICLK and MMCi_FCLK clocks provided to the MMC/SD/SDIO host controller are switched off upon a PRCM module request. They are switched back upon module request.

The MMC/SD/SDIO host controller complies with the handshaking protocol of the PRCM module:

- Idle request from the system power manager
- Idle acknowledgment from the MMC/SD/SDIO host controller
- Wake-up request from the MMC/SD/SDIO host controller

The idle acknowledgment varies according to the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field:

- 0x0: Force-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager

request unconditionally.

- 0x1: No-idle mode. The MMC/SD/SDIO host controller ignores the system power manager request and behaves normally as if the request was not asserted.
- 0x2: Smart-idle mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state.
- 0x3: Smart-idle wake-up-capable mode. The MMC/SD/SDIO host controller acknowledges the system power manager request according to its internal state. However, the module may generate wake-up events when in IDLE state (related to IRQ or DMA requests)

During the smart-idle mode period, the MMC/SD/SDIO host controller acknowledges that the MMCi_ICLK and MMCi_FCLK clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

Transition From Normal Mode to Smart-Idle Mode

Smart-idle mode is enabled when the MMCi.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x2 or 0x3.

The MMC/SD/SDIOi host controller goes into idle mode when the PRCM issues an idle request, according to its internal activity.

The MMC/SD/SDIO host controller acknowledges the idle request from the PRCM after ensuring the following:

- The current multi- or single-block transfer is complete.
- Any interrupt or DMA request is asserted.
- There is no card interrupt on the sdmmc_i_dat1 signal.

As long as the MMC/SD/SDIOi controller does not acknowledge the idle request, if an event occurs, the MMC/SD/SDIOi host controller can still generate an interrupt or a DMA request. In this case, the module ignores the idle request from the PRCM module.

As soon as the MMC/SD/SDIOi controller acknowledges the idle request from the PRCM module:

- If smart-idle mode: The module does not assert any new interrupt or DMA request.
- If smart-idle wake-up-capable mode: The module may generate wake-up events related to an interrupt or DMA request.

Wake-Up Event in Smart-Idle Mode

The wake-up feature is enabled when the following enable wake-up bits are set:

- The MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP bit is set to 0x1.
- The MMCi.MMCHS_HCTL[24] IWE bit is set to 0x1.
- The MMCi.MMCHS_IE[8] CIRQ_ENABLE bit is set to 0x1.

The wakeup is generated only in smart-idle mode, when the module is in idle mode.

Table 24-8 lists the supported cases in smart-idle mode.

Table 24-8. Smart-Idle Mode and Wake-Up Capabilities

| Mode | MMCi_ICLK Clock | MMCi_FCLK Clock | Wake-Up Event |
|----------------|------------------------------------|------------------------------------|------------------------------------------------------------------------------------------------------------|
| Card interrupt | May be switched off ⁽¹⁾ | May be switched off ⁽¹⁾ | The module sends an asynchronous wake-up request when a card interrupt on sdmmc_i_dat1 signal is detected. |

⁽¹⁾ The MMC/SD/SDIOi host controller assumes that both clocks may be switched off, regardless of the value set in the MMCi.MMCHS_SYSCONFIG[9:8] CLOCKACTIVITY bit field.

Transition From Smart-Idle Mode to Normal Mode

The MMC/SD/SDIO host controller detects the end of the idle period when the PRCM module deasserts the idle request.

For the wake-up event, there is a corresponding interrupt status in the MMCI.MMCHS_STAT register. The MMC/SD/SDIOi host controller operates the conversion between the wake-up and interrupt (or DMA request) upon exit from smart-idle mode, if the associated enable bit is set in the MMCI.MMCHS_ISE register.

Interrupts and wake-up events have independent enable and disable controls, accessible through the MMCI.MMCHS_HCTL and MMCI.MMCHS_ISE registers. The overall consistency must be ensured by software.

The interrupt status register MMCI.MMCHS_STAT is updated in the CIRQ bit with the event that caused the wakeup when the MMCI.MMCHS_IE[8] CIRQ_ENABLE associated bit is enabled.

Then, the wake-up event at the origin of the transition from smart-idle mode to normal mode is converted into its corresponding interrupt or DMA request. (The MMCI.MMCHS_STAT register is updated and the status of the interrupt signal changes.)

When the idle request from the PRCM module is deasserted, the module switches back to normal mode. The module is fully operational.

Force-Idle Mode

Force-idle mode is enabled when the MMCI.MMCHS_SYSCONFIG[4:3] SIDLEMODE bit field is set to 0x0.

Force-idle mode is an idle mode in which the MMC/SD/SDIOi host controller responds unconditionally to the idle request from the PRCM module. Moreover, in this mode, the MMC/SD/SDIOi host controller unconditionally deasserts interrupts and DMA request lines asserted.

The transition from normal mode to force-idle mode does not affect the bits of the MMCI.MMCHS_STAT register.

In force-idle mode, the interrupt and DMA request lines are deasserted. MMCI_ICLK and MMCI_FCLK can be switched off.

CAUTION

In force-idle mode, an idle request from the PRCM module during a command or a data transfer can lead to an unexpected and unpredictable result. When the module is idle, any access to the module generates an error as long as the MMCI_ICLK clock is alive.

The module exits force-idle mode when the PRCM module deasserts the idle request. Then the module switches back to normal mode. The module is fully operational. Interrupt and DMA request lines are optionally asserted one clock cycle later.

Local Power Management

Table 24-9 describes the power-management features available for the MMC/SD/SDIOi modules.

NOTE: For information about source clock gating and a description of the sleep/wake-up transitions, see Section 3.1.1.1, *Clock Management*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 24-9. Local Power-Management Features

| Feature | Registers | Description |
|-------------------|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Clock auto gating | MMCHS_SYSCONFIG[0] AUTOIDLE | This bit allows a local power optimization inside the module by gating the MMCI_ICLK clock upon the interface activity, or gating the MMCI_FCLK clock upon the internal activity. |

Table 24-9. Local Power-Management Features (continued)

| Feature | Registers | Description |
|------------------------|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| Slave idle modes | MMCHS_SYSCONFIG [3:4] SIDLEMODE | Force-idle, no-idle, and smart-idle modes are available. |
| Clock activity | MMCHS_SYSCONFIG [8:9] CLOCKACTIVITY | For configuration details, see Table 24-10 . |
| Master standby modes | MMCHS_SYSCONFIG [12:13] STANDBYMODE | Force-idle, no-idle, and smart-idle modes are available. |
| Global wake-up enable | MMCHS_SYSCONFIG [2] ENAWAKEUP | This bit enables the wake-up feature at the module level. |
| Wake-up sources enable | MMCHS_HCTL register | This register holds one active-high enable bit per event source that is able to generate a wake-up signal. |

Table 24-10. Clock Activity Settings

| CLOCKACTIVITY Values | Clock State When Module is in IDLE State | | Features Available When Module is in IDLE State | Wake-Up Events |
|----------------------|------------------------------------------|-----------|-------------------------------------------------|----------------|
| | MMCi_ICLK | MMCi_FCLK | | |
| 00 | OFF | OFF | None | Card interrupt |
| 10 | OFF | ON | None | |
| 01 | ON | OFF | None | |
| 11 | ON | ON | All | |

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the CLOCKACTIVITY and MMCi clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

24.4.4 Interrupt Requests

Several internal module events can generate an interrupt. Each interrupt has a status bit, an interrupt enable bit, and a signal status enable:

- The status of each type of interrupt is automatically updated in the [MMCi.MMCHS_STAT](#) register; it indicates which service is required.
- The interrupt status enable bits of the [MMCi.MMCHS_IE](#) register enable or disable the automatic update of the [MMCi.MMCHS_STAT](#) register on an event-by-event basis.
- The interrupt signal enable bits of the [MMCi.MMCHS_ISE](#) register enable or disable the transmission of an interrupt request on the interrupt line [MMCi_IRQ](#) (from the MMC/SD/SDIOi host controller to the MPU subsystem INTC) on an event-by-event basis.

If an interrupt status is disabled in the [MMCi.MMCHS_IE](#) register, then the corresponding interrupt request is not transmitted, and the value of the corresponding interrupt signal enable in the [MMCi.MMCHS_ISE](#) register is ignored.

When an interrupt event occurs, the corresponding status bit is automatically set to 0x1 (the MMC/SD/SDIOi host controller updates the status bit) in the [MMCi.MMCHS_STAT](#) register. If a mask is later applied on the interrupt in the [MMCi.MMCHS_ISE](#) register, the interrupt request is deactivated.

When the interrupt source has not been serviced, if the interrupt status is cleared in the [MMCi.MMCHS_STAT](#) register and the corresponding mask is removed from the [MMCi.MMCHS_ISE](#) register, the interrupt status is not asserted again in the [MMCi.MMCHS_STAT](#) register and the MMC/SD/SDIOi host controller does not transmit an interrupt request.

CAUTION

If the buffer write ready (BWR) interrupt or the buffer read ready (BRR) only interrupt are not serviced and are cleared in the MMCi.MMCHS_STAT register, and the corresponding mask is removed, then the MMC/SD/SDIOi host controller waits for the service of the interrupt without updating the status MMCi.MMCHS_STAT register or transmitting an interrupt request.

Table 24-11 lists the event flags, and their mask, that can cause module interrupts.

Table 24-11. Events

| Event Flag | Event Mask | Map to | Description |
|----------------------|------------------------------|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MMCHS_STAT[29] BADA | MMCHS_IE[29] BADA_ENABLE | MMCi_IRQ | <p>Bad access to data space. This bit is set automatically to indicate a bad access to buffer when not allowed:</p> <p>This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE[11] BRE = 0).</p> <p>This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_STATE[10] BWE = 0).</p> |
| MMCHS_STAT[28] CERR | MMCHS_IE[28] CERR_ENABLE | MMCi_IRQ | <p>Card error. This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5, or R5b. Only bits referenced as type E (error) in the status field in the response can set a card status error. An error bit in the response is flagged only if the corresponding bit in the card status response error MMCHS_CSRE is set. There is no card error detection for the auto CMD12 command.</p> |
| MMCHS_STAT[25] ADMAE | MMCHS_IE[25] ADMAE_ENABLE | MMCi_IRQ | <p>ADMA error. This bit is set when the host controller detects errors during an ADMA-based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA error status register. In addition, the host controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state.</p> |
| MMCHS_STAT[24] ACE | MMCHS_IE[24] ACE_ENABLE | MMCi_IRQ | <p>Auto CMD12 error. This bit is set automatically when one bit in the auto CMD12 error status register changes from 0 to 1.</p> |
| MMCHS_STAT[22] DEB | MMCHS_IE[22] DEB_ENABLE | MMCi_IRQ | <p>Data end bit error. This bit is set automatically when detecting a 0 at the end bit position of read data on the DAT line or at the end position of the CRC status in write mode.</p> |
| MMCHS_STAT[21] DCRC | MMCHS_IE[21] DCRC_ENABLE | MMCi_IRQ | <p>Data CRC error. This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status difference of a position 010 token during a block write command.</p> |
| MMCHS_STAT[20] DTO | MMCHS_IE[20] DTO_ENABLE | MMCi_IRQ | <p>Data time-out error. This bit is set automatically according to the following conditions:</p> <ul style="list-style-type: none"> – Busy time-out for R1b, R5b response type – Busy time-out after write CRC status – Write CRC status time-out – Read data time-out |
| MMCHS_STAT[19] CIE | MMCHS_IE[19] CIE_ENABLE | MMCi_IRQ | <p>Command index error. This bit is set automatically when the response index differs from the corresponding command index previously emitted. The check is enabled through the MMCHS_CMD[20] CICE bit.</p> |

Table 24-11. Events (continued)

| Event Flag | Event Mask | Map to | Description |
|-------------------------------------|---------------------------------------------|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MMCHS_STAT[18] CEB | MMCHS_IE[18] CEB_ENABLE | MMCi_IRQ | Command end bit error. This bit is set automatically when detecting a 0 at the end bit position of a command response. |
| MMCHS_STAT[17] CCRC | MMCHS_IE[17] CCRC_ENABLE | MMCi_IRQ | Command CRC error. This bit is set automatically when there is a CRC7 error in the command response. CRC check is enabled through the MMCHS_CMD[19] CCCE bit. |
| MMCHS_STAT[16] CTO | MMCHS_IE[16] CTO_ENABLE | MMCi_IRQ | Command time-out error. This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within five clock cycles, the time-out is still detected at 64 clock cycles. |
| MMCHS_STAT[15] ERRI | MMCHS_IE[15] ERRI_ENABLE | MMCi_IRQ | Error interrupt. If any of the bits in the error interrupt status register (MMCHS_STAT[24:15]) are set, this bit is set to 1. |
| MMCHS_STAT[10] BSR | MMCHS_IE[10] BSR_ENABLE | MMCi_IRQ | Boot status received interrupt. This bit is set automatically when the MMCHS_CON[18] BOOT_CF0 bit is set to 0x1 or 0x2 and a boot status is received on the dat0 line. This interrupt is useful only for the MMC card. |
| MMCHS_STAT[8] CIRQ | MMCHS_IE[8] CIRQ_ENABLE | MMCi_IRQ | Card interrupt. This bit is used only for SD, SDIO, and CE-ATA cards. In 1-bit mode, the interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, the interrupt source is sampled during the interrupt cycle. In CE-ATA mode, the interrupt source is detected when the card drives the CMD line to 0 during one cycle after data transmission end. |
| MMCHS_STAT[5] BRR | MMCHS_IE[5] BRR_ENABLE | MMCi_IRQ | Buffer read ready. This bit is set automatically during a read operation to the card (see class 2 block-oriented read commands) when one block specified by the MMCHS_BLK[10:0] BLEN bit field is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the LH needs to empty the buffer by reading it. |
| MMCHS_STAT[4] BWR | MMCHS_IE[4] BWR_ENABLE | MMCi_IRQ | Buffer write ready. This bit is set automatically during a write operation to the card (see class 4 block-oriented write command) when the host can write a complete block as specified by the MMCHS_BLK[10:0] BLEN bit field. It indicates that the memory card has emptied one block from the buffer and that the LH can write one block of data into the buffer. |
| MMCHS_STAT[3] DMA | MMCHS_IE[3] DMA_ENABLE | MMCi_IRQ | DMA interrupt. This status is set when an interrupt is required in the ADMA instruction and after the data transfer completes. |
| MMCHS_STAT[2] BGE | MMCHS_IE[2] BGE_ENABLE | MMCi_IRQ | Block gap event. When a stop at the block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation. |
| MMCHS_STAT[1] TC | MMCHS_IE[1] TC_ENABLE | MMCi_IRQ | Transfer completed. This bit is always set when a read/write transfer is complete or between two blocks when the transfer is stopped because of a stop at block gap request (MMCHS_HCTL[16] SBGR). – In read mode: This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[9] RTA). |

Table 24-11. Events (continued)

| Event Flag | Event Mask | Map to | Description |
|----------------------------------|---------------------------------------|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MMCHS_STAT[0] CC | MMCHS_IE[0] CC_ENABLE | MMCi_IRQ | <p>– In write mode: This bit is automatically set on completion of the DAT line use (MMCHS_PSTATE[2] DLA).</p> <p>Command complete. This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI). If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command. A command time-out error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC). If a response is expected but none is received, then a command time-out error is detected and signaled, instead of the command complete interrupt.</p> |

NOTE: To send an interrupt request to the MMCi_IRQ line, the mask/unmask bit must be set in the MMCi.[MMCHS_IE](#) and MMCi.[MMCHS_ISE](#) registers.

The MMC/SD/SDIOi host controller supports interrupt-driven operation and polling.

24.4.4.1 Interrupt-Driven Operation

An interrupt enable bit must be set in the MMCi.[MMCHS_IE](#) register to enable the module internal source of interrupt.

When an interrupt event occurs, the single interrupt line is asserted and the LH must:

1. Read the MMCi.[MMCHS_STAT](#) register to identify which event occurred.
2. Write 1 into the corresponding bit of the MMCi.[MMCHS_STAT](#) register to clear the interrupt status and release the interrupt line (if a read is done after this write, this returns 0).

NOTE: In the MMCi.[MMCHS_STAT](#) register, the card interrupt (CIRQ) and error interrupt (ERRI) bits cannot be cleared.

The MMCi.[MMCHS_STAT\[8\]](#) CIRQ status bit must be masked by disabling the MMCi.[MMCHS_IE\[8\]](#) CIRQ_ENABLE bit (set to 0x0), and then the interrupt routine must clear the SDIO interrupt source in the SDIO card common control register (CCCR).

The MMCi.[MMCHS_STAT\[15\]](#) ERRI bit is automatically cleared when all status bits in the MMCi.[MMCHS_STAT\[31:16\]](#) bit field are cleared.

24.4.4.2 Polling

When the interrupt capability of an event is disabled in the MMCi.[MMCHS_ISE](#) register, the interrupt line is not asserted:

- Software can poll the status bit in the MMCi.[MMCHS_STAT](#) register to detect when the corresponding event occurs.
- Writing 1 into the corresponding bit of the MMCi.[MMCHS_STAT](#) register clears the interrupt status and does not affect the interrupt line state.

NOTE: Refer to the previous note concerning clearing of the CIRQ and ERRI bits.

24.4.5 DMA Modes

Two DMA managements can be used to load data from memory to the internal buffer of the controller (or vice versa). These modes are exclusive and depend on the module integration.

- DMA master mode

DMA master mode is selected by setting the [MMCHS_CON\[20\] DMA_MNS](#) bit to 1. In this case, the controller has direct access to data using a specific algorithm called ADMA2 (prevents the system from being interrupted). Data are exchanged using the L3 master interface, which supports burst accesses to maximize throughput.

NOTE: This mode is supported only by modules connected to the L3 interconnect. See [Section 24.1, MMC/SD/SDIO Overview](#), for more information and/or check the value of the [MMCHS_HL_HWINFO\[0\] MADMA_EN](#) bit.

This mode is available for modules MMC1 and MMC2.

- DMA slave mode

DMA slave mode is selected by setting the [MMCHS_CON\[20\] DMA_MNS](#) bit to 0. In this case, the controller is slave on the DMA transaction managed by two separated requests (MMCi_DMA_TX and MMcI_DMA_RX).

NOTE: This mode is the only mode supported by modules that are not connected to the L3 interconnect (regardless of the value of the [MMCHS_CON\[20\] DMA_MNS](#) bit). See [Section 24.1, MMC/SD/SDIO Overview](#), for more information and/or to check the value of the [MMCHS_HL_HWINFO\[0\] MADMA_EN](#) bit.

This mode is available for all MMC modules.

24.4.5.1 Master DMA Operations

The MMC/SD/SDIOi host controller has direct access to the internal data. This feature is called advanced DMA (ADMA). It follows a specific algorithm (ADMA2) defined by an instruction in memory that starts at an address previously loaded in the [MMCHS_ADMASAL](#) register before any data command issued to the MMC card. Only 32-bit address spacing is supported by the controller for data storage.

NOTE: This mode is supported only by modules connected to the L3 interconnect. See [Section 24.1, MMC/SD/SDIO Overview](#), for more information and/or to check the value of the [MMCHS_HL_HWINFO\[0\] MADMA_EN](#) bit.

These instructions must be loaded by software in a 32-bit-addressed descriptor table in system memory, as shown in [Figure 24-18](#). In this case the [MMCHS_ADMASAL](#) register is used as the program address pointer

Figure 24-18. ADMA Block Diagram Overview

mmchs-018

24.4.5.1.1 Descriptor Table Description

Each descriptor line contains an address, a length, and attributes fields. The attributes define which operation will be processed. Every descriptor line is a 64-bit-wide register that is fetched in the controller using the L3 master interface, and requires two 32-bit accesses to memory.

Table 24-12 shows the structure of a descriptor line.

Table 24-12. Descriptor Line Overview

| Address Field | | Length | | Reserved | | Attributes | | | | | |
|----------------|----|---------------|----|----------|---|------------|------|---|-----|-----|-------|
| 63 | 32 | 31 | 16 | 15 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| 32-bit Address | | 16-bit Length | | 0x0 | | Act2 | Act1 | 0 | Int | Ent | Valid |

The attribute of the descriptor line is divided into two parts:

- Attributes[5:4]: The action to be processed by the ADMA engine
- Attributes[3:0]: Additional parameters characterizing the behavior of the ADMA engine

Table 24-13 describes the available actions of a descriptor line.

Table 24-13. Available Actions of a Descriptor Line

| Act2 | Act1 | Symbol | Comment | Operation |
|------|------|--------|-----------------|----------------------------------------------------------|
| 0 | 0 | Nop | No operation | Do not execute the current line and go to the next line. |
| 0 | 1 | Rsv | Reserved | Reserved action. Behaves the same as the Nop command. |
| 1 | 0 | Tran | Transfer data | Transfer data of one descriptor line. |
| 1 | 1 | Link | Link descriptor | Link to another descriptor. |

Table 24-14 describes the additional parameters of a descriptor line.

Table 24-14. Additional Parameters of a Descriptor Line

| Bit | Description |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Valid | Valid = 1 indicates that this descriptor line is effective. If Valid = 0, an ADMA error interrupt is generated and the ADMA is stopped. This prevents runaways. |
| End | End = 1 indicates the end of a descriptor. The transfer-complete interrupt is generated when the operation of the descriptor line is complete. |
| Int | Int = 1 generates a DMA interrupt when the operation of the descriptor line is complete. |

24.4.5.1.2 Requirements for Descriptors

The following sections discuss restrictions and tips on how to correctly configure the descriptors to be used by the ADMA engine.

24.4.5.1.2.1 Data Length

There are three requirements to program descriptors:

- The minimum unit of address is 4 bytes.
- The maximum data length of each descriptor line is less than 64KB.
- Total length = Length₁ + Length₂ + Length₃ + ... + Length_n must be a multiple of the block size.

If the total length of a descriptor is not a multiple of the block size, data transfer with the ADMA engine may not have been terminated. In this case, the controller returns a data time-out event and the transfer is aborted.

The block count register (the `MMCHS_BLK[31:16]` NBLK bit field) is defined as 16 bits and limits data transfers to a maximum of 65,535 blocks. If the ADMA data transfer size is less than or equal to the 65,535-block transfer, the block count register can be used. In this case, the total length of the descriptor table must be equivalent to "block size" by "block count." If the ADMA data transfer is greater than 65,535 blocks, the block count register must be disabled by setting the block count enable bit (the `MMCHS_CMD[1]` BCE bit) to 0. In this case, the length of the data transfer is not designated by the block count but by the descriptor table.

NOTE: The timing for detecting the last block on the SD bus may differ, which affects control of the read transfer active (`MMCHS_PSTATE[9]` RTA), write transfer active (`MMCHS_PSTATE[8]` WTA), and DAT line active (`MMCHS_PSTATE[2]` DLA) bits. In case of a read operation, more blocks than required may be read from the card. The host driver must ignore an out-of-range error if the read operation is for the last block of the memory area.

24.4.5.1.2.2 Supported Features

The ADMA engine does not support the suspend/resume function. However, the stop and continue functions are available.

When the stop-at-block-gap-request (the `MMCHS_HCTL[16]` SBGR bit) is set during the ADMA operation, the block gap event interrupt is generated when the ADMA is stopped at block gap (the `MMCHS_STAT[2]` BGE bit). The host controller must stop the ADMA read operation by using read wait or by stopping the SD clock. While stopping ADMA, SD commands cannot be issued.

24.4.5.1.2.3 Error Generation

When an error occurs during an ADMA transfer, the ADMA operation is stopped and the ADMA error interrupt is generated. The ADMA error state field (the MMCHS_ADMAES[1:0] AES bit field) holds the state of the ADMA when it is stopped. Software can identify the erroneous descriptor line by using the following method:

- If ADMA stopped at ST_FDS state, the ADMA system address register (MMCHS_ADMASAL) points to the erroneous descriptor line.
- If ADMA stopped at ST_TFR or ST_STOP state, the ADMA system address register points to the descriptor line following the erroneous one.

24.4.5.1.3 Advanced DMA Description

The ADMA is a DMA controller embedded in each eMMC controller. It can be seen as a small sequencer that fetches a descriptor line and executes the corresponding action. The base address of the descriptor table is stored in the MMCHS_ADMASAL register.

NOTE: Software must write the base address of the descriptor table in the MMCHS_ADMASAL register before the first use of the ADMA engine.

The ADMA program is executed according to descriptor attributes (see Section 24.4.5.1.1, Descriptor Table Description) and an FSM, as shown in Figure 24-19.

Figure 24-19. ADMA Finite State-Machine

mmchs-019

Table 24-15 describes each state of the ADMA FSM.

Table 24-15. ADMA2 States Description

| State Name | Operation |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ST_FDS (fetch descriptor) | ADMA2 fetches a descriptor line and sets parameters in internal registers. It then goes to the ST_CADR state. |
| ST_CADR (change address) | Link operation loads another descriptor address to the ADMA system address register (MMCHS_ADMASAL). In other operations, the ADMA system address register is incremented to point to the next descriptor line. NOTE: ADMA2 does not stop at this state if some errors occur. |

Table 24-15. ADMA2 States Description (continued)

| State Name | Operation |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ST_TFR (transfer data) | Data transfer of one descriptor line is executed between system memory and the SD card: <ul style="list-style-type: none"> • If data transfer continues (End = 0) go to ST_FDS state. • If data transfer completes, go to ST_STOP state. |
| ST_STOP (stop DMA) | ADMA2 stays in this state in the following cases: <ul style="list-style-type: none"> • After power on reset (POR) or software reset • All descriptor data transfers are complete. If a new ADMA operation is stated by writing the command register, go to ST_FDS state. |

Table 24-16 gives the description of each symbol used in the ADMA FSM state-machine (see Figure 24-19).

Table 24-16. ADMA FSM Symbol Definition

| Symbol | Definition |
|-----------|-----------------------------------|
| SYS_ADR | ADMA system address register |
| SYS_ADR++ | Point to next descriptor line |
| DAT_ADR | Data address register (internal) |
| DAT_LEN | Data length register (internal) |
| TFC | Transfer complete flag (internal) |
| STOP | Stop-at-block-gap request |

24.4.5.2 Slave DMA Operations

The MMC/SD/SDIOi host controller can be interfaced with a DMA controller. At the system level, the advantage is to discharge the LH of the data transfers. The module does not support wide DMA access (above 1024 bytes) for SD cards, as specified in the *SD Card Specification* and *SD Host Controller Standard Specification*.

NOTE: This mode is implied by modules that are not connected to the L3 interconnect (regardless of the value of the `MMCHS_CON[20]` DMA_MNS bit). See Section 24.4.5.1, *Master DMA Operations*, for more information and/or to check the value of the `MMCHS_HL_HWINFO[0]` MADMA_EN bit.

The DMA request is issued if the following conditions are met:

- The `MMCi.MMCHS_CMD[0]` DE bit is set to 1 to trigger the initial DMA request (the write must be done when running the data transfer command).
- A command was emitted on the `sdmmc_i_cmd` line.
- There is enough space in the buffer of the MMC/SD/SDIOi host controller to write an entire block (BLEN writes).

24.4.5.2.1 DMA Receive Mode

In a DMA block read operation (single or multiple), the request signal `MMCi_DMA_RX` is asserted to its active level when a complete block is written in the buffer. The block size transfer is specified in the `MMCi.MMCHS_BLK[10:0]` BLEN bit field.

`MMCi_DMA_RX` is deasserted to its inactive level when the sDMA reads one word from the buffer.

Only one request is sent per block; the DMA controller can make a 1-shot read access or several DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN field block size.

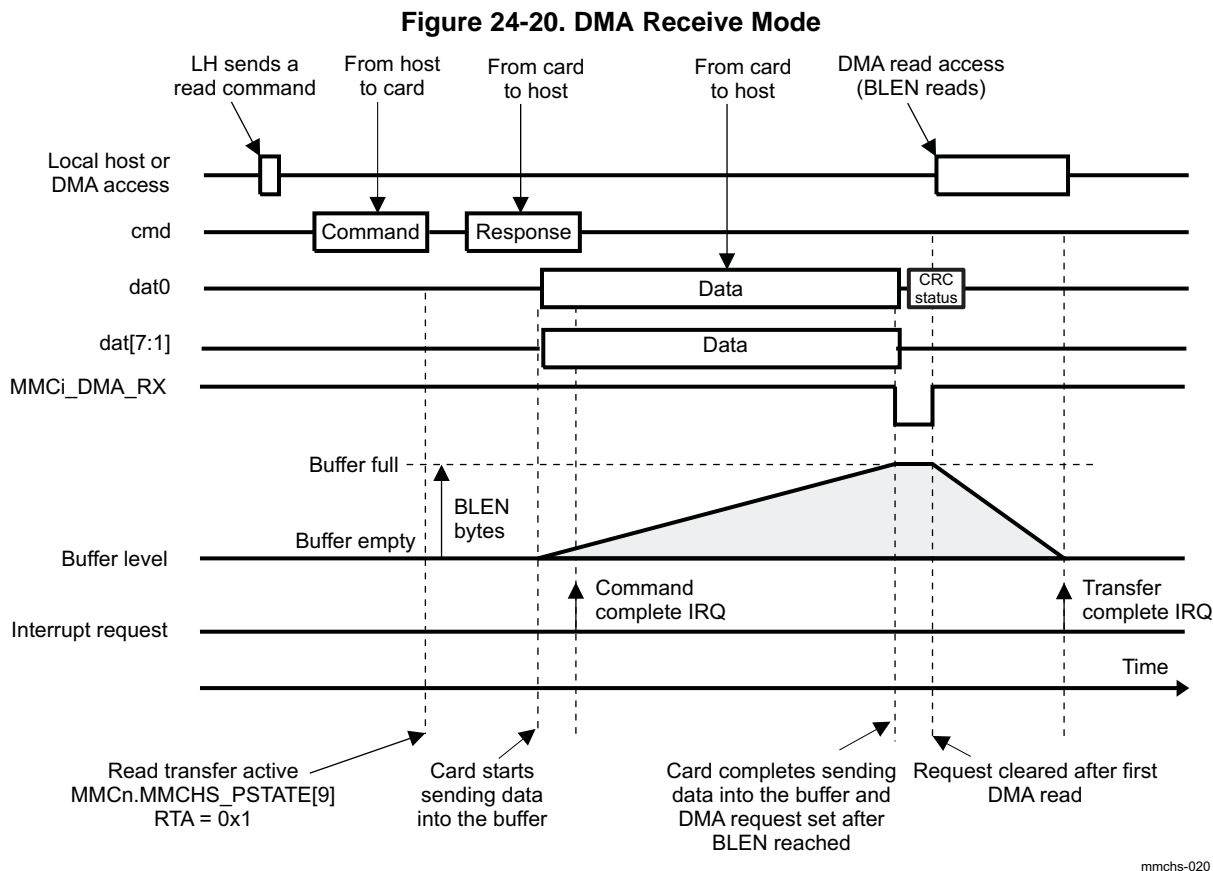

New DMA requests are internally masked if the sDMA has not read exactly BLEN bytes and a new complete block is not ready. Because DMA accesses are 32-bit accesses, the number of sDMA read is $\text{Integer}(\text{BLEN}/4) + 1$.

The receive buffer never overflows. In multiple block transfers for block sizes larger than 512 bytes, when the buffer becomes full, the `sdmmc_i_clk` clock signal (provided to the card) is momentarily stopped until the sDMA or the MPU performs a read access, which reads a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 24-20 shows DMA receive mode.

24.4.5.2.2 DMA Transmit Mode

In a DMA block write operation (single or multiple), the request signal `MMCi_DMA_TX` is asserted to its active level when a complete block is to be written to the buffer. The block size transfer is specified in the `MMCi.MMCHS_BLK[10:0]` BLEN bit field.

`MMCi_DMA_TX` is deasserted to its inactive level when the sDMA writes one word to the buffer.

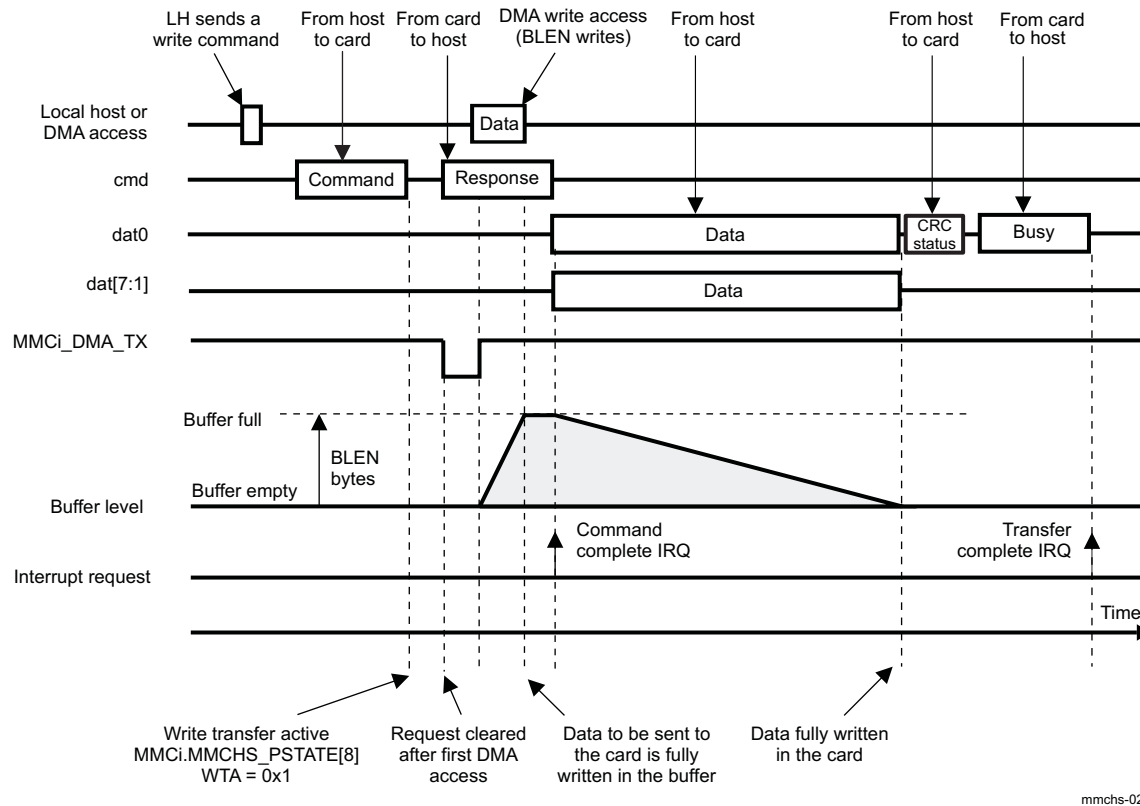

Only one request is sent per block; the DMA controller can make a 1-shot write access or multiple write DMA bursts, in which case the DMA controller must manage the number of burst accesses, according to the BLEN field block size.

New DMA requests are internally masked if the sDMA has not written exactly BLEN bytes (because DMA accesses are 32-bit accesses, the number of sDMA reads is $\text{Integer}(\text{BLEN}/4) + 1$) and if there is not enough memory space to write a complete block in the buffer.

To summarize:

- DMA transfer size = BLEN buffer size in one shot or by burst
- One DMA request per block

Figure 24-21 shows DMA transmit mode.

Figure 24-21. DMA Transmit Mode

24.4.6 Mode Selection

The MMC/SD/SDIO host controller can be used in two modes: MMC and SD/SDIO. It has been designed to be the most transparent with the type of card.

The type of the card connected is differentiated by the software initialization procedure. Software identifies the type of card connected during software initialization. For each card type, there are corresponding commands. Some commands are not supported by all cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, and *SDIO Card Specification, Part E1*.

The purpose of the module is to transfer commands and data to whatever card is connected, respecting the protocol of the connected card.

Writes and reads to the card must respect the appropriate protocol of that card.

24.4.7 Buffer Management

24.4.7.1 Data Buffer

The MMC/SD/SDIOi host controller uses a data buffer. This buffer transfers data from one data bus (interconnect) to another data bus (SD/SDIO or MMC card bus) and vice versa.

The buffer is the heart of the interface and ensures the transfer between the two interfaces (interconnect and the card).

To enhance performance, the data buffer is completed by a prefetch register and a post-write buffer that are not accessible by the host controller.

The read access time of the prefetch register is faster than that of the data buffer. The prefetch register allows data to be read from the data buffer at an increased speed by preloading data into the prefetch register.

The entry point of the data buffer, prefetch buffer, and post-write buffer is the 32-bit register `MMCi.MMCHS_DATA` register. A write access to the `MMCi.MMCHS_DATA` register followed by a read access from the `MMCi.MMCHS_DATA` register corresponds to a write access to the post-write buffer followed by a read access to the prefetch buffer. As a consequence, it is normal that the data of the write access to the `MMCi.MMCHS_DATA` register and the data of the read access to the `MMCi.MMCHS_DATA` register are different.

The number of 32-bit accesses to the `MMCi.MMCHS_DATA` register that are needed to read (or write) a data block with a size of the `MMCi.MMCHS_BLK[10:0]` `BLN` bit field equals the rounded up result of `BLN` divided by 4.

The maximum block size supported by the host controller is hard-coded in the `MMCi.MMCHS_CAPA[17:16]` `MBL` bit field and cannot be changed.

A read access to the `MMCi.MMCHS_DATA` register is allowed only when the buffer read-enable status is set to 1 (the `MMCi.MMCHS_PSTATE[11]` `BRE` bit); otherwise, a bad access (the `MMCi.MMCHS_STAT[29]` `BADA` bit) is signaled.

A write access to the `MMCi.MMCHS_DATA` register is allowed only when the buffer write-enable status is set to 1 (the `MMCi.MMCHS_PSTATE[10]` `BWE` bit); otherwise, a bad access (the `MMCi.MMCHS_STAT[29]` `BADA` bit) is signaled and the data are not written.

The data buffer has two modes of operation to store and read of the first and second portions of the data buffer:

- When the size of the data block to transfer is less than or equal to `MEM_SIZE/2` (in double-buffering), two data transfers can occur at the same time from one data bus to the other data bus, and vice versa. The MMC/SD/SDIO host controller uses the two portions of the data buffer in a ping-pong manner so that storing and reading the first and second portions of the data buffer are automatically interchanged from time to time so that data may be read from one portion (for instance, through a DMA read access on the interconnect bus) while data (for instance, from the card) are being stored into the other portion, and vice versa. When `BLN` is less than or equal to `0x200` (that is, less than or equal to 512 bytes), each of the two portions of the buffer that can be used have a size of `BLN` (that is, 32 bits × `BLN` divided by 4). No more than this total size of $2 \times 32 \text{ bits} \times \text{BLN} \text{ divided by } 4$ can be used.

CAUTION

The `MMCi.MMCHS_CMD[4]` `DDIR` bit must be configured before a transfer to indicate the direction of the transfer.

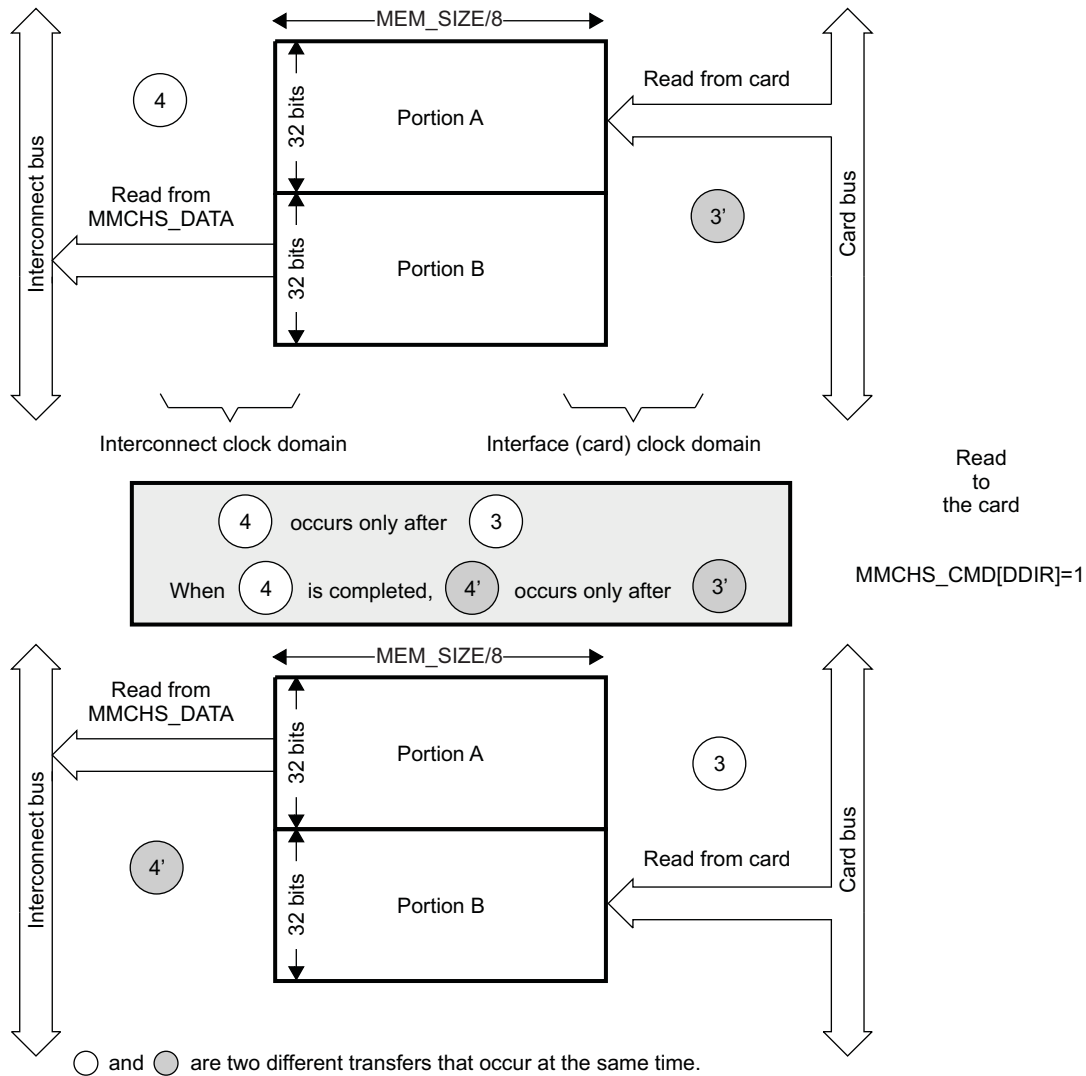

[Figure 24-22](#) and [Figure 24-23](#) show the buffer management for a write and for a read, respectively.

Figure 24-22. Buffer Management for a Write

mmchs-022

Figure 24-23. Buffer Management for a Read

- When the size of the data block to transfer is larger than $MEM_SIZE/2$, only one data transfer can occur at a time from one data bus to the other data bus. The MMC/SD/SDIOi host controller uses the entire data buffer as a single portion. In this mode, a bad access (the MMCi.MMCHS_STAT[29] BADA bit) is signaled when two data transfers occur at the same time from one data bus to the other data bus, and vice versa.

24.4.7.1.1 Memory Size, Block Length, and Buffer-Management Relationship

The maximum block length and buffer management that can be targeted by the system depend on the memory depth setting (see Table 24-17).

NOTE: Double-buffering is always the buffer management for larger memory depth.

Table 24-17. Memory Size, BLEN, and Buffer Relationship

| Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes) | 512 | 1024 |
|---------------------------------------------------------|-----|------|
| Maximum block length supported | 512 | 1024 |

Table 24-17. Memory Size, BLEN, and Buffer Relationship (continued)

| Memory Size (MMCHS_HL_HWINFO[5:2] MEM_SIZE in bytes) | 512 | 1024 |
|---------------------------------------------------------|-----------|----------------|
| Double-buffering for maximum block length | N/A | BLEN<=512 |
| Single-buffering for block length | BLEN<=512 | 512<BLEN<=1024 |

NOTE: For single-buffering management, throughput on the MMC bus interface deteriorates in multiblock transfers, because the controller must wait for the filling or emptying of the buffer between each block transfer on the MMC bus. The clock is maintained on write MMC transfers (the MMCHS_CMD[3] DDIR bit is 0) and halted on read MMC transfers (the MMCHS_CMD[3] DDIR bit is 1).

24.4.7.1.2 Data Buffer Status

The data buffer status is defined in the following interrupt status register and status register:

- Interrupt status registers:
 - MMCi.MMCHS_STAT[29] BADA: Bad access to data space
 - MMCi.MMCHS_STAT[5] BRR: Buffer read ready
 - MMCi.MMCHS_STAT[4] BWR: Buffer write ready
- Status registers:
 - MMCi.MMCHS_PSTATE[11] BRE: Buffer read enable
 - MMCi.MMCHS_PSTATE[10] BWE: Buffer write enable

24.4.8 Transfer Process

The process of a transfer depends on the type of command. It can be with or without a response, and with or without data.

24.4.8.1 Different Types of Commands

Different types of commands are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*, or *SD Card Specification, Part A2*, *SD Host Controller Standard Specification*.

24.4.8.2 Different Types of Responses

Different types of responses are specific to the MMC, SD, and SDIO cards. For more information, see the *Multimedia Card System Specification*, *SD Memory Card Specifications*, *SDIO Card Specification, Part E1*, or the *SD Card Specification, Part A2*, *SD Host Controller Standard Specification*.

Table 24-18 describes how the MMC, SD, and SDIO responses are stored in the MMCHS_RSPxx registers.

Table 24-18. MMC, SD, SDIO Responses in the MMCHS_RSPxx Registers

| Kind of Response | Response Field | Response Register |
|----------------------------------------------------|----------------------------|----------------------------------------------------------------------------------|
| R1, R1b (normal response), R3, R4, R5, R5b, R6, R7 | RESP[39:8] ⁽¹⁾ | MMCHS_RSP10[31:0] |
| R1b (Auto CMD12 response) | RESP[39:8] ⁽¹⁾ | MMCHS_RSP76[31:0] |
| R2 | RESP[127:0] ⁽¹⁾ | MMCHS_RSP76[31:0] MMCHS_RSP54[31:0] MMCHS_RSP32[31:0] MMCHS_RSP10[31:0] |

⁽¹⁾ RESP refers to the command response format described in the specifications mentioned.

When the host controller modifies part of the MMCHS_RSPxx registers, it preserves the unmodified bits.

The host controller stores the Auto CMD12 response in the MMCHS_RSP76[31:0] register because the host controller may have a multiple block data DAT line transfer executing concurrently with a command. This lets the host controller avoid overwriting the Auto CMD12 response with the command response stored in the MMCHS_RSP10 register, and vice versa.

24.4.9 Transfer or Command Status and Errors Reporting

Flags in the MMC/SD/SDIOi host controller show the status of communication with the card:

- A time-out (of a command, data, or response)
- A CRC error

Error conditions generate interrupts. For more information, see [Table 24-19](#) and the register description.

Table 24-19. CC and TC Values Upon Error Detected

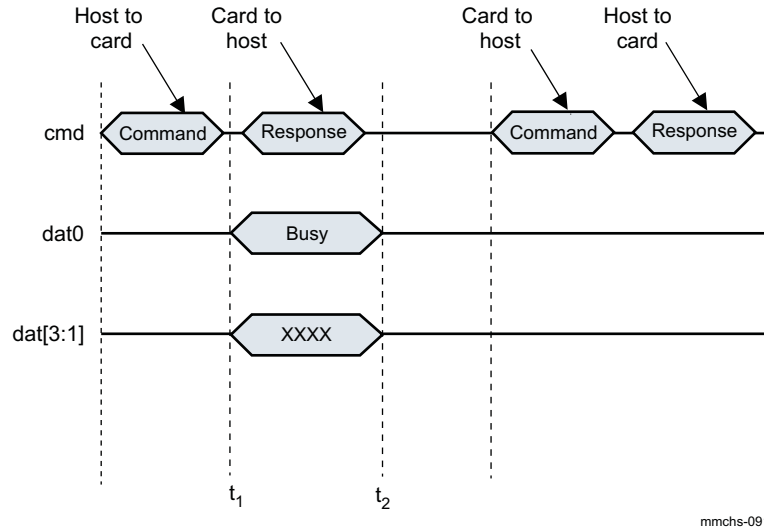

| Error Hold in MMCi.MMCHS_STAT | CC | TC | Comments |
|-------------------------------|----|----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 29 BADA | | | No dependency with CC or TC BADA is related to the MMCHS_DATA register accesses. Its assertion does not depend on the ongoing transfer. |
| 28 CERR | 1 | | CC is set upon CERR. |
| 22 DEB | | 1 | TC is set upon DEB. |
| 21 DCRC | | 1 | TC is set upon DCRC. |
| 20 DTO | | | DTO and TC are mutually exclusive. DCRC and DEB cannot occur with DTO. |
| 19 CIE | 1 | | CC is set upon CIE. |
| 18 CEB | 1 | | CC is set upon CEB. |
| 17 CCRC | 1 | | CC can be set upon CCRC. See CTO comment. |
| 16 CTO | | | CTO and CC are mutually exclusive. CIE, CEB, and CERR cannot occur with CTO. CTO can occur at the same time as CCRC: It indicates a command abort due to contention on the CMD line. In this case no CC appears. |

A MMCHS_STAT[21] DCRC event can be asserted in the following conditions:

- Busy time-out for R1b, R5b response type
- Busy time-out after write CRC status
- Write CRC status time-out
- Read data time-out
- Boot acknowledge time-out

24.4.9.1 Busy Time-Out for R1b, R5b Response Type

[Figure 24-24](#) shows the DCRC event condition asserted when there is busy time-out for Rb1, R5b response.

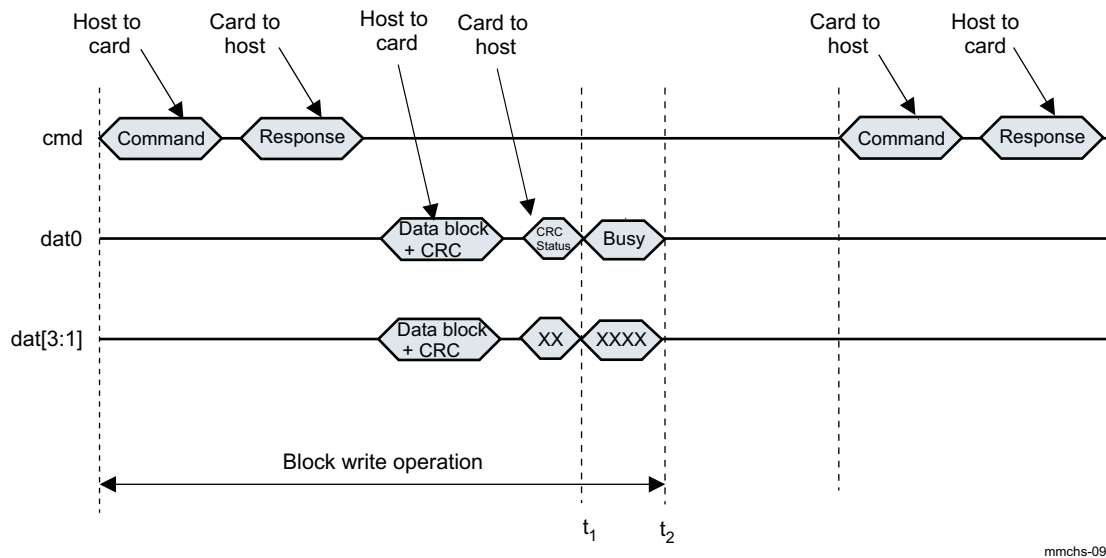

Figure 24-24. Busy Time-Out for R1b, R5b Response Type

t_1 – Data time-out counter is loaded and starts after R1b, R5b response type.

t_2 – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.

24.4.9.2 Busy Time-Out After Write CRC Status

Figure 24-25 shows the DCRC event condition asserted when there is busy time-out after write CRC status.

Figure 24-25. Busy Time-Out After Write CRC Status

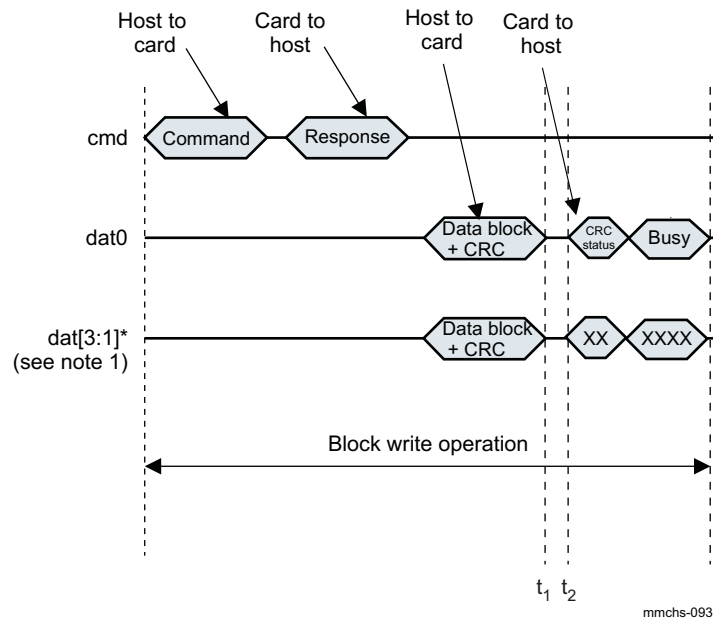

t_1 – Data time-out counter is loaded and starts after CRC status.

t_2 – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.

24.4.9.3 Write CRC Status Time-Out

Figure 24-26 shows the DCRC event condition asserted when there is write CRC status time-out.

Figure 24-26. Write CRC Status Time-Out

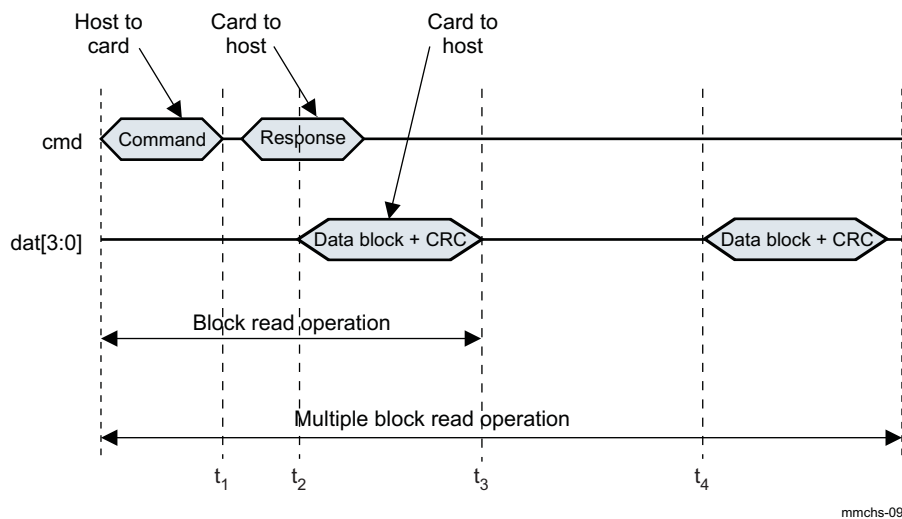

t₁ – Data time-out counter is loaded and starts after data block + CRC.

t₂ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

24.4.9.4 Read Data Time-Out

Figure 24-27 shows the DCRC event condition asserted when there is read data time-out.

Figure 24-27. Read Data Time-Out

t₁ – Data time-out counter is loaded and starts after command transmission.

t₂ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

t₃ – Data time-out counter is loaded and starts after data block + CRC transmission.

t₄ – Data time-out counter stops and if it is 0, the [MMCHS_STAT\[21\]](#) DCRC bit is generated.

24.4.9.5 Boot Acknowledge Time-Out

Figure 24-28 shows the DCRC event condition asserted when there is a boot acknowledge time-out and CMD0 is used.

Figure 24-28. Boot Acknowledge Time-Out When Using CMD0

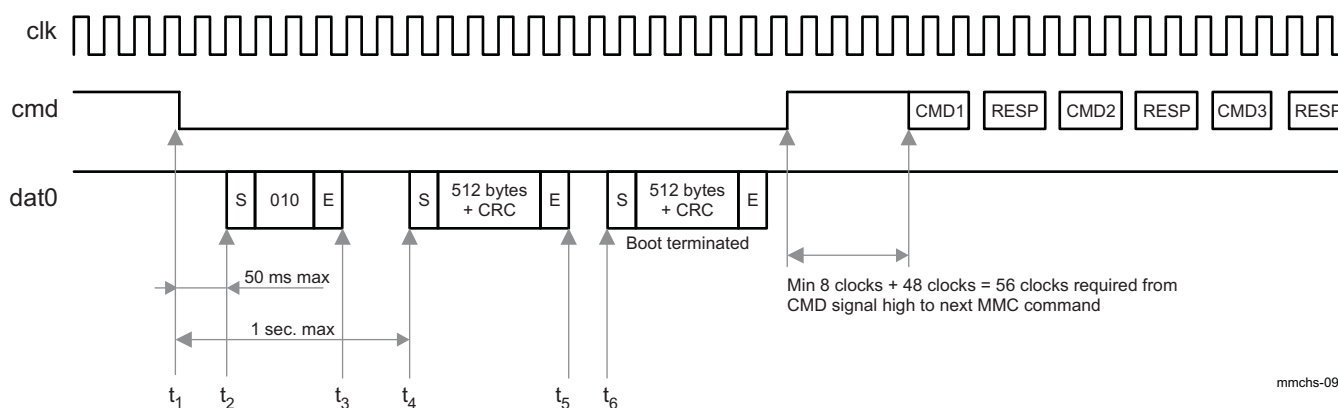

* Refer to MMC specification for correct Argument

mmchs-095

- t_1 – Data time-out counter is loaded and starts after CMD0.
- t_2 – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.
- t_3 – Data time-out counter is loaded and starts.
- t_4 – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.
- t_5 – Data time-out counter is loaded and starts after data + CRC transmission.
- t_6 – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.

Figure 24-29 shows the DCRC event condition asserted when there is boot acknowledge time-out when the CMD line is tied to 0.

Figure 24-29. Boot Acknowledge Time-Out When CMD Line Tied to 0

mmchs-096

- t_1 – Data time-out counter is loaded and starts after the CMD line is tied to 0.
- t_2 – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.
- t_3 – Data time-out counter is loaded and starts.
- t_4 – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.
- t_5 – Data time-out counter is loaded and starts after data + CRC transmission.
- t_6 – Data time-out counter stops and if it is 0, the `MMCHS_STAT[21]` DCRC bit is generated.

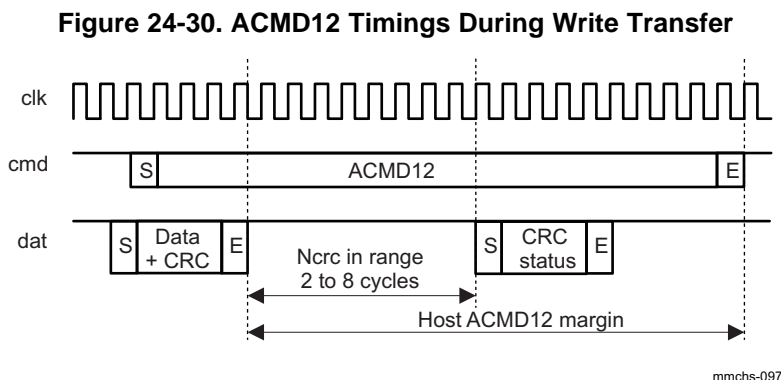

24.4.10 Auto Command 12 Timings

With the UHS definition of SD cards with higher frequency for MMC clock up to 208, the SD standard imposes a specific timing for the arrival of the auto command 12 (ACMD12) end bit.

24.4.10.1 ACMD12 Timings During Write Transfer

A margin named *Nrc* in the range of two to eight cycles has been defined for SDR50 card components for write data transfers, because the ACMD12 end bit must arrive after the CRC status end bit.

Figure 24-30 shows the ACMD12 timings during write transfer.

The host controller has a margin of 18 clock cycles to ensure that the ACMD12 end bit arrives after the CRC status. This margin does not depend on the MMC bus configuration, DDR, or standard transfer, 1-, 4-, or 8-bit bus width.

24.4.10.2 ACMD12 Timings During Read Transfer

With UHS cards, the gap timing between two successive cards has been extended from two cycles to four cycles. It provides more flexibility for the host ACMD12 arrival to receive the last complete and reliable block. The MMCHS controller follows only the left border case defined by the SD UHS specification.

Figure 24-31 shows ACMD12 timings during read transfer.

The ACMD12 arrival sent by the host controller is not sensitive to the MMC bus configuration, whether it is a DDR or standard transfer and whether it is a 1-, 4-, or 8-bit bus width transfer.

24.4.11 Transfer Stop

Whenever a transfer is initiated, the transmission may be willed to stop while it is still not finished. Several cases are possible, depending on the transfer type:

- Multiple-block-oriented transfers (transfer length is known)
- Continuous stream transfers (transfer has an infinite length)

NOTE: Because the MMC/SD/SDIOi controller manages transfers based on a block granularity, the buffer accepts a block only if there is enough space to store it completely. Consequently, if a block is pending in the buffer, no command is sent to the card because the card clock will be shut off by the controller.

The MMC/SD/SDIOi controller includes two features that make a transfer stop more convenient and easier to manage:

- ACMD12 (for MMC and SD only):

This feature is enabled by setting the MMCI.MMCHS_CMD[2] ACEN bit to 0x1 (this setting is relevant for a MMC/SD transfer with a known number of blocks to transfer). When the ACMD12 feature is enabled, the MMC/SD/SDIOi controller automatically issues a CMD12 command when the expected number of blocks is exchanged.

- Stop at block gap:

This feature is enabled by setting the MMCI.MMCHS_HCTL[16] SBGR bit to 0x1. When enabled, this capability holds the transfer on until the end of a block boundary. If a stop transmission is needed, software can use this pause to send a CMD12 to the card.

- ADMA mode:

For ADMA-capable modules (MMC1 and MMC2) (for more information, see [Section 24.4.5, DMA Modes](#)), the last instruction can stop the transfer (the END bit is enabled in the descriptor line).

NOTE: For MMC and SD cards, the stop-at-block-gap feature is not supported in read mode.

For SDIO cards, this setting can be supported in read mode if the card has a read-wait capability.

[Table 24-20](#) shows the common way to stop a transfer, indicating the command to send and the features to enable.

Table 24-20. MMC/SD/SDIOi Controller Transfer Stop Command Summary

| | | Write Transfer | | Read Transfer | |
|-------------------------------------|-----------------------------------------------------------|-----------------------------------------------------------|------------------------------------------------------------------------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| | | SD/MMC | SDIO | SD/MMC | SDIO |
| Single block | | Transfer ends automatically. Wait TC. | Transfer ends automatically. Wait TC. | Transfer ends automatically. Wait TC. | Transfer ends automatically. Wait TC. |
| Multiblocks (finite or infinite) | Before the programmed block boundary | Send CMD12. Wait TC. | Send CMD52. Wait TC. | Send CMD12. Wait TC. | Send CMD52. Wait TC. |
| | Stop at the end of the transfer (finite transfer only) | ACMD12 active Transfer ends automatically. Wait TC. | Set MMCI.MMCHS_HCTL[16] SBGR bit to 0x1. Send CMD52. Wait TC. | ACMD12 active Transfer ends automatically. Wait TC. | If READ_WAIT supported Stop at block gap. Wait TC. <hr/> If READ_WAIT not supported Send CMD52. Wait TC. |

NOTE: The MMC/SD/SDIOi controller sends the stop command to the card on a block boundary, regardless of when the command was written to the controller registers.

24.4.12 Retention Mode

This mode is enabled if the generic parameter bit `MMCHS_HL_HWINFO[6] RETMODE` is set to 1 during module integration. The controller can enter into retention mode when the module was previously set in idle mode. When the module goes into retention mode all clocks are left inactive at low level except for registers that are driven by a falling-edge clock, which are kept as free during retention mode. This also means that all divided functional clock subdomains are forced low when the module enters smart-idle mode. In force-idle mode, the system must ensure that all divided functional clocks are set inactive or are in bypass mode by configuring the `MMCHS_SYSCTL` register correctly before entering idle mode (under software responsibility).

24.4.13 Output Signals Generation

The MMC/SD/SDIO output signals can be driven on the falling edge or rising edge, depending on the `MMCHS_HCTL[2] HSPE` bit. This feature allows reaching better timing performance, and thus increasing data transfer frequency.

24.4.13.1 Generation on Falling Edge of MMC Clock

The controller is by default in this mode to maximize hold timings. In this case, the `MMCHS_HCTL[2] HSPE` bit is set to 0.

Figure 24-32 shows the output signals of the module when generating from the falling edge of the MMC clock.

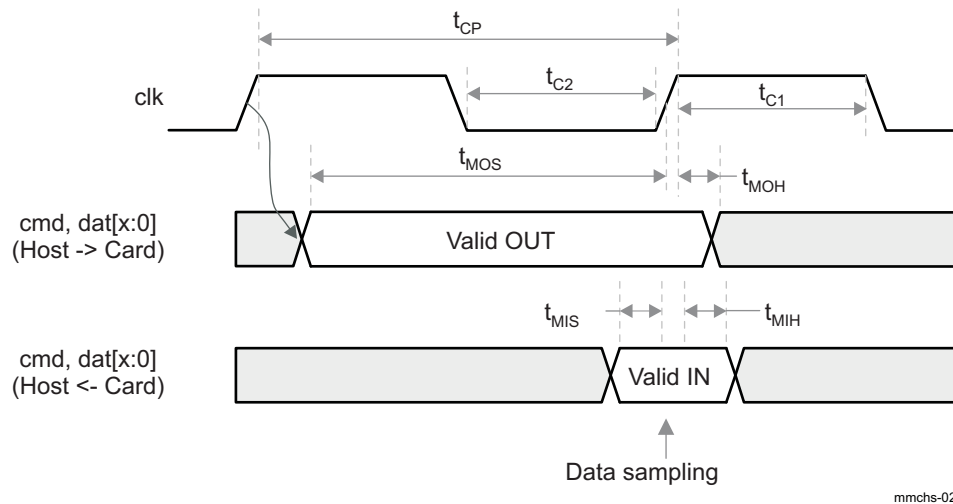

mmchs-024

24.4.13.2 Generation on Rising Edge of MMC Clock

This mode increases setup timings and allows reaching higher bus frequency. This feature is activated by setting the `MMCHS_HCTL[2] HSPE` bit to 1. The controller must be set in this mode to support SDR transfers.

NOTE: Do not use this feature in DDR mode (when the `MMCHS_CON[19] DDR` bit is set to 1).

Figure 24-33 shows the output signals of the module when generating from the rising edge of the MMC clock.

Figure 24-33. Output Driven on Rising Edge

24.4.14 Card Boot Mode Management

Boot operation mode allows the MMC/SD/SDIOi host controller to read boot data from the connected slave (MMC device) by keeping CMD line low after power on (or sending CMD0 with a specific argument) before issuing CMD1. The data can be read from the boot area or user area, depending on the register setting.

Power-on boot defines a way for the boot code to be accessed by the MMC/SD/SDIOi host controller without an upper-level software driver, speeding the time it takes for a controller to access the boot code.

The two possible ways to issue a boot command (issuing a CMD0 or driving the CMD line to 0 during the whole boot phase) are described in the following sections.

24.4.14.1 Boot Mode Using CMD0

Figure 24-34 shows the timing diagram of a boot sequence using CMD0.

Figure 24-34. Boot Mode Using the CMD0 Timing Diagram

* Refer to MMC specification for correct Argument

mmchs-026

For more information about how to configure the MMC/SD/SDIO host controller, see [Section 24.5.1.2.3.1, Boot Using the CMD0](#).

24.4.14.2 Boot Mode With CMD Line Tied to 0

Figure 24-35 shows the timing diagram of a boot sequence with CMD line tied to 0.

Figure 24-35. Boot Mode With CMD Line Tied to 0 Timing Diagram

mmchs-027

For more information about how to configure the MMC/SD/SDIO host controller, see [Section 24.5.1.2.3.2, Boot With CMD Line Tied to 0](#).

24.4.15 MMC CE-ATA Command Completion Disable Management

The MMC/SD/SDIOi host controller supports CE-ATA features, in particular the detection of command completion token. When a command that requires a command completion signal (the [MMCHS_CON\[12\]](#) CEATA and [MMCHS_CMD\[2\]](#) ACEN bits set to 1) is launched, the host system is no longer allowed to emit a new command in parallel to the data transfer unless it is a command completion disable token.

The settings to emit a command completion disable token are:

- The [MMCHS_CON\[12\]](#) CEATA bit is set to 1.
- The [MMCHS_CON\[2\]](#) bit HR set to 1.
- Clear the [MMCHS_ARG](#) register.
- Write into the [MMCHS_CMD](#) register with the value 0x00000000.

When a command completion disable token was emitted (that is, the [MMCHS_STAT\[0\]](#) CC bit received), the host system is again allowed to emit another type of command (for example, a CMD12 to abort transfer).

A critical case can be encountered when command completion signal disable (CCSD) is emitted during the last data block transfer, and the sequence on the command line is sent close to the command completion signal (CCS) token sent by the card.

Three possible cases are:

- CCS is received immediately before CCSD is emitted:
An interrupt CIRQ is generated with CCS detection, CCSD is transmitted to the card, and then an interrupt CC is generated when CCSD ends. In this case, the card considers the CCSD sequence.
- CCS is not generated or is generated during the CCSD transfer:
The CCS bit cannot be detected (conflict is not possible because they drive the same level on the command line, and no CIRQ interrupt is generated; a CC interrupt is generated when CCSD ends).
- CCS is generated without CCSD token required:
Only the interrupt CIRQ is generated when CCS is detected.

24.4.16 Test Registers

Test registers are available to comply with the *SD Host Controller Specification*. This feature is useful to generate interrupts manually for driver debugging.

The force event register ([MMCHS_FE](#)) is used to control the error interrupt status and ACMD12 error status.

The system test register ([MMCHS_SYSTEST](#)) is used to control the signals that connect to I/O pins when the module is configured in the system test mode (the [MMCHS_CON\[4\]](#) MODE bit = 1) for boundary connectivity verification.

24.4.17 MMC/SD/SDIO Hardware Status Features

[Table 24-21](#) describes the MMC/SD/SDIO hardware status features.

Table 24-21. MMC/SD/SDIO Hardware Status Features

| Feature | Type | Register/Bit Field/Observability Control | Description |
|-----------------------------|--------|------------------------------------------------------------------|-----------------------------------------------------------------------------------|
| Interrupt flags | | See Section 24.4.4 , <i>Interrupt Requests</i> . | |
| CMD line signal level | Status | MMCHS_PSTATE[24] CLEV | Indicates the level of the command line |
| DAT lines signal level | Status | MMCHS_PSTATE[23:20] DLEV | Indicates the level of the data lines |
| Buffer read enable | Status | MMCHS_PSTATE[11] BRE | Readable data exists in the buffer. |
| Buffer write enable | Status | MMCHS_PSTATE[10] BWE | Indicates whether there is enough space in the buffer to write BLEN bytes of data |
| Read transfer active | Status | MMCHS_PSTATE[9] RTA | Used to detect completion of a read transfer. |
| Write transfer active | Status | MMCHS_PSTATE[8] WTA | Indicates a write transfer active |
| Data line active | Status | MMCHS_PSTATE[2] DLA | Indicates whether the data lines are active |
| Command Inhibit (DAT lines) | Status | MMCHS_PSTATE[1] DATI | Indicates whether issuing of command using data lines is allowed |
| Command inhibit (CMD line) | Status | MMCHS_PSTATE[0] CMDI | Indicates whether issuing of command using command line is allowed |

24.5 MMC/SD/SDIO Programming Guide

24.5.1 Low-Level Programming Models

24.5.1.1 Global Initialization

24.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the module must be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the MMC/SD/SDIO modules. For more information, see [Section 24.3, MMC/SD/SDIO Integration](#), and [Section 24.2, MMC/SD/SDIO Environment](#).

Table 24-22. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|-----------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| PRCM | Module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management . |
| Control module | Module-specific pad muxing and configuration must be set in the control module. See Chapter 18, Control Module . |
| (optional) MPU INTC (or DSP INTC) | MPU INTC configuration must be done to enable the interrupts from the MMCHS module. See Chapter 17, Interrupt Controllers . |
| (optional) sDMA (or dDMA) | DMA configuration must be done to enable the module DMA channel requests. See Chapter 16, sDMA . |
| (optional) Interconnect | For more information about the interconnect configuration, see Chapter 13, Interconnect . |

NOTE: The MPU/DSP INTC and the sDMA/dDMA configurations are necessary if the interrupt and DMA-based communication modes are used.

24.5.1.1.2 MMC/SD/SDIO Host Controller Initialization Flow

[Table 24-23](#) shows the general boot process.

Table 24-23. MMC/SD/SDIO Controller Meta Initialization Steps

| Step | Access Type | Register/Bit Field/Programming Model | Value |
|------------------------------------|-------------|--------------------------------------------|-------|
| Initialize clocks. | | See Section 24.5.1.1.2.1 . | |
| Software reset of the controller. | | See Section 24.5.1.1.2.2 . | |
| Set module hardware capabilities. | | See Section 24.5.1.1.2.3 . | |
| Set module idle and wake-up modes. | | See Section 24.5.1.1.2.4 . | |

24.5.1.1.2.1 Enable Interface and Functional clock for MMC Controller

Before any MMCHS register access, the MMCHS interface clock and functional clock in the PRCM module registers must be enabled. See [Section 3.6.4.4, Clock Domain Module Attributes](#), in [Chapter 3, Power, Reset, and Clock Management](#).

24.5.1.1.2.2 MMCHS Soft Reset Flow

[Figure 24-36](#) shows the soft reset process of the MMCHS controller.

Figure 24-36. MMC/SD/SDIO Controller Software Reset Flow

mmchs-028

Table 24-24. Register Call Summary for Main Sequence – Software Reset Flow

| Register Name | Register Name |
|-----------------|-----------------|
| MMCHS_SYSCONFIG | MMCHS_SYSSTATUS |

24.5.1.1.2.3 Set MMCHS Default Capabilities

Software must read capabilities (in boot ROM, for example) and is allowed to set (write) the MMCi.MMCHS_CAPA[26:24] and MMCi.MMCHS_CUR_CAPA[23:0] bit fields before the MMC/SD/SDIO host driver is started.

24.5.1.1.2.4 Wake-Up Configuration

Table 24-25 describes the MMCHS controller wake-up configuration.

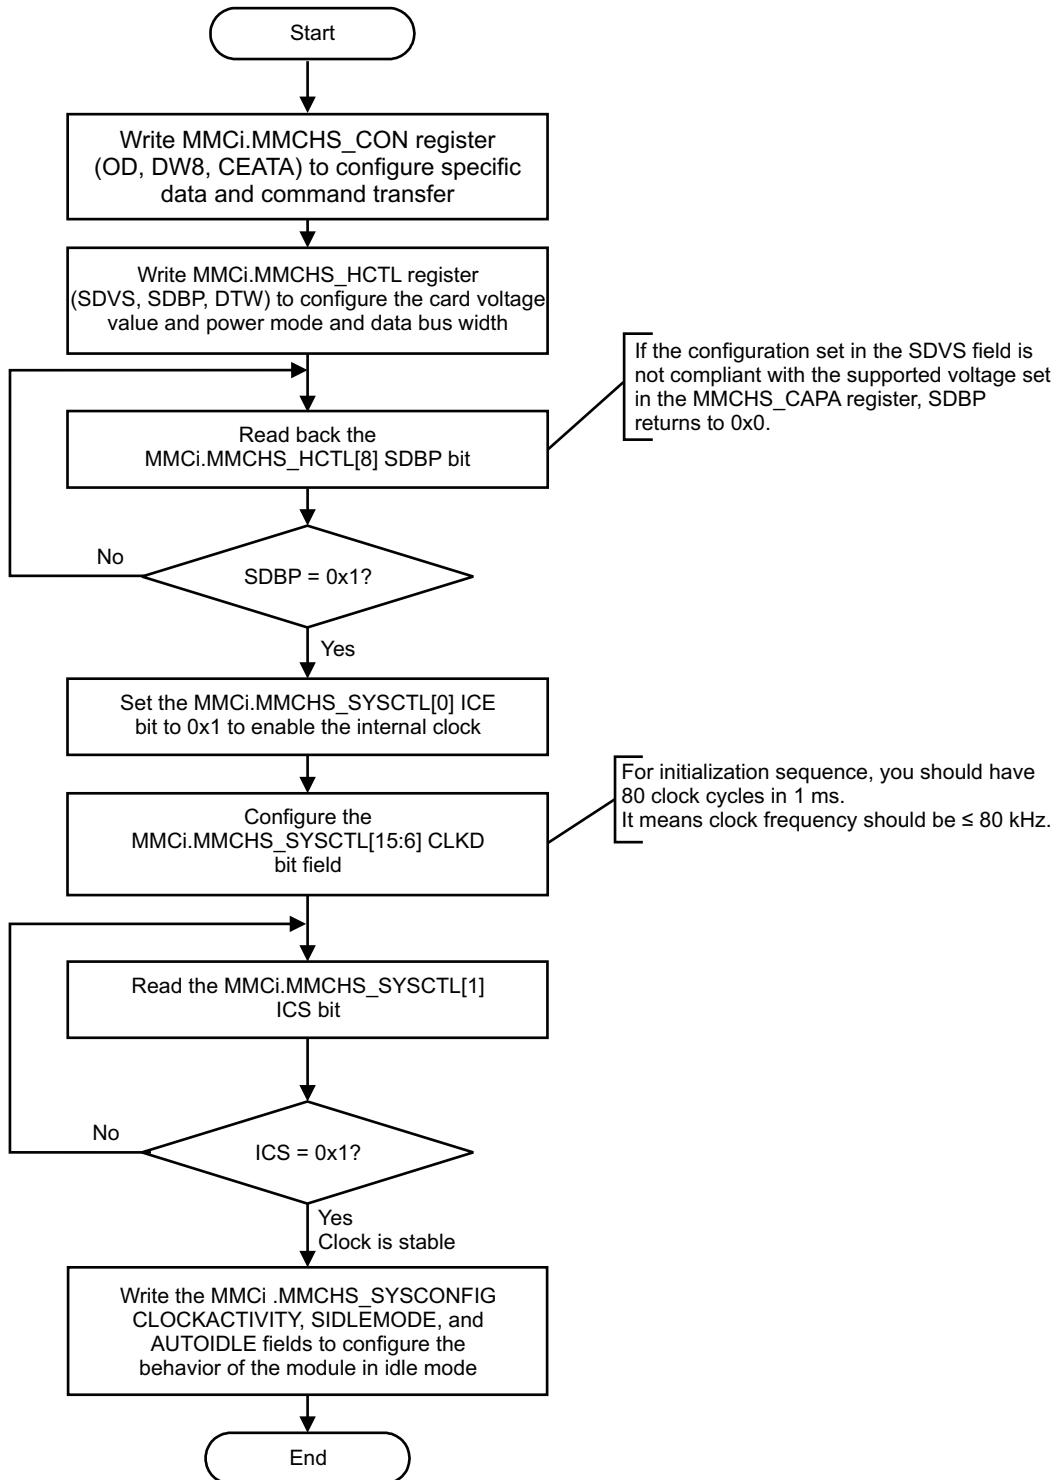

Table 24-25. MMC/SD/SDIO Controller Wake-Up Configuration

| Step | Access Type | Register/Bit Field/Programming Model | Value |
|--------------------------------------------------------------|-------------|--------------------------------------|-------|
| Configure wake-up bit (if necessary). | W | MMCi.MMCHS_SYSCONFIG[2] ENAWAKEUP | 0x1 |
| Enable wake-up events on SD card interrupt (if necessary). | W | MMCi.MMCHS_HCTL[24] IWE | 0x1 |
| SDIO card only: Enable card interrupt (if necessary). | W | MMCi.MMCHS_IE[8] CIRQ_ENABLE | 0x1 |

24.5.1.1.2.5 MMC Host and Bus Configuration

Figure 24-37 shows the MMC bus configuration process.

Figure 24-37. MMC/SD/SDIO Controller Bus Configuration

mmchs-029

Table 24-26. Register Call Summary for Main Sequence – Bus Configuration

| Register Name | Register Name |
|---------------------------------|-----------------------------|
| MMCHS_CON | MMCHS_HCTL |
| MMCHS_SYSCONFIG | MMCHS_SYCTL |

24.5.1.2 Operational Modes Configuration

24.5.1.2.1 Basic Operations for MMC/SD/SDIO Host Controller

The MMC/SD/SDIO host controller performs data transfers: data to card (referred to as write transfers) and data from card (referred to as read transfers).

The host controller requires transfers to run on a block-by-block basis rather than on a DMA burst size basis. A single DMA request (or block request interrupt) is signaled for each block. Pipelining is supported as long as the block size is less than one half of the memory buffer size.

24.5.1.2.1.1 Card Detection, Identification, and Selection

[Figure 24-38](#) and [Figure 24-39](#) show the card identification and selection process.

Figure 24-38. MMC/SD/SDIO Controller Card Identification and Selection – Part 1

mmchs-030

|---------------------------|----------------------------------------|
| Perform CMD line reset. | Section 24.5.1.2.1.1.1 |
| Perform DATA lines reset. | Section 24.5.1.2.1.2.1 |

CAUTION

CE-ATA protocol is supported only by MMC cards.

In CE-ATA mode, issuing a command during the transfer (except a CCSD command) is not allowed.

In CE-ATA mode, infinite transfers are not allowed; only finite transfers are permitted.

24.5.1.2.1.6 Suspend-Resume Flow

The suspend and resume feature is supported only by SDIO cards.

24.5.1.2.1.6.1 Suspend Flow

[Figure 24-44](#) shows the suspend flow for SDIO cards.

Figure 24-44. MMC/SD/SDIO Controller Suspend Flow

mmchs-036

| Send SWITCH command (CMD6). | Section 24.5.1.2.1.7.1 |

24.5.1.2.2 Bus Voltage Selection

The MMC/SD/SDIO1 controller can operate with two types of card voltages: 1.8 V and 3.0 V. For this reason, dual voltage pads are implemented on this interface. For technological concerns, those pads must have an internal bias voltage reference to operate. The PBIAS module supplies this bias voltage, depending on the settings of the CONTROL.CONTROL_PBIASLITE register.

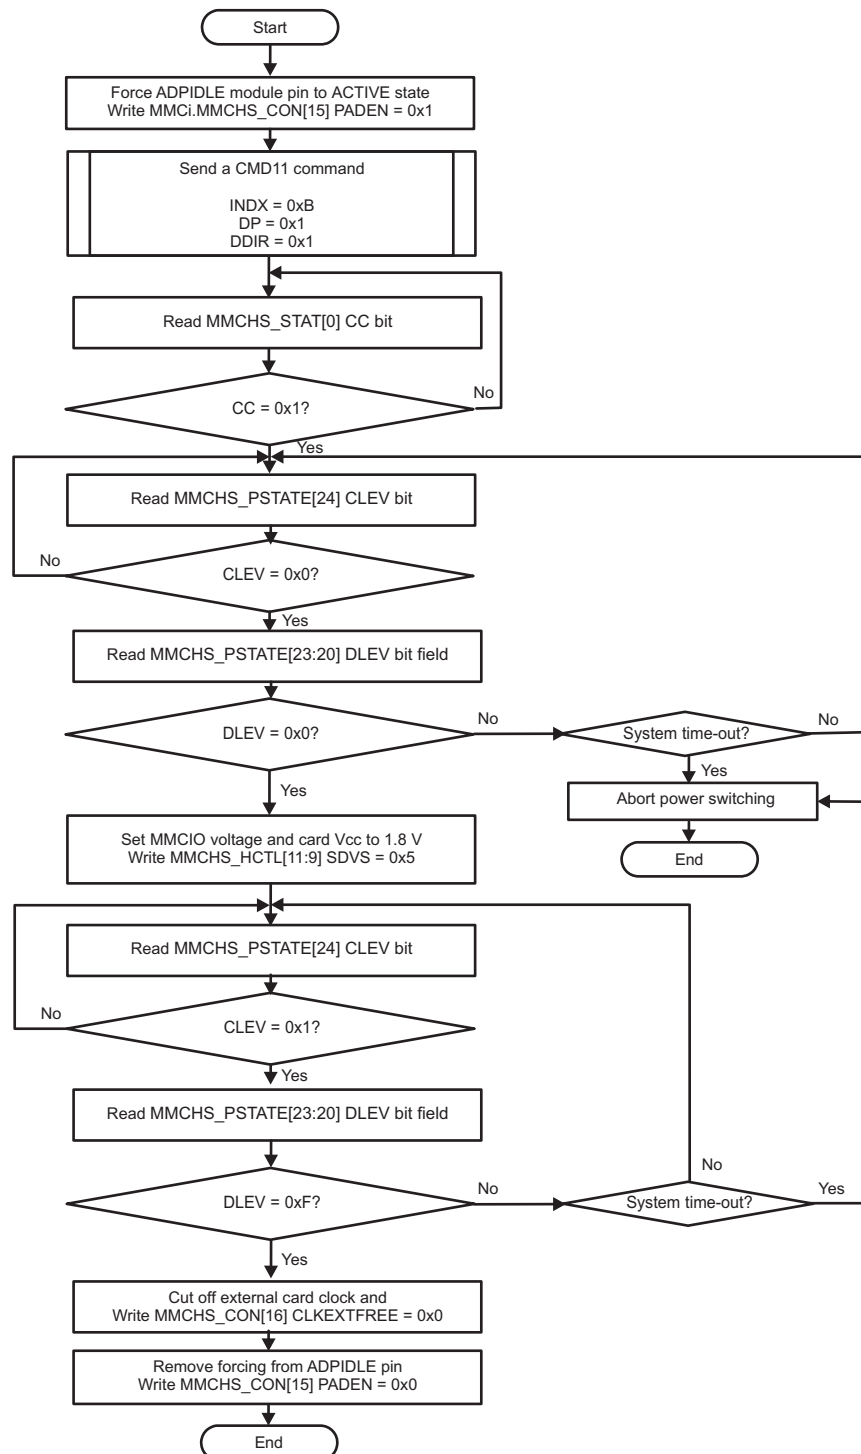

For more information about the MMC1_PBIAS cell, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#), in [Chapter 18, Control Module](#).

For the steps involved in transitioning from 1.8 V to 3.0 V and from 3.0 V to 1.8 V, applicable to the MMC/SD/SDIO1 controller, see [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cell Programming Guide](#), in [Chapter 18, Control Module](#).

CAUTION

The BIAS voltage must be set using the procedure described in [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cell Programming Guide](#), in [Chapter 18, Control Module](#). Failure to follow this procedure can damage the MMCHS interface.

[Figure 24-50](#) shows how to configure the MMCHS controller to fit with power switching sequence.

Figure 24-50. MMC/SD/SDIO Power Switching Procedure

mmchs-042

Table 24-50. Register Call Summary for Main Sequence – Power Switching Procedure

| Register Name | Register Name |

| Subprocess Name | Cross-Reference |
|---------------------------------------------|----------------------------------------|
| Send a READ_DAT_UNTIL_STOP command (CMD11). | Section 24.5.1.2.1.7.1 |

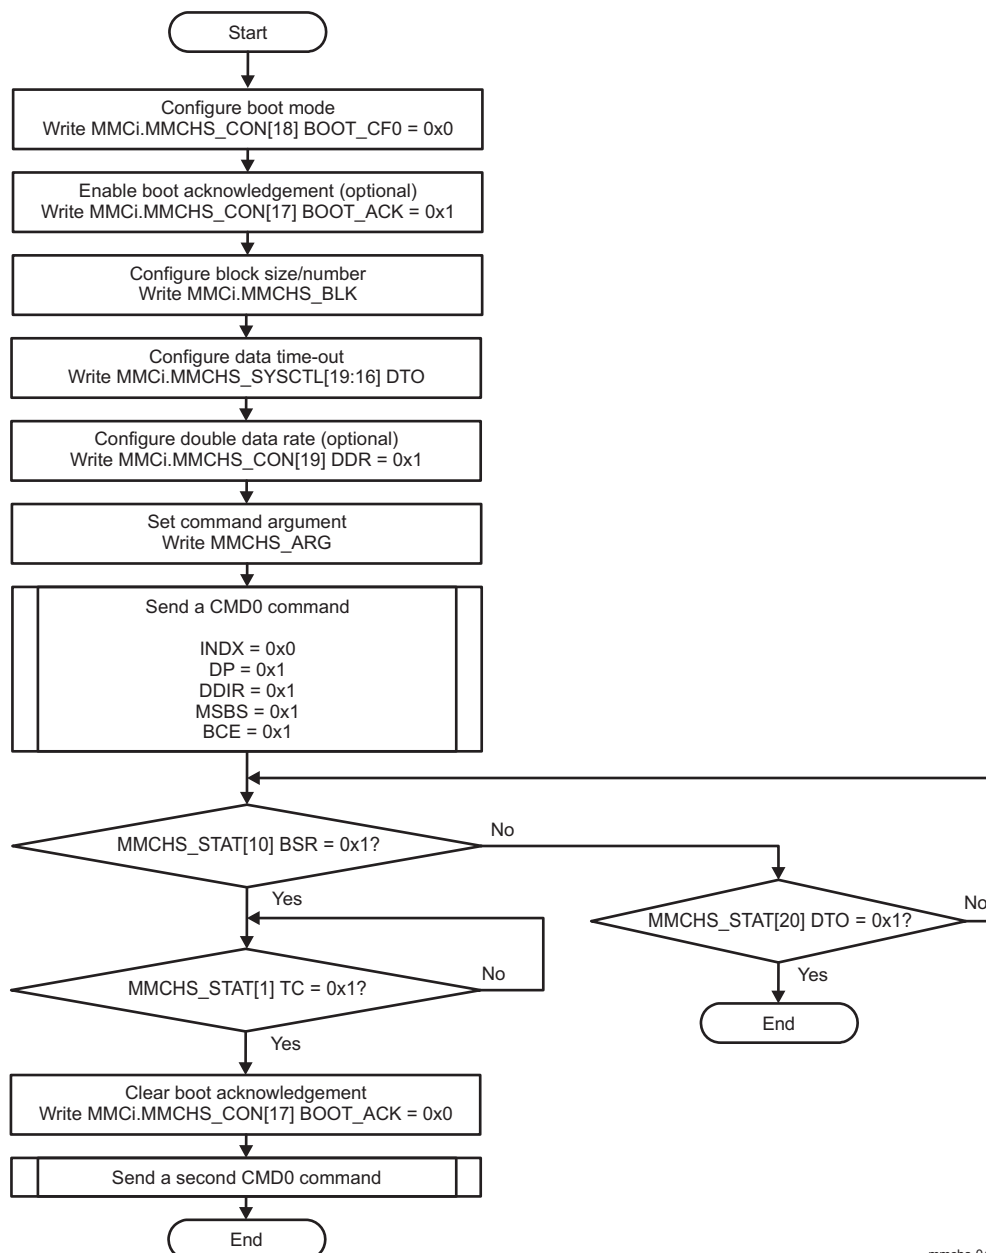

24.5.1.2.3 Boot Mode Configuration

The following sections describe the two possible ways to issue a boot command: issue a CMD0 or drive the CMD line to 0 during the whole boot phase.

24.5.1.2.3.1 Boot Using CMD0

Figure 24-51 shows the necessary steps to configure the controller boot mode using CMD0.

Figure 24-51. MMC/SD/SDIO Controller Boot Using CMD0

mmchs-043

To abort a boot sequence, the system must issue a CMD0 with the [MMCHS_CMD](#)[23:22] CMD_TYPE bit field set to 0x3 (the [MMCHS_CON](#)[17] BOOT_ACK bit previously cleared to 0x0) during the transfer to abort the transfer and enable the card to exit from boot state.

Table 24-52. Register Call Summary for Main Sequence – Boot Using CMD0

| Register Name | Register Name | Register Name |
|---------------------------|----------------------------|------------------------------|
| MMCHS_CON | MMCHS_BLK | MMCHS_SYSCTL |
| MMCHS_ARG | MMCHS_STAT | |

| Subprocess Name | Cross-Reference |
|----------------------|----------------------------------------|
| Send a CMD0 command. | Section 24.5.1.2.1.7.1 |

24.5.1.2.3.2 Boot With CMD Line Tied to 0

Figure 24-52 shows the necessary steps to configure the controller in this mode; the driver must follow this sequence.

Figure 24-52. MMC/SD/SDIO Controller Boot With CMD Line Tied to 0

mmchs-044

To abort the boot sequence, the system must clear the **MMCHS_CON[18] BOOT_CF0** bit to 0x0 during the transfer to abort the transfer and enable the card to exit from boot state.

| RESERVED | | | | | | | | | | | | | | | | | | | | | | | RETMODE | MEM_SIZE | MERGE_MEM | MADMA_EN | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-----------------------------------|
| 31:7 | RESERVED | Reserved | R | 0x00000000 |
| 6 | RETMODE | Retention mode generic parameter This bit field indicates whether the retention mode is supported using the pin PIRFFRET. 0x0: Retention mode disabled 0x1: Retention mode enabled | R | See Table 24-63 . |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------------------------------------------|
| 5:2 | MEM_SIZE | Memory size for FIFO buffer: Read 0x1: Memory of 512 bytes, max block length is 512 bytes Read 0x2: Memory of 1024 bytes, max block length is 1024 bytes Read 0x4: Memory of 2048 bytes, max block length is 2048 bytes Read 0x8: Memory of 4096 bytes, max block length is 2048 bytes | R | 0x2 |
| 1 | MERGE_MEM | Memory merged for FIFO buffer: This register defines the configuration of FIFO buffer architecture. If the bit is set STA and DFT shall support clock multiplexing and balancing. Read 0x0: 2 memories instantiated, one per data transfer direction. Read 0x1: A single memory is used with multiplexed addresses, data and clocks. | R | 0 |
| 0 | MADMA_EN | Master DMA enabled generic parameter: This register defines the configuration of the controller to know if it supports the master DMA management called ADMA. Read 0x0: No Master DMA (ADMA) management supported Read 0x1: Controller supports ADMA | R | Please refer to Table 24-64 |

| Description | Card status response error This register enables the host controller to detect card status errors of response type R1, R1b for all cards and of R5, R5b and R6 response for cards types SD or SDIO. When a bit MMCHS_CSRE[i] is set to 1, if the corresponding bit at the same position in the response MMCHS_RSP10[i] is set to 1, the host controller indicates a card error (MMCHS_STAT[CERR]) interrupt status to avoid the host driver reading the response register (MMCHS_RSP10). Note: No automatic card error detection for autoCMD12 is implemented; the host system has to check autoCMD12 response register (MMCHS_RSP76) for possible card errors. | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |

| Description | <p>System Test register</p> <p>This register is used to control the signals that connect to I/O pins when the module is configured in system test (SYSTEST) mode for boundary connectivity verification.</p> <p>Note: In SYSTEST mode, a write into MMCHS_CMD register will not start a transfer. The buffer behaves as a stack accessible only by the local host (push and pop operations). In this mode, the Transfer Block Size (MMCHS_BLK[11:0] BLEN) and the Blocks count for current transfer (MMCHS_BLK[31:16] NBLK) are needed to generate a Buffer write ready interrupt (MMCHS_STAT[4] BWR) or a Buffer read ready interrupt (MMCHS_STAT[5] BRR) and DMA requests if enabled.</p> | | |

| 31:22 | RESERVED | Reserved These bits are initialized to zero, and writes to them are ignored. Reads return 0. | R | 0x000 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 21 | SDMA_LNE | <p>Slave DMA Level/Edge Request: The waveform of the DMA request can be configured either edge sensitive with early de-assertion on first access to MMCHS_DATA register or late de-assertion, request remains active until last allowed data written into MMCHS_DATA.</p> <p>0x0: Slave DMA edge sensitive, Early DMA de-assertion 0x1: Slave DMA level sensitive, Late DMA de-assertion</p> | RW | 0 |
| 20 | DMA_MNS | <p>DMA Master or Slave selection: When this bit is set and the controller is configured to use the DMA, Interconnect master interface is used to get datas from system using ADMA2 procedure (direct access to the memory). This option is only available if generic parameter MMCHS_HL_HWINFO[0] MADMA_EN is asserted to 1.</p> <p>0x0: The controller is slave on data transfers with system. 0x1: The controller is master on data exchange with system, controller must be configured as using DMA.</p> | RW | 0 |
| 19 | DDR | <p>Dual Data Rate mode: When this register is set, the controller uses both clock edge to emit or receive data. Odd bytes are transmitted on falling edges and even bytes are transmitted on rise edges. It only applies on Data bytes and CRC, Start, end bits and CRC status are kept full cycle. This bit field is only meaningful and active for even clock divider ratio of MMCHS_SYSCTL[15:6] CLKD, it is insensitive to MMCHS_HCTL[2] HSPE setting.</p> <p>0x0: Standard mode : data are transmitted on a single edge depending on MMCHS_HCTL[2] HSPE. 0x1: Data Bytes and CRC are transmitted on both edge.</p> | RW | 0 |
| 18 | BOOT_CFO | <p>Boot status supported: This register is set when the CMD line need to be forced to 0 for a boot sequence. CMD line is driven to 0 after writing in MMCHS_CMD. The line is released when this bit field is de-asserted and abort data transfer in case of a pending transaction.</p> <p>Write 0x0: CMD line is released when it was previously forced to 0 by a boot sequence. Read 0x0: CMD line not forced Read 0x1: CMD line forced to 0 is enabled Write 0x1: CMD line forced to 0 is enabled and will be active after writing into MMCHS_CMD</p> | RW | 0 |
| 17 | BOOT_ACK | <p>Book acknowledge received: When this bit is set the controller should receive a boot status on DAT0 line after next command issued. If no status is received a data timeout will be generated.</p> <p>0x0: No acknowledge to be received 0x1: A boot status will be received on DAT0 line after issuing a command.</p> | RW | 0 |
| 16 | CLKEXTFREE | <p>External clock free running: This register is used to maintain card clock out of transfer transaction to enable slave module for example to generate a synchronous interrupt on DAT[1]. The Clock will be maintain only if MMCHS_SYSCTL[2] CEN is set.</p> <p>0x0: External card clock is cut off outside active transaction period. 0x1: External card clock is maintain even out of active transaction period only if MMCHS_SYSCTL[2] CEN is set.</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 15 | PADEN | <p>Control Power for MMC Lines: This register is only useful when MMC PADs contain power saving mechanism to minimize its leakage power. It works as a GPIO that directly control the ACTIVE pin of PADs. Excepted for DAT[1], the signal is also combine outside the module with the dedicated power control MMCHS_CON[11] CTPL bit.</p> <p>0x0: ADPIDLE module pin is not forced, it is automatically generated by the MMC fsms.</p> <p>0x1: ADPIDLE module pin is forced to active state.</p> | RW | 0 |
| 14 | OBIE | <p>Out-of-Band Interrupt Enable MMC cards only: This bit enables the detection of Out-of-Band Interrupt on MMCOBI input pin. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: Out-of-Band interrupt detection disabled</p> <p>0x1: Out-of-Band interrupt detection enabled</p> | RW | 0 |
| 13 | OBIP | <p>Out-of-Band Interrupt Polarity MMC cards only: This bit selects the active level of the out-of-band interrupt coming from MMC cards. The usage of the Out-of-Band signal (OBI) is optional and depends on the system integration.</p> <p>0x0: active high level</p> <p>0x1: active low level</p> | RW | 0 |
| 12 | CEATA | <p>CE-ATA control mode MMC cards compliant with CE-ATA:By default, this bit is set to 0. It is use to indicate that next commands are considered as specific CE-ATA commands that potentially use 'command completion' features.</p> <p>0x0: Standard MMC/SD/SDIO mode.</p> <p>0x1: CE-ATA mode next commands are considered as CE-ATA commands.</p> | RW | 0 |
| 11 | CTPL | <p>Control Power for DAT[1] line MMC and SD cards: By default, this bit is set to 0 and the host controller automatically disables all the input buffers outside of a transaction to minimize the leakage current.</p> <p>SDIO cards: When this bit is set to 1, the host controller automatically disables all the input buffers except the buffer of DAT[1] outside of a transaction in order to detect asynchronous card interrupt on DAT[1] line and minimize the leakage current of the buffers.</p> <p>0x0: Disable all the input buffers outside of a transaction.</p> <p>0x1: Disable all the input buffers except the buffer of DAT[1] outside of a transaction.</p> | RW | 0 |
| 10:9 | DVAL | <p>Debounce filter value All cards This register is used to define a debounce period to filter the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: 33 us debounce period</p> <p>0x1: 231 us debounce period</p> <p>0x2: 1 ms debounce period</p> <p>0x3: 8,4 ms debounce period</p> | RW | 0x3 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 8 | WPP | <p>Write protect polarity For SD and SDIO cards only This bit selects the active level of the write protect input signal (SDWP). The usage of the write protect input signal (SDWP) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: active high level 0x1: active low level</p> | RW | 0 |
| 7 | CDP | <p>Card detect polarity All cards This bit selects the active level of the card detect input signal (SDCD). The usage of the card detect input signal (SDCD) is optional and depends on the system integration and the type of the connector housing that accommodates the card.</p> <p>0x0: active high level 0x1: active low level</p> | RW | 0 |
| 6 | MIT | <p>MMC interrupt command Only for MMC cards. This bit must be set to 1, when the next write access to the command register (MMCHS_CMD) is for writing a MMC interrupt command (CMD40) requiring the command timeout detection to be disabled for the command response.</p> <p>0x0: Command timeout enabled 0x1: Command timeout disabled</p> | RW | 0 |
| 5 | DW8 | <p>8-bit mode MMC select For SD/SDIO cards, this bit must be set to 0. For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliancy with MMC standard specification 4.x (see section 3.6).</p> <p>0x0: 1-bit or 4-bit Data width (DAT[0] used, MMC, SD cards) 0x1: 8-bit Data width (DAT[7:0] used, MMC cards)</p> | RW | 0 |
| 4 | MODE | <p>Mode select All cards These bits select between Functional mode and SYSTEST mode.</p> <p>0x0: Functional mode. Transfers to the MMC/SD/SDIO cards follow the card protocol. MMC clock is enabled. MMC/SD transfers are operated under the control of the CMD register.</p> <p>0x1: SYSTEST mode The signal pins are configured as general-purpose input/output and the 1024-byte buffer is configured as a stack memory accessible only by the local host or system DMA. The pins retain their default type (input, output or in-out). SYSTEST mode is operated under the control of the SYSTEST register.</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 3 | STR | <p>Stream command Only for MMC cards. This bit must be set to 1 only for the stream data transfers (read or write) of the adtc commands. Stream read is a class 1 command (CMD11: READ_DAT_UNTIL_STOP). Stream write is a class 3 command (CMD20: WRITE_DAT_UNTIL_STOP).</p> <p>0x0: Block oriented data transfer 0x1: Stream oriented data transfer</p> | RW | 0 |
| 2 | HR | <p>Broadcast host response Only for MMC cards. This register is used to force the host to generate a 48-bit response for bc command type. It can be used to terminate the interrupt mode by generating a CMD40 response by the core (see section 4.3, "Interrupt Mode", in the MMC [1] specification). In order to have the host response to be generated in open drain mode, the register MMCHS_CON[0] OD must be set to 1. When MMCHS_CON[12] CEATA is set to 1 and MMCHS_ARG set to 0x00000000 when writing 0x00000000 into MMCHS_CMD register, the host controller performs a 'command completion signal disable' token that is, CMD line held to 0 during 47 cycles followed by a 1. 0x0: The host does not generate a 48-bit response instead of a command. 0x1: The host generates a 48-bit response instead of a command or a command completion signal disable token.</p> | RW | 0 |
| 1 | INIT | <p>Send initialization stream All cards. When this bit is set to 1, and the card is idle, an initialization sequence is sent to the card. An initialization sequence consists of setting the CMD line to 1 during 80 clock cycles. The initialisation sequence is mandatory - but it is not required to do it through this bit - this bit makes it easier. Clock divider (MMCHS_SYSCTL[15:6] CLKD) should be set to ensure that 80 clock periods are greater than 1ms. (see section 9.3, "Power-Up", in the MMC card specification [1], or section 6.4 in the SD card specification [2]). Note: in this mode, there is no command sent to the card and no response is expected 0x0: The host does not send an initialization sequence. 0x1: The host sends an initialization sequence.</p> | RW | 0 |
| 0 | OD | <p>Card open drain mode. Only for MMC cards. This bit must be set to 1 for MMC card commands 1, 2, 3 and 40, and if the MMC card bus is operating in open-drain mode during the response phase to the command sent. Typically, during card identification mode when the card is either in idle, ready or ident state. It is also necessary to set this bit to 1, for a broadcast host response (see Broadcast host response register MMCHS_CON[2] HR) 0x0: No Open Drain 0x1: Open Drain or Broadcast host response</p> | RW | 0 |

| 19 | CCCE | <p>Command CRC check enable This bit must be set to 1 to enable CRC7 check on command response to protect the response against transmission errors on the bus. If an error is detected, it is reported as a command CRC error (MMCHS_STAT[17] CCRC set to 1). Note: The register CCCE cannot be configured for an Auto CMD12, and then CRC check is automatically checked when this command is issued.</p> <p>0x0: CRC7 check disable 0x1: CRC7 check enable</p> | RW | 0 |
| 18 | RESERVED | <p>Reserved. This bit is initialized to zero, and writes to it are ignored.</p> | R | 0 |
| 17:16 | RSP_TYPE | <p>Response type This bits defines the response type of the command</p> <p>0x0: No response 0x1: Response Length 136 bits 0x2: Response Length 48 bits 0x3: Response Length 48 bits with busy after response</p> | RW | 0x0 |
| 15:6 | RESERVED | <p>Reserved. These bits are initialized to zero, and writes to them are ignored.</p> | R | 0x000 |
| 5 | MSBS | <p>Multi/Single block select This bit must be set to 1 for data transfer in case of multi block command. For any others command this bit shall be set to 0.</p> <p>0x0: Single block. If this bit is 0, it is not necessary to set the register MMCHS_BLK[31:16] NBLK. 0x1: Multi block. When Block Count is disabled (MMCHS_CMD[1] BCE is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS is set to 1), the module can perform infinite transfer.</p> | RW | 0 |
| 4 | DDIR | <p>Data transfer Direction Select This bit defines either data transfer will be a read or a write.</p> <p>0x0: Data Write (host to card) 0x1: Data Read (card to host)</p> | RW | 0 |
| 3 | RESERVED | <p>Reserved. These bits are initialized to zero, and writes to them are ignored.</p> | R | 0 |
| 2 | ACEN | <p>Auto CMD12 Enable SDIO does not support this feature. When this bit is set to 1, the host controller issues a CMD12 automatically after the transfer completion of the last block. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop data transfer. In particular, safe commands do not require CMD12.</p> <p>0x0: Auto CMD12 disable 0x1: Auto CMD12 enable or CCS detection enabled.</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 1 | BCE | Block Count Enable Multiple block transfers only. This bit is used to enable the block count register (MMCHS_BLK[31:16] NBLK). When Block Count is disabled (MMCHS_CMD[1] BCE is set to 0) in Multiple block transfers (MMCHS_CMD[5] MSBS is set to 1), the module can perform infinite transfer. 0x0: Block count disabled for infinite transfer. 0x1: Block count enabled for multiple block transfer with known number of blocks | RW | 0 |
| 0 | DE | DMA Enable This bit is used to enable DMA mode for host data access. 0x0: DMA mode disable 0x1: DMA mode enable | RW | 0 |

| Description | <p>Data Register</p> <p>This register is the 32-bit entry point of the buffer for read or write data transfers. The buffer size is 32bits x256(1024 bytes). Bytes within a word are stored and read in little endian format. This buffer can be used as two 512 byte buffers to transfer data efficiently without reducing the throughput.</p> <p>Sequential and contiguous access is necessary to increment the pointer correctly. Random or skipped access is not allowed. In little endian, if the local host accesses this register byte-wise or 16bit-wise, the least significant byte (bits [7:0]) must always be written/read first. The update of the buffer address is done on the most significant byte write for full 32-bit DATA register or on the most significant byte of the last word of block transfer.</p> <p>Example 1: Byte or 16-bit access Mbyteen[3:0]=>0001 (1-byte) = Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1100 (2-bytes) OK Mbyteen[3:0]=>0001 (1-byte) = Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=0100 (1-byte) OK Mbyteen[3:0]=>0001 (1-byte) = Mbyteen[3:0]=0010 (1-byte) => Mbyteen[3:0]=1000 (1-byte) Bad</p> | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:25 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x00 |
| 24 | CLEV | CMD line signal level This status is used to check the CMD line level to recover from errors, and for debugging. The value of this register after reset depends on the CMD line level at that time. Read 0x0: The CMD line level is 0. Read 0x1: The CMD line level is 1. | R | - |
| 23:20 | DLEV | DAT[3:0] line signal level DAT[3] => bit 23 DAT[2] => bit 22 DAT[1] => bit 21 DAT[0] => bit 20 This status is used to check DAT line level to recover from errors, and for debugging. This is especially useful in detecting the busy signal level from DAT[0]. The value of these registers after reset depends on the DAT lines level at that time. | R | 0x- |
| 19 | WP | Write protect switch pin level For SDIO cards only. This bit reflects the write protect input pin (SDWP) level. The value of this register after reset depends on the protect input pin (SDWP) level at that time. Read 0x0: If MMCHS_CON[8] WPP is set to 0 (default), the card is write protected, otherwise the card is not protected. Read 0x1: If MMCHS_CON[8] WPP is set to 0 (default), the card is not write protected, otherwise the card is protected. | R | - |
| 18 | CDPL | Card detect pin level This bit reflects the inverse value of the card detect input pin (SDCD), debouncing is not performed on this bit and bit is valid only when Card State Stable (MMCHS_PSTATE[17] CSS) is set to 1. Use of this bit is limited to testing since it must be debounced by software. The value of this register after reset depends on the card detect input pin (SDCD) level at that time. Read 0x0: The value of the card detect input pin (SDCD) is 1 Read 0x1: The value of the card detect input pin (SDCD) is 0 | R | - |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 17 | CSS | <p>Card State Stable</p> <p>This bit is used for testing. It is set to 1 only when Card Detect Pin Level is stable (MMCHS_PSTATE[18] CDPL). Debouncing is performed on the card detect input pin (SDCD) to detect card stability.</p> <p>This bit is not affected by a software reset.</p> <p>Read 0x0: Reset or Debouncing</p> <p>Read 0x1: No card or card inserted</p> | R | 0 |
| 16 | CINS | <p>Card inserted</p> <p>This bit is the debounced value of the card detect input pin (SDCD).</p> <p>An inactive to active transition of the card detect input pin (SDCD) will generate a card insertion interrupt (MMCHS_STAT[6] CINS).</p> <p>A active to inactive transition of the card detect input pin (SDCD) will generate a card removal interrupt (MMCHS_STAT[7] CREM).</p> <p>This bit is not affected by a software reset.</p> <p>Read 0x0: If MMCHS_CON[7] CDP is set to 0 (default), no card is detected. The card may have been removed from the card slot.</p> <p>If MMCHS_CON[7] CDP is set to 1, the card has been inserted.</p> <p>Read 0x1: If MMCHS_CON[7] CDP is set to 0 (default), the card has been inserted from the card slot.</p> <p>If MMCHS_CON[7] CDP is set to 1, no card is detected. The card may have been removed from the card slot.</p> | R | 0 |
| 15:12 | RESERVED | <p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p> | R | 0x0 |
| 11 | BRE | <p>Buffer read enable</p> <p>This bit is used for non-DMA read transfers.</p> <p>It indicates that a complete block specified by MMCHS_BLK[11:0] BLEN has been written in the buffer and is ready to be read.</p> <p>It is set to 0 when the entire block is read from the buffer.</p> <p>It is set to 1 when a block data is ready in the buffer and generates the Buffer read ready status of interrupt (MMCHS_STAT[5] BRR).</p> <p>Read 0x0: Read BLEN bytes disable</p> <p>Read 0x1: Read BLEN bytes enable. Readable data exists in the buffer.</p> | R | 0 |
| 10 | BWE | <p>Buffer Write enable</p> <p>This status is used for non-DMA write transfers.</p> <p>It indicates if space is available for write data.</p> <p>Read 0x0: There is no room left in the buffer to write BLEN bytes of data.</p> <p>Read 0x1: There is enough space in the buffer to write BLEN bytes of data.</p> | R | 0 |
| 9 | RTA | <p>Read transfer active</p> <p>This status is used for detecting completion of a read transfer. It is set to 1 after the end bit of read command or by activating a continue request (MMCHS_HCTL[17] CR) following a stop at block gap request. This bit is set to 0 when all data have been read by the local host after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the DAT lines.</p> <p>Read 0x1: read data transfer on going.</p> | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 8 | WTA | <p>Write transfer active</p> <p>This status indicates a write transfer active. It is set to 1 after the end bit of write command or by activating a continue request (MMCHS_HCTL[17] CR) following a stop at block gap request. This bit is set to 0 when CRC status has been received after last block or after a stop at block gap request.</p> <p>Read 0x0: No valid data on the DAT lines.</p> <p>Read 0x1: Write data transfer on going.</p> | R | 0 |
| 7:3 | RESERVED | <p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p> | R | 0x00 |
| 2 | DLA | <p>DAT line active</p> <p>This status bit indicates whether one of the DAT line is in use.</p> <p>In the case of read transactions (card to host):</p> <p>This bit is set to 1 after the end bit of read command or by activating continue request MMCHS_HCTL[17] CR. This bit is set to 0 when the host controller received the end bit of the last data block or at the beginning of the read wait mode.</p> <p>In the case of write transactions (host to card):</p> <p>This bit is set to 1 after the end bit of write command or by activating continue request MMCHS_HCTL[17] CR. This bit is set to 0 on the end of busy event for the last block; host controller must wait 8 clock cycles with line not busy to really consider not "busy state" or after the busy block as a result of a stop at gap request.</p> <p>Read 0x0: DAT Line inactive</p> <p>Read 0x1: DAT Line active</p> | R | 0 |
| 1 | DATI | <p>Command inhibit(DAT)</p> <p>This status bit is generated if either DAT line is active (MMCHS_PSTATE[2] DLA) or Read transfer is active (MMCHS_PSTATE[9] RTA) or when a command with busy is issued. This bit prevents the local host to issue a command.</p> <p>A change of this bit from 1 to 0 generates a transfer complete interrupt (MMCHS_STAT[1] TC).</p> <p>Read 0x0: Issuing of command using the DAT lines is allowed</p> <p>Read 0x1: Issuing of command using DAT lines is not allowed</p> | R | 0 |
| 0 | CMDI | <p>Command inhibit(CMD)</p> <p>This status bit indicates that the CMD line is in use. This bit is set to 0 when the most significant byte is written into the command register. This bit is not set when Auto CMD12 is transmitted.</p> <p>This bit is set to 0 in either the following cases:</p> <ul style="list-style-type: none"> - After the end bit of the command response, excepted if there is a command conflict error (MMCHS_STAT[17] CCRC or MMCHS_STAT[18] CEB set to 1) or a Auto CMD12 is not executed (MMCHS_AC12[0] ACNE). - After the end bit of the command without response (MMCHS_CMD[17:16] RSP_TYPE set to "00") <p>In case of a command data error is detected (MMCHS_STAT[16] CTO set to 1), this register is not automatically cleared.</p> <p>Read 0x0: Issuing of command using CMD line is allowed</p> <p>Read 0x1: Issuing of command using CMD line is not allowed</p> | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:28 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 27 | OBWE | Wakeup event enable for 'Out-of-Band' Interrupt. This bit enables wakeup events for 'Out-of-Band' assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP). The write to this register is ignored when MMCHS_CON[14] OBIE is not set. 0x0: Disable wakeup on 'Out-of-Band' Interrupt 0x1: Enable wakeup on 'Out-of-Band' Interrupt | RW | 0 |
| 26 | REM | Wakeup event enable on SD card removal This bit enables wakeup events for card removal assertion. Wakeup is generated if the wakeup feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP). 0x0: Disable wakeup on card removal 0x1: Enable wakeup on card removal | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 25 | INS | Wake-up event enable on SD card insertion This bit enables wake-up events for card insertion assertion. Wakeup is generated if the wake-up feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP). 0x0: Disable wake-up on card insertion 0x1: Enable wake-up on card insertion | RW | 0 |
| 24 | IWE | Wake-up event enable on SD card interrupt This bit enables wake-up events for card interrupt assertion. Wakeup is generated if the wake-up feature is enabled (MMCHS_SYSCONFIG[2] ENAWAKEUP). 0x0: Disable wake-up on card interrupt 0x1: Enable wake-up on card interrupt | RW | 0 |
| 23:20 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 19 | IBG | Interrupt block at gap This bit is valid only in 4-bit mode of SDIO card to enable interrupt detection in the interrupt cycle at block gap for a multiple block transfer. For MMC cards and for SD card this bit should be set to 0. 0x0: Disable interrupt detection at the block gap in 4-bit mode 0x1: Enable interrupt detection at the block gap in 4-bit mode | RW | 0 |
| 18 | RWC | Read wait control The read wait function is optional only for SDIO cards. If the card supports read wait, this bit must be enabled, then requesting a stop at block gap (MMCHS_HCTL[16] SBGR) generates a read wait period after the current end of block. Be careful, if read wait is not supported it may cause a conflict on DAT line. 0x0: Disable Read Wait Control. Suspend/Resume cannot be supported. 0x1: Enable Read Wait Control | RW | 0 |
| 17 | CR | Continue request This bit is used to restart a transaction that was stopped by requesting a stop at block gap (MMCHS_HCTL[16] SBGR). Set this bit to 1 restarts the transfer. The bit is automatically set to 0 by the host controller when transfer has restarted i.e DAT line is active (MMCHS_PSTATE[2] DLA) or transferring data (MMCHS_PSTATE[8] WTA). The Stop at block gap request must be disabled (MMCHS_HCTL[16] SBGR = 0) before setting this bit. 0x0: No affect 0x1: transfer restart | RW | 0 |
| 16 | SBGR | Stop at block gap request This bit is used to stop executing a transaction at the next block gap. The transfer can restart with a continue request (MMCHS_HCTL[17] CR) or during a suspend/resume sequence. In case of read transfer, the card must support read wait control. In case of write transfer, the host driver shall set this bit after all block data written. Until the transfer completion (MMCHS_STAT[1] TC set to 1), the host driver shall leave this bit set to 1. If this bit is set, the local host shall not write to the data register (MMCHS_DATA). 0x0: Transfer mode 0x1: Stop at block gap | RW | 0 |
| 15:12 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 11:9 | SDVS | SD bus voltage select All cards. The host driver should set to these bits to select the voltage level for the card according to the voltage supported by the system (MMCHS_CAPA[26:24]) before starting a transfer. 0x5: 1.8V (Typical) 0x6: 3.0V (Typical) 0x7: 3.3V (Typical) | RW | 0x0 |
| 8 | SDBP | SD bus power Before setting this bit, the host driver shall select the SD bus voltage (MMCHS_HCTL[11:9] SDVS). If the host controller detects the No card state, this bit is automatically set to 0. If the module is power off, a write in the command register (MMCHS_CMD) will not start the transfer. A write to this bit has no effect if the selected SD bus voltage is not supported according to capability register (MMCHS_CAPA[26:24]). 0x0: Power off 0x1: Power on | RW | 0 |
| 7 | CDSS | Card Detect Signal Selection This bit selects source for the card detection. When the source for the card detection is switched, the interrupt should be disabled during the switching period by clearing the Interrupt Status/Signal Enable register in order to mask unexpected interrupt being caused by the glitch. The Interrupt Status/Signal Enable should be disabled during over the period of debouncing. 0x0: SDCD# is selected (for normal use) 0x1: The Card Detect Test Level is selected (for test purpose) | RW | 0 |
| 6 | CDTL | Card Detect Test Level: This bit is enabled while the Card Detect Signal Selection is set to 1 and it indicates card inserted or not. 0x0: No Card 0x1: Card Inserted | RW | 0 |
| 5 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0 |
| 4:3 | DMAS | DMA Select Mode: One of supported DMA modes can be selected. The host driver shall check support of DMA modes by referring the Capabilities register. Use of selected DMA is determined by DMA Enable of the Transfer Mode register. This register is only meaningful when MMCHS_HL_HWINFO[0] MADMA_EN is set to 1. When MMCHS_HL_HWINFO[0] MADMA_EN is set to 0 the bit field is read only and returned value is 0. 0x0: Reserved 0x1: Reserved 0x2: 32-bit Address ADMA2 is selected 0x3: Reserved | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 2 | HSPE | <p>High Speed Enable: Before setting this bit, the Host Driver shall check the High Speed Support in the Capabilities register. If this bit is set to 0 (default), the Host Controller outputs CMD line and DAT lines at the falling edge of the SD Clock. If this bit is set to 1, the Host Controller outputs CMD line and DAT lines at the rising edge of the SD Clock. This bit shall not be set when dual data rate mode is activated in MMCHS_CON[19] DDR.</p> <p>0x0: Normal speed mode 0x1: High speed mode</p> | RW | 0 |
| 1 | DTW | <p>Data transfer width For MMC card, this bit must be set following a valid SWITCH command (CMD6) with the correct value and extend CSD index written in the argument. Prior to this command, the MMC card configuration register (CSD and EXT_CSD) must be verified for compliance with MMC standard specification 4.x (see section 3.6). This register has no effect when the MMC 8-bit mode is selected (register MMCHS_CON[5] DW8 set to 1), For SD/SDIO cards, this bit must be set following a valid SET_BUS_WIDTH command (ACMD6) with the value written in bit 1 of the argument. Prior to this command, the SD card configuration register (SCR) must be verified for the supported bus width by the SD card.</p> <p>0x0: 1-bit Data width (DAT[0] used) 0x1: 4-bit Data width (DAT[3:0] used)</p> | RW | 0 |
| 0 | LED | <p>Reserved bit. LED control feature is not supported This bit is initialized to zero, and writes to it are ignored.</p> | R | 0 |

|-------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:27 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x00 |
| 26 | SRD | Software reset for DAT line. This bit is set to 1 for reset and released to 0 when completed. For more information about SRD bit manipulation, see Section 24.5.1.2.1.2.1, DATA Lines Reset Procedure . DAT finite state machine in both clock domain are also reset. The following registers are cleared by MMCHS_SYSCTL[26] SRD: - MMCHS_DATA - MMCHS_PSTATE[11] BRE, MMCHS_PSTATE[10] BWE, MMCHS_PSTATE[9] RTA, MMCHS_PSTATE[8] WTA, MMCHS_PSTATE[2] DLA, MMCHS_PSTATE[1] DAT1 - MMCHS_HCTL: SBGR and CR - MMCHS_STAT: MMCHS_STAT[5] BRR, MMCHS_STAT[4] BWR, MMCHS_STAT[2] BGE and MMCHS_STAT[1] TC Interconnect and MMC buffer data management is reinitialized. 0x0: Reset completed 0x1: Software reset for DAT line | RW | 0 |
| 25 | SRC | Software reset for CMD line For more information about SRC bit manipulation, see Section 24.5.1.2.1.1.1, CMD Line Reset Procedure . This bit is set to 1 for reset and released to 0 when completed. CMD finite state-machine in both clock domain are also reset. The following registers are cleared by MMCHS_SYSCTL[25] SRC: - MMCHS_PSTATE[0] CMDI - MMCHS_STAT[0] CC Interconnect and MMC command status management is reinitialized. 0x0: Reset completed 0x1: Software reset for CMD line | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 24 | SRA | Software reset for all This bit is set to 1 for reset, and released to 0 when completed. This reset affects the entire host controller except for the card detection circuit and capabilities registers. 0x0: Reset completed 0x1: Software reset for all the design | RW | 0 |
| 23:20 | RESERVED | Reserved. These bits are initialized to 0, and writes to them are ignored. | R | 0x0 |
| 19:16 | DTO | Data timeout counter value and busy timeout. This value determines the interval by which DAT lines timeouts are detected. The host driver needs to set this bit field based on - the maximum read access time (NAC) (Refer to the SD Specification Part1 Physical Layer), - the data read access time values (TAAC and NSAC) in the card specific data register (CSD) of the card, - the timeout clock base frequency (MMCHS_CAPA[5:0] TCF). If the card does not respond within the specified number of cycles, a data timeout error occurs (MMCHS_STAT[20] DTO). The MMCHS_SYSCTL[19:16] DTO register is also used to check busy duration, to generate busy timeout for commands with busy response or for busy programming during a write command. Timeout on CRC status is generated if no CRC token is present after a block write. 0x0: $TCF \times 2^{13}$ 0x1: $TCF \times 2^{14}$ 0xE: $TCF \times 2^{27}$ 0xF: Reserved | RW | 0x0 |
| 15:6 | CLKD | Clock frequency select These bits define the ratio between MMCi_FCLK and the output clock frequency on the CLK pin of either the memory card (MMC, SD or SDIO). 0x0: MMCi_FCLK bypass 0x1: MMCi_FCLK bypass 0x2: MMCi_FCLK / 2 0x3: MMCi_FCLK / 3 0x3FF: MMCi_FCLK / 1023 | RW | 0x000 |
| 5:3 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 2 | CEN | Clock enable This bit controls if the clock is provided to the card or not. 0x0: The clock is not provided to the card . Clock frequency can be changed . 0x1: The clock is provided to the card and can be automatically gated when MMCHS_SYSCONFIG[0] AUTOIDLE is set to 1 (default value) . The host driver shall wait to set this bit to 1 until the Internal clock is stable (MMCHS_SYSCTL[1] ICS). | RW | 0 |
| 1 | ICS | Internal clock stable (status) This bit indicates either the internal clock is stable or not. Read 0x0: The internal clock is not stable. Read 0x1: The internal clock is stable after enabling the clock (MMCHS_SYSCTL[1] ICE) or after changing the clock ratio (MMCHS_SYSCTL[15:6] CLKD). | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 0 | ICE | Internal clock enable This register controls the internal clock activity. In very low power state, the internal clock is stopped. Note: The activity of the debounce clock (used for wakeup events) and the interface clock (used for reads and writes to the module register map) are not affected by this register. 0x0: The internal clock is stopped (very low power state). 0x1: The internal clock oscillates and can be automatically gated when MMCHS_SYSCONFIG[0] AUTOIDLE is set to 1 (default value) . | RW | 0 |

| RESERVED | BADA | CERR | RESERVED | ADMAE | ACE | CLE | DEB | DCRC | DTO | CIE | CEB | CCRC | CTO | ERRI | RESERVED | BSR | OBI | CIRQ | CREM | CINS | BRR | BWR | DMA | BGE | TC | CC | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:30 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 29 | BADA | Bad access to data space This bit is set automatically to indicate a bad access to buffer when not allowed: -This bit is set during a read access to the data register (MMCHS_DATA) while buffer reads are not allowed (MMCHS_PSTATE [11] BRE = 0) -This bit is set during a write access to the data register (MMCHS_DATA) while buffer writes are not allowed (MMCHS_PSTATE [10] BWE = 0) Write 0x0: Status bit unchanged Read 0x0: No Interrupt. Read 0x1: Bad Access Write 0x1: Status is cleared | RW | 0 |
| 28 | CERR | Card error This bit is set automatically when there is at least one error in a response of type R1, R1b, R6, R5 or R5b. Only bits referenced as type E(error) in status field in the response can set a card status error. An error bit in the response is flagged only if corresponding bit in card status response error MMCHS_CSRE is set. There is no card error detection for autoCMD12 command. The host driver shall read MMCHS_RSP76 register to detect error bits in the command response. Write 0x0: Status bit unchanged Read 0x0: No Error Write 0x1: Status is cleared Read 0x1: Card error | RW | 0 |
| 27:26 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 25 | ADMAE | ADMA Error: This bit is set when the Host Controller detects errors during ADMA based data transfer. The state of the ADMA at an error occurrence is saved in the ADMA Error Status Register. In addition, the Host Controller generates this interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. ADMA Error State in the ADMA Error Status indicates that an error occurs in ST_FDS state. The Host Driver may find that Valid bit is not set at the error descriptor. Write 0x0: Status bit unchanged Read 0x0: No Interrupt. Write 0x1: Status is cleared Read 0x1: ADMA error | RW | 0 |
| 24 | ACE | Auto CMD12 error This bit is set automatically when one of the bits in Auto CMD12 Error status register has changed from 0 to 1. Write 0x0: Status bit unchanged Read 0x0: No Error. Read 0x1: AutoCMD12 error Write 0x1: Status is cleared | RW | 0 |
| 23 | CLE | Reserved. Current limit error is not supported. These bits are initialized to zero, and writes to them are ignored. | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 22 | DEB | <p>Data End Bit error</p> <p>This bit is set automatically when detecting a 0 at the end bit position of read data on DAT line or at the end position of the CRC status in write mode.</p> <p>Read 0x0: No Error</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Data end bit error</p> | RW | 0 |
| 21 | DCRC | <p>Data CRC Error</p> <p>This bit is set automatically when there is a CRC16 error in the data phase response following a block read command or if there is a 3-bit CRC status different of a position "010" token during a block write command.</p> <p>Read 0x0: No Error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Data CRC error</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 20 | DTO | <p>Data timeout error</p> <p>This bit is set automatically according to the following conditions:</p> <ul style="list-style-type: none"> - busy timeout for R1b, R5b response type - busy timeout after write CRC status - write CRC status timeout - read data timeout <p>Read 0x0: No error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Time out</p> | RW | 0 |
| 19 | CIE | <p>Command index error</p> <p>This bit is set automatically when response index differs from corresponding command index previously emitted. It depends on the enable in MMCHS_CMD[20] CICE register.</p> <p>Read 0x0: No error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Command index error</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 18 | CEB | <p>Command end bit error</p> <p>This bit is set automatically when detecting a 0 at the end bit position of a command response.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No error.</p> <p>Read 0x1: Command end bit error</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 17 | CCRC | <p>Command CRC Error</p> <p>This bit is set automatically when there is a CRC7 error in the command response depending on the enable in MMCHS_CMD[19] CCCE register.</p> <p>Read 0x0: No Error.</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Command CRC error</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 16 | CTO | <p>Command Timeout Error</p> <p>This bit is set automatically when no response is received within 64 clock cycles from the end bit of the command. For commands that reply within 5 clock cycles - the timeout is still detected at 64 clock cycles.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No error</p> <p>Read 0x1: Time Out</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 15 | ERRI | <p>Error Interrupt</p> <p>If any of the bits in the Error Interrupt Status register (MMCHS_STAT[24:15]) are set, then this bit is set to 1. Therefore the host driver can efficiently test for an error by checking this bit first. Writes to this bit are ignored.</p> <p>Read 0x0: No Interrupt.</p> <p>Read 0x1: Error interrupt event(s) occurred</p> | R | 0 |
| 14:11 | RESERVED | <p>Reserved.</p> <p>These bits are initialized to zero, and writes to them are ignored.</p> | R | 0x0 |
| 10 | BSR | <p>Boot status received interrupt</p> <p>This bit is set automatically when MMCHS_CON[18] BOOT_CF0 is set 0x0 or 0x1 and a boot status is received on DAT[0] line. This interrupt is only useful for MMC card.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No Interrupt.</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Boot status received interrupt.</p> | RW | 0 |
| 9 | OBI | <p>Out-Of-Band interrupt</p> <p>This bit is set automatically when MMCHS_CON[14] OBIE is set and an Out-of-Band interrupt occurs on OBI pin.</p> <p>The interrupt detection depends on polarity controlled by MMCHS_CON[13] OBIP.</p> <p>This interrupt is only useful for MMC card.</p> <p>The Out-of-Band interrupt signal is a system specific feature for future use, this signal is not required for existing specification implementation.</p> <p>Read 0x0: No Out-Of-Band interrupt.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Interrupt Out-Of-Band occurs</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 8 | CIRQ | <p>Card interrupt</p> <p>This bit is only used for SD and SDIO and CE-ATA cards. In 1-bit mode, interrupt source is asynchronous (can be a source of asynchronous wakeup). In 4-bit mode, interrupt source is sampled during the interrupt cycle.</p> <p>In CE-ATA mode, interrupt source is detected when the card drives CMD line to zero during one cycle after data transmission end. All modes above are fully exclusive.</p> <p>The controller interrupt must be clear by setting MMCHS_IE[8] CIRQ_ENABLE to 0, then the host driver must start the interrupt service with card (clearing card interrupt status) to remove card interrupt source. Otherwise the Controller interrupt will be reasserted as soon as MMCHS_IE[8] CIRQ_ENABLE is set to 1. Writes to this bit are ignored.</p> <p>Read 0x0: No card interrupt</p> <p>Read 0x1: Generate card interrupt</p> | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 7 | CREM | <p>Card removal</p> <p>This bit is set automatically when MMCHS_PSTATE[16] CINS changes from 1 to 0. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[16] CINS).</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: Card state stable or Debouncing</p> <p>Read 0x1: Card removed</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 6 | CINS | <p>Card insertion</p> <p>This bit is set automatically when MMCHS_PSTATE[16] changes from 0 to 1. A clear of this bit doesn't affect Card inserted present state (MMCHS_PSTATE[16] CINS).</p> <p>Read 0x0: Card state stable or debouncing</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Card inserted</p> | RW | 0 |
| 5 | BRR | <p>Buffer read ready</p> <p>This bit is set automatically during a read operation to the card (see class 2 - block oriented read commands) when one block specified by MMCHS_BLK[11:0] BLEN is completely written in the buffer. It indicates that the memory card has filled out the buffer and that the local host needs to empty the buffer by reading it. Note: If the DMA receive-mode is enabled, this bit is never set; instead a DMA receive request to the main DMA controller of the system is generated.</p> <p>Read 0x0: Not Ready to read buffer</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x1: Ready to read buffer</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 4 | BWR | <p>Buffer write ready</p> <p>This bit is set automatically during a write operation to the card (see class 4 - block oriented write command) when the host can write a complete block as specified by MMCHS_BLK[11:0] BLEN. It indicates that the memory card has emptied one block from the buffer and that the local host is able to write one block of data into the buffer. Note: If the DMA transmit mode is enabled, this bit is never set; instead, a DMA transmit request to the main DMA controller of the system is generated.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: Not Ready to write buffer</p> <p>Read 0x1: Ready to write buffer</p> <p>Write 0x1: Status is cleared</p> | RW | 0 |
| 3 | DMA | <p>DMA interrupt :</p> <p>This status is set when an interrupt is required in the ADMA instruction and after the data transfer completion.</p> <p>Read 0x0: Dma interrupt detected</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: No dma interrupt</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 2 | BGE | <p>Block gap event</p> <p>When a stop at block gap is requested (MMCHS_HCTL[16] SBGR), this bit is automatically set when transaction is stopped at the block gap during a read or write operation.</p> <p>This event does not occur when the stop at block gap is requested on the last block.</p> <p>In read mode, a 1-to-0 transition of the DAT Line active status (MMCHS_PSTATE[2] DLA) between data blocks generates a Block gap event interrupt.</p> <p>Read 0x0: No block gap event</p> <p>Write 0x0: Status bit unchanged</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Transaction stopped at block gap</p> | RW | 0 |
| 1 | TC | <p>Transfer completed</p> <p>This bit is always set when a read/write transfer is completed or between two blocks when the transfer is stopped due to a stop at block gap request (MMCHS_HCTL[16] SBGR).</p> <p>In Read mode:</p> <p>This bit is automatically set on completion of a read transfer (MMCHS_PSTATE[9] RTA).</p> <p>In write mode:</p> <p>This bit is set automatically on completion of the DAT line use (MMCHS_PSTATE[2] DLA).</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No transfer complete</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Data transfer complete</p> | RW | 0 |
| 0 | CC | <p>Command complete</p> <p>This bit is set when a 1-to-0 transition occurs in the register command inhibit (MMCHS_PSTATE[0] CMDI)</p> <p>If the command is a type for which no response is expected, then the command complete interrupt is generated at the end of the command.</p> <p>A command timeout error (MMCHS_STAT[16] CTO) has higher priority than command complete (MMCHS_STAT[0] CC).</p> <p>If a response is expected but none is received, then a command timeout error is detected and signaled instead of the command complete interrupt.</p> <p>Write 0x0: Status bit unchanged</p> <p>Read 0x0: No Command complete</p> <p>Write 0x1: Status is cleared</p> <p>Read 0x1: Command complete</p> | RW | 0 |

| Description | Auto CMD12 Error Status Register The host driver may determine which of the errors cases related to Auto CMD12 has occurred by checking this MMCHS_AC12 register when an Auto CMD12 Error interrupt occurs. This register is valid only when Auto CMD12 is enabled (MMCHS_CMD [2] ACEN) and Auto CMD12Error (MMCHS_STAT [24] ACE) is set to 1. Note: These bits are automatically reset when starting a new adtc command with data. | | |

|-------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:29 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 28 | BIT64 | 64-bit system bus support: Setting 1 to this bit indicates that the Host Controller supports 64-bit address descriptor mode and is connected to 64-bit address system bus. Read 0x0: 32-bit system bus address Read 0x1: 64-bit system bus address | R | 0 |
| 27 | RESERVED | | R | 0 |
| 26 | VS18 | Voltage support 1.8 V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal) Write 0x0: 1.8 V not supported Read 0x0: 1.8 V not supported Read 0x1: 1.8 V supported Write 0x1: 1.8 V supported | RW | 0 |
| 25 | VS30 | Voltage support 3.0 V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal) Read 0x0: 3.0 V not supported Write 0x0: 3.0 V not supported Write 0x1: 3.0 V supported Read 0x1: 3.0 V supported | RW | 0 |
| 24 | VS33 | Voltage support 3.3 V Initialization of this register (via a write access to this register) depends on the system capabilities. The host driver shall not modify this register after the initialization. This register is only reinitialized by a hard reset (via RESETN signal) Read 0x0: 3.3 V not supported Write 0x0: 3.3 V not supported Write 0x1: 3.3 V supported Read 0x1: 3.3 V supported | RW | 0 |
| 23 | SRS | Suspend/Resume support (SDIO cards only) This bit indicates whether the host controller supports suspend/resume functionality. Read 0x0: The host controller does not suspend/resume functionality. Read 0x1: The host controller supports suspend/resume functionality. | R | 1 |
| 22 | DS | DMA support This bit indicates that the Host Controller is able to use DMA to transfer data between system memory and the Host Controller directly. Read 0x0: DMA not supported Read 0x1: DMA supported | R | 1 |
| 21 | HSS | High-speed support This bit indicates that the host controller supports high-speed operations and can supply an up-to maximum card frequency. Read 0x0: High speed not supported Read 0x1: High speed supported | R | 1 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 20 | RESERVED | Reserved. This bit is initialized to zero, and writes to it are ignored. | R | 0 |
| 19 | AD2S | ADMA2 support: This bit indicates whether the host controller is capable of using ADMA2. It depends on setting of generic parameter MMCHS_HL_HWINFO[0] MADMA_EN Read 0x0: ADMA2 not supported Read 0x1: ADMA2 supported | R | 1 |
| 18 | RESERVED | Reserved. This bit is initialized to zero, and writes to it are ignored. | R | 0 |
| 17:16 | MBL | Maximum block length This value indicates the maximum block size that the host driver can read and write to the buffer in the host controller. This value depends on definition of generic parameter with a max value of 2048 bytes. The host controller supports 512- byte and 1024-byte block transfers. Read 0x0: 512 bytes Read 0x1: 1024 bytes Read 0x2: 2048 bytes | R | 0x1 |
| 15:14 | RESERVED | Reserved. These bits are initialized to zero, and writes to them are ignored. | R | 0x0 |
| 13:8 | BCF | Base clock frequency for clock provided to the card. Read 0x0: The value indicating the base (maximum) frequency for the output clock provided to the card is system dependent and is not available in this register. Get the information via another method. | R | 0x00 |
| 7 | TCU | Timeout clock unit This bit shows the unit of base clock frequency used to detect Data Timeout Error (MMCHS_STAT[20] DTO). Read 0x0: kHz Read 0x1: MHz | R | 1 |
| 6 | RESERVED | Reserved. This bit is initialized to zero, and writes to it are ignored. | R | 0 |
| 5:0 | TCF | Timeout clock frequency The timeout clock frequency is used to detect Data Timeout Error (MMCHS_STAT[20] DTO). Read 0x0: The timeout clock frequency depends on the frequency of the clock provided to the card. The value of the timeout clock frequency is not available in this register. | R | 0x00 |

| Physical Address | 0x4809 C254 0x480B 4254 | Instance | MMCHS1 MMCHS2 |
| Description | <p>ADMA Error Status Register</p> <p>When ADMA Error Interrupt is occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address Register holds the address around the error descriptor. For recovering the error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:</p> <p>ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address</p> <p>ST_FDS: Current location set in the ADMA System Address register is the error descriptor address</p> <p>ST_CADR: This state is never set because do not generate ADMA error in this state.</p> <p>ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address</p> <p>In case of write operation, the Host Driver should use ACMD22 to get the number of written block rather than using this information, since unwritten data may exist in the Host Controller. The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) at the ST_FDS state. In this case, ADMA Error State indicates that an error occurs at ST_FDS state. The Host Driver may find that the Valid bit is not set in the error descriptor.</p> | | |

General-Purpose Interface

This chapter describes the general-purpose interface on the device.

| Topic | Page |
|--------------------------------------------------------------------|-------------|
| 25.1 General-Purpose Interface Overview | 5519 |
| 25.2 General-Purpose Interface Environment | 5522 |
| 25.3 General-Purpose Interface Integration | 5527 |

| 25.5 General-Purpose Interface Programming Guide | 5547 |
| 25.6 General-Purpose Interface Register Manual | 5549 |

25.1 General-Purpose Interface Overview

The general-purpose interface combines six general-purpose input/output (GPIO) banks.

Each GPIO module provides 32 dedicated general-purpose pins with input and output capabilities; thus, the general-purpose interface supports up to 192 (6 × 32) pins.

These pins can be configured for the following applications:

- Data input (capture)/output (drive)
- Keyboard interface with a debounce cell
- Interrupt generation in active mode upon the detection of external events. Detected events are processed by two parallel independent interrupt-generation submodules to support biprocessor operations.
- Wake-up request generation in idle mode upon the detection of external events

These modules do not include pad control (pullup/pulldown control, open-drain feature). For more information, see [Section 18.4.8](#), *Pad Functional Multiplexing and Configuration*, in [Chapter 18](#), *Control Module*.

[Figure 25-1](#) is an overview of the general-purpose interface.

Figure 25-1. General-Purpose Interface Overview

The GPIOs include the following global features:

- Synchronous interrupt requests in active mode from each channel are processed by two identical interrupt generation submodules used independently by the digital signal processor (DSP) and microprocessor unit (MPU) Cortex™-A9 and Cortex™-M3 subsystems. One of these interrupts is mapped on the DSP subsystem interrupt controller (INTC) and the other on the MPU Cortex-A9 and Cortex-M3 subsystem INTCs.
- Asynchronous wake-up requests in idle mode from input channels are merged together to issue one wake-up signal per GPIO.
- Data input (capture)/output (drive)
- Power management support

The general-purpose interface has 12 interrupt lines (two interrupt lines per each GPIO instance).

Each GPIO produces a wake-up request signal to the power, reset, and clock management (PRCM) module.

Each channel in the GPIOs has the following features:

- The GPIOi.GPIO_OE register controls the output capability for each pin.

- The output line level reflects the value written in the GPIOi.GPIO_DATAOUT register through the L4 interconnect.
- The input line can be fed to the GPIO through an optional and configurable debounce cell. (Because the debouncing time value is global for all ports of one GPIO, up to five different debouncing time values are possible.)
- The input line value is sampled into the GPIOi.GPIO_DATAIN register and can be read through the L4 interconnect.
- In active mode, the input line can be used through level and edge detectors to trigger synchronous interrupts. The edge (rising, falling, or both) or the level used (logical 0, logical 1, or both) can be configured.
- In idle mode, the input line can be used to activate the asynchronous wake-up request (on edge detection: rising edge, falling edge, or both).

The module provides an alternative to the atomic test and set operations for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQSTATUS_SET_0
- GPIOi.GPIO_IRQSTATUS_SET_1
- GPIOi.GPIO_IRQSTATUS_CLR_0
- GPIOi.GPIO_IRQSTATUS_CLR_1

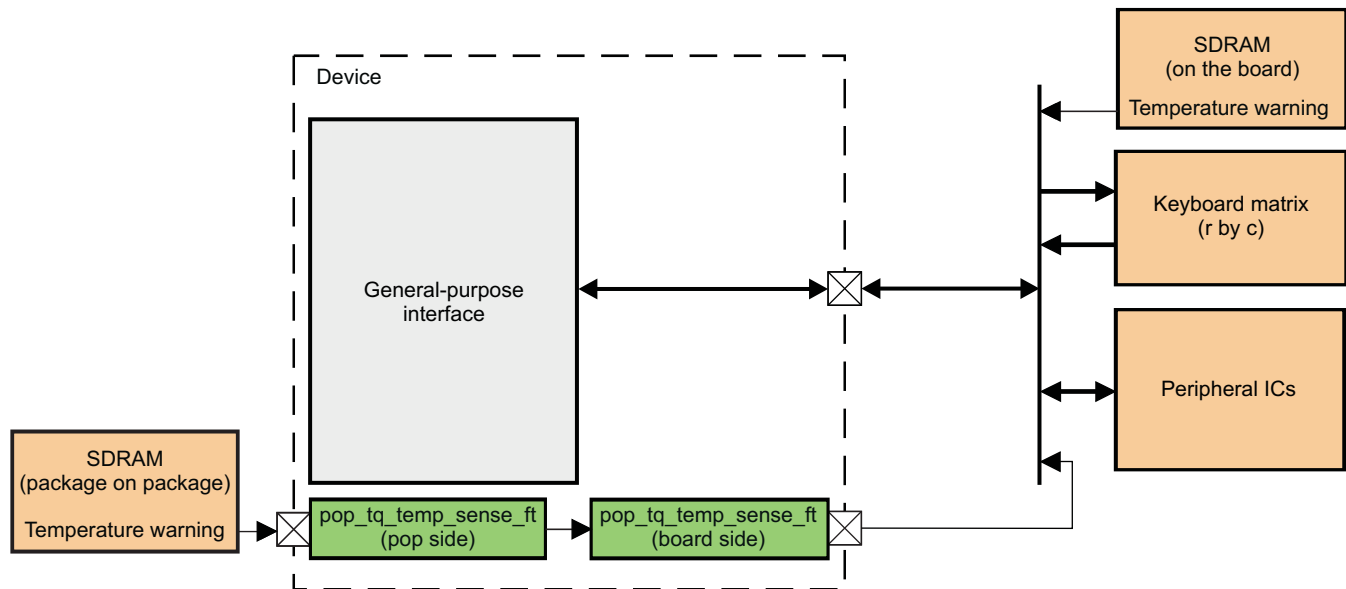

For these registers, the modules implement the set-and-clear protocol register update (see [Section 25.4.9, General-Purpose Interface Set-and-Clear Protocol](#)).

25.2 General-Purpose Interface Environment

The general-purpose interface combines six GPIO modules for a flexible, user-programmable, GPIO controller. The general-purpose interface implements functions that are not implemented with the dedicated controllers in the device and require simple input and/or output software-controlled signals. The general-purpose interface allows a variety of custom connections and expands the I/O capabilities of the system to the real world.

Figure 25-2 shows a typical application using the general-purpose interface.

Figure 25-2. General-Purpose Interface Typical Application

gpio-002

NOTE: Most memories provide a temperature sensor to control the autorefresh duty cycle. The device monitors the temperature of the external memory using the `pop_tq_temp_sense_ft` ball and a GPIO input. To do this, `pop_tq_temp_sense_ft` is connected to a GPIO through the customer board. This feature is application-dependent.

CAUTION

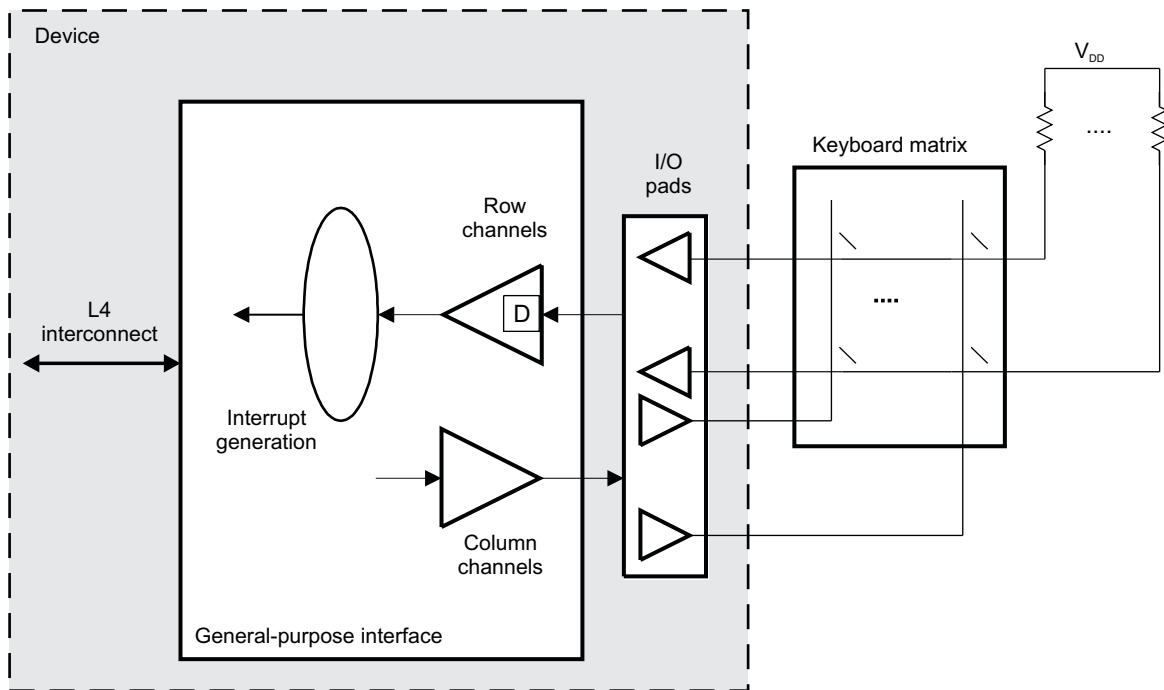

Because of buffer strength, an external serial resistor must be connected to the balls where `gpio_120` through `gpio_129` are muxed with MMC signals.

The general-purpose interface can physically connect the device to a keyboard matrix and peripheral integrated circuits (ICs).

25.2.1 General-Purpose Interface as a Keyboard Interface

The general-purpose interface can be used as a keyboard interface. Channels can be dedicated based on the keyboard matrix ($r \times c$). Figure 25-3 shows row channels configured as inputs with the input debounce feature enabled. The row channels are driven high with an external pullup. Column channels are configured as outputs and drive a low level.

Figure 25-3. General-Purpose Interface Used as a Keyboard Interface

gpio-003

When a keyboard matrix key is pressed, the corresponding row and column lines are shorted together and a low level is driven on the corresponding row channel. This generates an interrupt based on the proper configuration (see Section 25.4.6, *Interrupt and Wake-Up Requests*).

When the keyboard interrupt is received, the processor (MPU and/or DSP subsystem) can disable the keyboard interrupt and scan the column channels for the key coordinates.

- The scanning sequence has as many states as column channels: For each step in the sequence, the processor drives one column channel low and the others high.
- The processor reads the values of the row channels and thus detects which keys in the column are pressed.

At the end of the scanning sequence, the processor establishes which keys are pressed. The keyboard interface can then be reconfigured in the interrupt waiting state.

25.2.2 General-Purpose Interface Signals

Table 25-1 describes the module signals.

Table 25-1. I/O Description

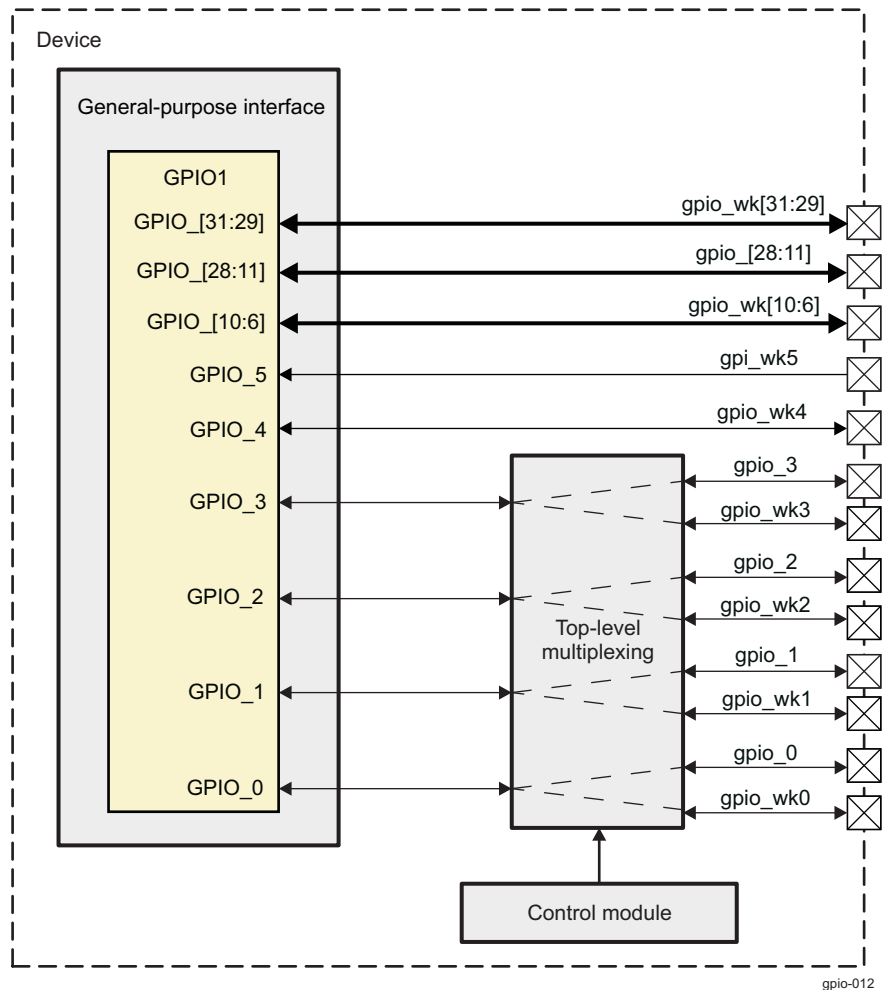

| Signal | I/O ⁽¹⁾ | Description | Reset Value |
|---------------|--------------------|----------------------------------------------------------------------------|-------------|
| gpio_[1:0] | I/O | GPIO | HiZ |
| gpio_wk[1:0] | I/O | GPIO (direct wake-up path). Shares the same GPIO channels with gpio_[1:0]. | HiZ |
| gpio_[3:2] | I/O | GPIO | HiZ |
| gpio_wk[3:2] | I/O | GPIO (direct wake-up path). Shares the same GPIO channels with gpio_[3:2]. | HiZ |
| gpio_wk4 | I/O | GPIO (direct wake-up path) | HiZ |
| gpi_wk5 | I | GPIO input only (direct wake-up path) | HiZ |
| gpio_wk[10:6] | I/O | GPIO (direct wake-up path) | HiZ |
| gpio_[28:11] | I/O | GPIO | HiZ |

⁽¹⁾ I = Input; O = Output

Table 25-1. I/O Description (continued)

| Signal | I/O ⁽¹⁾ | Description | Reset Value |
|----------------|--------------------|----------------------------|-------------|
| gpio_wk[31:29] | I/O | GPIO (direct wake-up path) | HiZ |
| gpio_[56:32] | I/O | GPIO | HiZ |
| gpio_[66:59] | I/O | GPIO | HiZ |
| gpi_[80:67] | I | GPIO inputs only | HiZ |
| gpio_[178:81] | I/O | GPIO | HiZ |
| gpio_[191:181] | I/O | GPIO | HiZ |

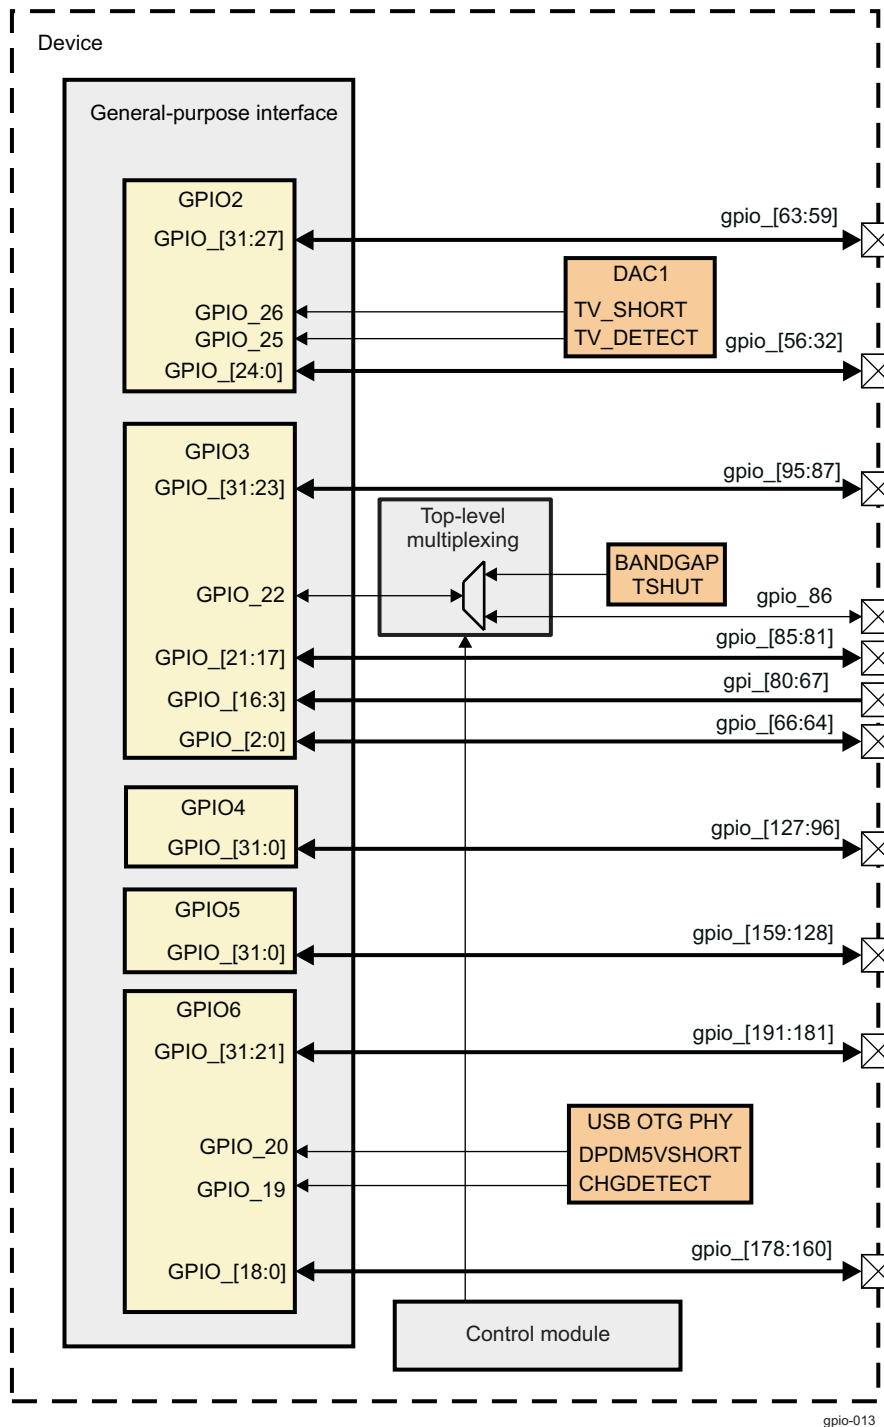

Figure 25-4 shows the signal connections of GPIO1.

Figure 25-4. GPIO1 Signal Connections

- NOTE:** Users must not use a GPIO channel through two device pads simultaneously. Channels that can be mapped on two different device pads are:
- GPIO[3:0] of the GPIO1 module (signals gpio_[3:0] or gpio_wk[3:0]; each can be routed to a different device pad). See [Figure 25-4](#).
 - GPIO[8:4] of the GPIO4 module (signals gpio_[104:100]; each can be routed to two different device pads)

Therefore, appropriate configuration must be done through the pad configuration registers. See [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

[Figure 25-5](#) shows the signal connections of GPIO2 through GPIO6.

Figure 25-5. GPIO2 Through GPIO6 Signal Connections

NOTE: The GPIO_22 channel of the GPIO3 module receives a thermal shutdown (TSHUT) signal from the BANDGAP module whenever pad mux mode is not set to 3 (gpio_86 signal selected). See [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

NOTE: For more information about the signals and channel descriptions of GPIO1 through GPIO6, see [Section 25.4.7, General-Purpose Interface Channels Description](#).

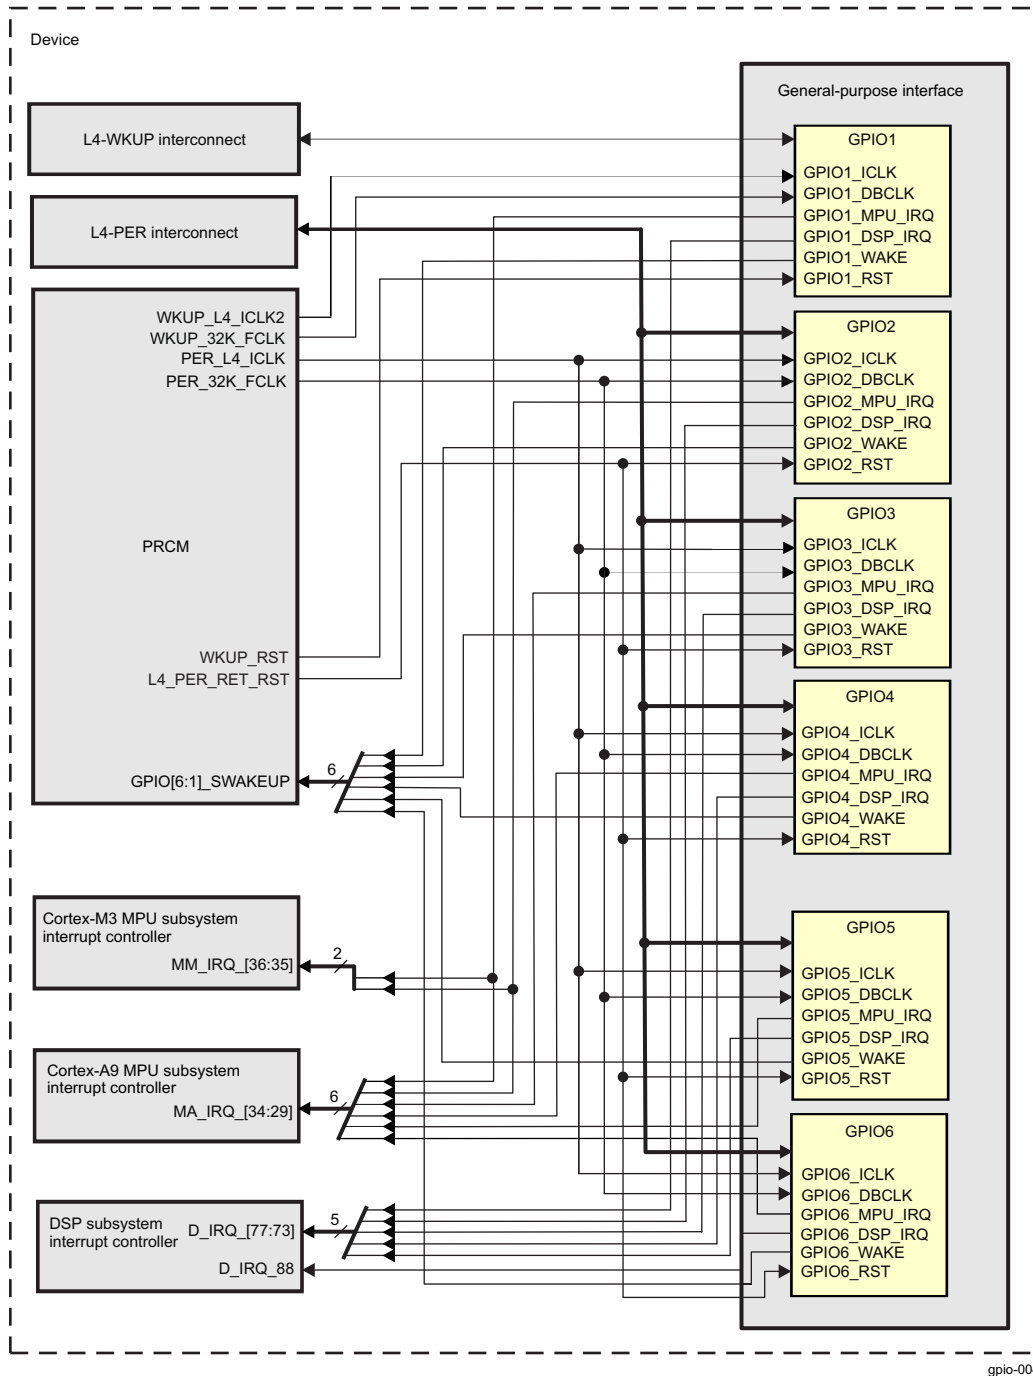

NOTE: For more information about GPIO signal multiplexing, see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#).

25.3 General-Purpose Interface Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

[Figure 25-6](#) shows this module integration.

Figure 25-6. GPIO Integration

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 25-2](#) through [Table 25-4](#) summarize the integration of the module in the device.

Table 25-2. Integration Attributes

| Module Instance | Attributes | |
|-------------------------|--------------|--------------|
| | Power Domain | Interconnect |

| GPIO6 | GPIO6_MPU_IRQ | MA_IRQ_34 | Cortex-A9 | An interrupt to MPU subsystem INTC (first interrupt) |

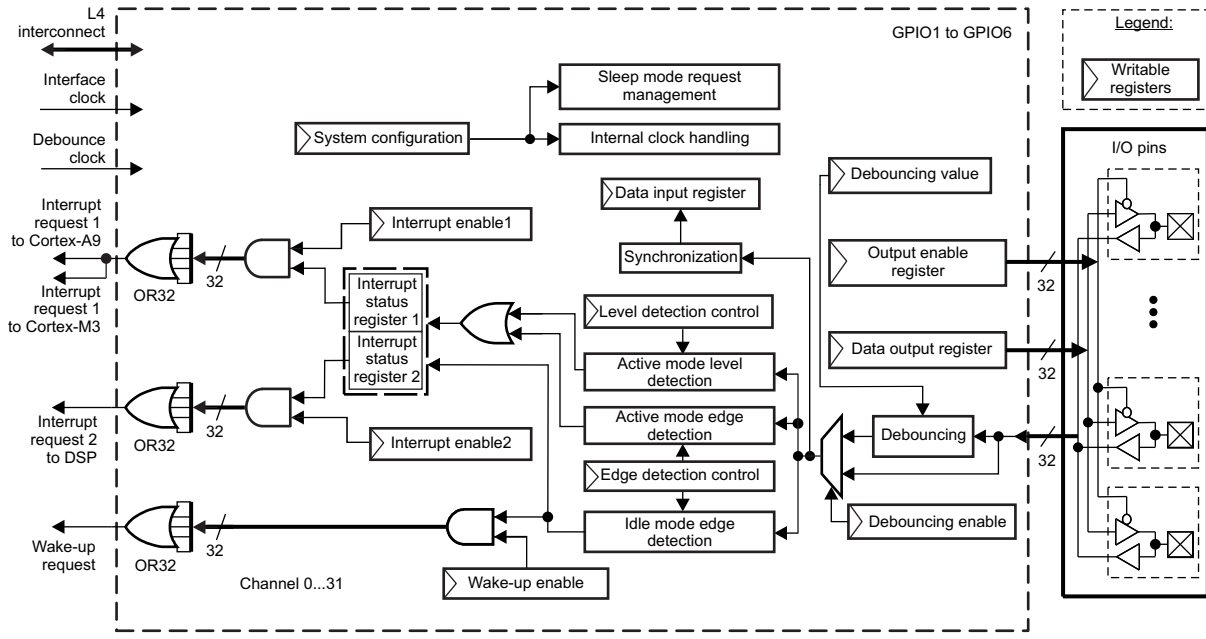

NOTE: For a description of interrupt source, see [Section 25.4.6](#), *General-Purpose Interface Interrupt and Wake-Up Requests*.

25.4 General-Purpose Interface Functional Description

25.4.1 General-Purpose Interface Block Diagram

Figure 25-7 shows the general-purpose interface.

Figure 25-7. General-Purpose Interface Description

gpio-005

Figure 25-7 shows the details of the GPIOs in the general-purpose interface block diagram, including their configuration registers and main functional paths:

- The synchronous path (for active mode operation) used to generate a synchronous interrupt request on expected event detection on any input GPIO. Synchronous interrupt request lines 1 and 2 are active based on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, and GPIOi.GPIO_IRQSTATUS_CLR_1). See Figure 25-8.

Figure 25-8. Synchronous Path

gpio-006

- The asynchronous path (for idle mode operation) used to generate an asynchronous wake-up request on the expected edge detection on any input GPIO. The asynchronous wake-up request line is active based on the wake-up-enable register. See Figure 25-9.

Figure 25-9. Asynchronous Path

- The blocks handling the internal clock (clock gating) and managing the sleep mode request/acknowledge protocol (enabling the synchronous path in active mode and the asynchronous path in idle mode)

25.4.2 General-Purpose Interface Interrupt and Wake-Up Features

25.4.2.1 Synchronous Path: Interrupt Request Generation

The general-purpose interface has 12 interrupt lines (two interrupt lines per each GPIO instance). The 12 interrupt signals are GPIOi_MPU_IRQ (used by the MPU) and GPIOi_DSP_IRQ (used by the DSP subsystem), where $i = 1, 2, 3, 4, 5, \text{ or } 6$.

Synchronous interrupt requests from each channel are processed by two identical interrupt generation submodules used independently by the DSP subsystem on one side and by the MPU subsystems on the other side. Each submodule controls its own synchronous interrupt request line and has its own interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0, or GPIOi.GPIO_IRQSTATUS_CLR_1) and interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1). The interrupt-enable register selects the channel(s) considered for the interrupt request generation, and the interrupt status register determines which channel(s) activate the interrupt request. Event detection on GPIO channels is reflected in the interrupt status registers independent of the content of the interrupt-enable registers.

In active mode, when the GPIO configuration registers are set to enable the interrupt generation (see [Section 25.4.6, General-Purpose Interface Interrupt and Wake-Up Requests](#)), a synchronous path samples the transitions and levels on the input GPIO with the internally gated interface clock (see [Section 25.4.5.2.4, Module Power Saving](#)). When an event matches the programmed settings (see [Section 25.4.6, General-Purpose Interface Interrupt and Wake-Up Requests](#)), the corresponding bit in the interrupt status register is set to 1 and, on the following interface clock cycle, interrupt lines 1 and/or 2 are activated (depending on the interrupt-enable registers).

Because of the sampling operation, the minimum pulse width on the input GPIO to trigger a synchronous interrupt request is two times the internally gated interface clock period (the internally gated interface clock period equals N times the interface clock period (see [Section 25.4.5.2.4, Module Power Saving](#)). This minimum pulse width must be met before and after any expected level transition detection. Level detection requires the selected level to be stable for at least two times the internally gated interface clock period to trigger a synchronous interrupt.

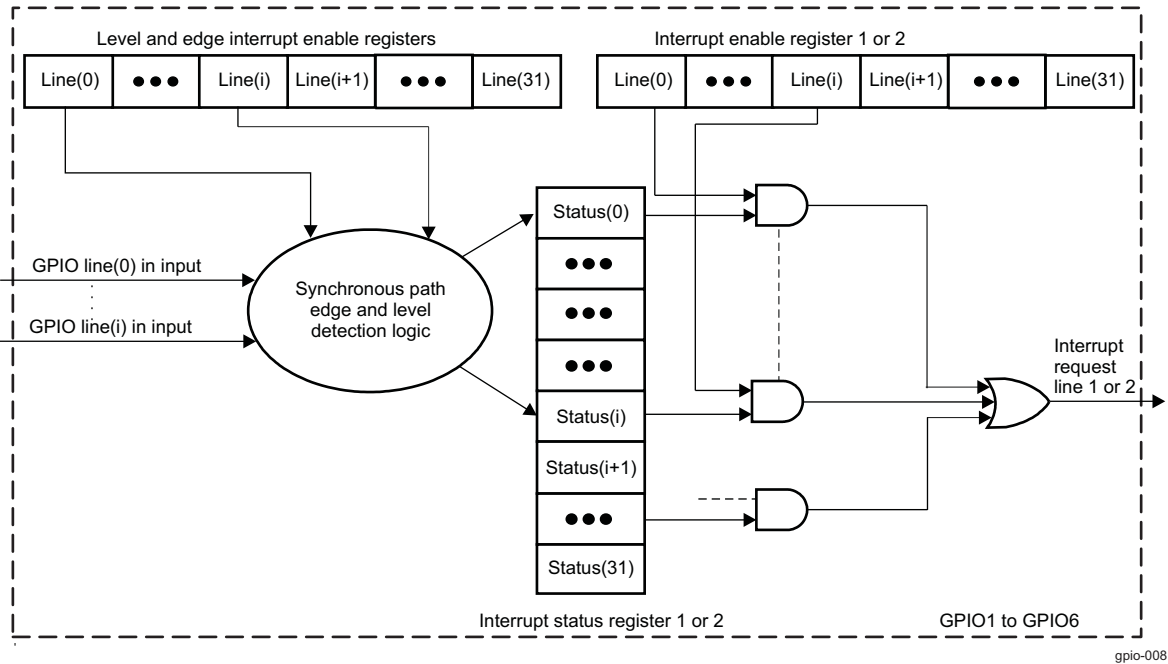

Because the module is synchronous, latency is minimal between the expected event occurrence and the activation of the interrupt line(s). This latency must not exceed four internally gated interface clock cycles + one interface clock cycle when the debounce feature is not used.

When the debounce feature is active, the latency depends on the value of the debouncing time register (GPIOi.GPIO_DEBOUNCINGTIME) (see [Section 25.4.3, General-Purpose Interface Clock Configuration](#)) and is less than three internally gated interface clock cycles plus two interface clock cycles plus GPIOi.GPIO_DEBOUNCINGTIME register value debounce clock cycles plus three debounce clock cycles.

Synchronous interrupt request line 1 is mapped on the Cortex-A9 MPU and Cortex-M3 MPU subsystems.
 Synchronous interrupt request line 2 is mapped on the DSP INTC.

Figure 25-10 is an overview of the interrupt request generation.

Figure 25-10. Interrupt Request Generation

25.4.2.2 Asynchronous Path: Wake-Up Request Generation

The general-purpose interface has six wake-up lines (one wake-up line per GPIO module instance) connected to the PRCM module.

Asynchronous wake-up requests from input channels are merged to issue one wake-up signal to the system per each GPIO module. The wake-up-enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) select the channel(s) considered for the wake-up request generation. The asynchronous wake-up request is reflected into the synchronous interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1).

In idle mode (the interface clock is shut down and the GPIO configuration registers are programmed; see Section 25.4.6, *General-Purpose Interface Interrupt and Wake-Up Requests*), an asynchronous path detects the expected transition(s) on a GPIO input (based on register programming) and activates an asynchronous wake-up request by the sideband signal (GPIOi_SWAKEUP, where i = 1, 2, 3, 4, 5, or 6), if the wake-up-enable register is set.

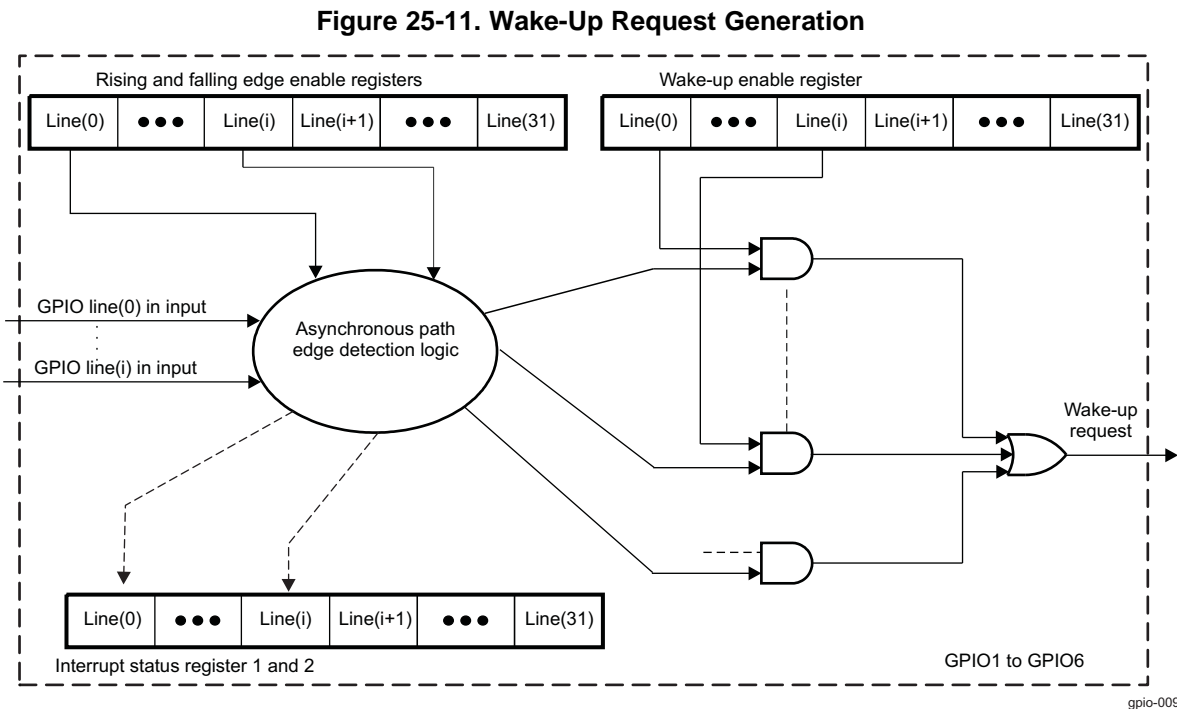

When the system is awakened, the interface clock is restarted and synchronously set to 1 based on the input GPIO pin triggering the wake-up request and the corresponding bit in the interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1). On the following internal clock cycle, interrupt lines 1 and/or 2 are active (active low) when the corresponding bits are set in the interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0 and GPIOi.GPIO_IRQSTATUS_CLR_1).

NOTE: When debouncing is not enabled, a minimum input pulse width does not trigger the wake-up request because there is no sampling operation.

When debouncing is enabled, the minimum pulse width is set by the specified debouncing time.

The GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit enables or disables the GPIO wake-up feature globally. If the bit is set to 0, the wake-up-enable registers (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) have no effect.

Figure 25-11 is an overview of the wake-up request generation.

25.4.2.3 Wake-Up Event Conditions During Transition To and From IDLE State

Figure 25-12 shows the wake-up event conditions.

In phase A, only the synchronous path is enabled. A synchronous interrupt request (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s) and prevents the GPIO from transitioning into IDLE state until the interrupt is cleared.

In phase B, the asynchronous path and synchronous path are enabled during the first five functional clock cycles of the SLEEPTRANS state. During this period a synchronous interrupt request (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) prevents the GPIO from transitioning into IDLE state. A shorter pulse puts the module into IDLE state but triggers a wakeup once in IDLE.

In phase C, only the asynchronous path is enabled. A wake-up request (see [Section 25.4.2.2, Asynchronous Path: Wake-Up Request Generation](#)) triggers a wake-up request from the GPIO and when the module is awakened an interrupt is generated. If debouncing is not enabled, there is no minimum input pulse width to trigger the wake-up request.

In phase D, eight OCP clock cycles occur until the module is in FUNCT state, the synchronous path is enabled, and an event that fulfills the pulse width requirements (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s).

In phase E, only the synchronous path is enabled. A synchronous interrupt request (see [Section 25.4.2.1, Synchronous Path: Interrupt Request Generation](#)) activates the interrupt line(s).

Figure 25-12. Wake-Up Event Conditions

gpio-014

25.4.2.4 Interrupt (or Wake-Up) Line Release

When the host processor (the MPU and/or DSP subsystem in the device) receives an interrupt request issued by the GPIO, it reads the corresponding interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) to determine which GPIO input triggered the interrupt (or the wake-up request).

After servicing the interrupt (or acknowledging the wake-up request), the software resets the status bit and releases the interrupt line by setting the corresponding bit of the interrupt status register to 1. If there is still a pending interrupt request to serve (all bits in the interrupt status register that are not masked by the interrupt-enable register are not cleared), the interrupt line is reasserted.

NOTE: The status bit must be reset to re-enter idle mode.

25.4.3 General-Purpose Interface Clock Configuration

25.4.3.1 Clocking

Each GPIO uses two clocks:

- **Debounce clock:** The 32-kHz debounce clock, GPIOi_DBCLK (where i = 1, 2, 3, 4, 5, or 6, with one debounce clock per module) comes from the PRCM module and is used for the debounce cell logic (without the corresponding configuration registers). This cell can sample the input line and filters the input level using a programmed delay.

The debouncing value register (GPIOi.GPIO_DEBOUNCINGTIME) is used to set the debouncing time for all input lines in the GPIO module. The value is global for all the ports of one GPIO, so up to six different debouncing values are possible. The debounce cell is running with the debounce clock (32 kHz). This register represents the number of clock cycle(s) to be used (one cycle is 31 μ s long).

The following formula describes the required input stable time to be propagated to the debounced output:

Required input line stable = (GPIOi.GPIO_DEBOUNCINGTIME[7:0] DEBOUNCVL bit field value + 1) \times 31,

where the value of the DEBOUNCVL bit field is from 0 to 255.

For more information, see [Section 3.6.8, CD_L4_PER_Clock Domain](#), and [Section 3.6.4, CD_WKUP_Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- **Interface clock:** The interface clock, GPIOi_ICLK (where i = 1, 2, 3, 4, 5, or 6), comes from the PRCM module and is used throughout the GPIO (except within the debounce cell logic). GPIOi_ICLK clocks the data exchanges between the L4 interconnect and the internal logic. The clock-gating features allow module power consumption to be adapted to the activity.

For more information, see [Section 3.6.8, CD_L4_PER_Clock Domain](#), and [Section 3.6.4, CD_WKUP_Clock Domain](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 25-3](#) describes the GPIO clocks.

[Table 25-5](#) summarizes the functional clock configuration.

Table 25-5. Functional Clock Configuration

| Interface Clock | GPIO_CTRL[2:1] GATINGRATIO | Functional Clock |
|------------------------------|----------------------------|---------------------------------|
| GPIOi_ICLK, where i = 1 to 6 | 00 | GPIOi_ICLK /1, where i = 1 to 6 |
| GPIOi_ICLK, where i = 1 to 6 | 01 | GPIOi_ICLK /2, where i = 1 to 6 |
| GPIOi_ICLK, where i = 1 to 6 | 10 | GPIOi_ICLK /4, where i = 1 to 6 |
| GPIOi_ICLK, where i = 1 to 6 | 11 | GPIOi_ICLK /8, where i = 1 to 6 |

25.4.4 General-Purpose Interface Hardware and Software Reset

The GPIO can be reset by using the domain reset (hardware reset) or by setting a dedicated configuration bit (software reset) in each GPIO.

- **Hardware reset:** GPIO2 to GPIO6 are attached to the PER_RST reset domain. GPIO1 is attached to the WKUP_RST reset domain.

The hardware reset has a global reset action on the GPIOs of the general-purpose interface. All configuration registers and internal logic are reset when it is active (low level). In each GPIO, the GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit monitors the internal reset status; it is set when the reset completes. For more information, see [Section 3.5.4, Reset Domains](#), in [Chapter 3, Power, Reset, and Clock Management](#).

- **Software reset:** Each GPIO has its own software reset using the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit (where i = 1, 2, 3, 4, 5, or 6). The software reset has the same effect as the hardware reset signal, but this reset can be applied on one or more modules.

Setting the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit to 1, (where i = 1, 2, 3, 4, 5, or 6) resets the module. A bit value of 1 remains until the reset completes. When the software reset completes, the GPIOi.GPIO_SYSCONFIG[1] SOFTRESET bit is automatically reset to 0 and has the same effect as a

hardware reset. The GPIOi.GPIO_SYSSTATUS[0] RESETDONE bit is cleared during a software reset. This bit is set to 1 when the software reset completes.

25.4.5 General-Purpose Interface Power Management

25.4.5.1 Power Domain

GPIO1 is attached to the WKUP power domain (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). This domain is composed of the logic permanently supplied to manage domain power state transitions and detect wake-up events. The WKUP power domain is continuously active. GPIO2 to GPIO6 are attached to the PER power domain (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)). The PER power domain is not active continuously.

25.4.5.2 Power Management

25.4.5.2.1 Idle Scheme

To reduce dynamic consumption, an efficient idle scheme is based on the following:

- An efficient local autoclock gating for each module
- The implementation of control sideband signals between the PRCM module and each module

This enhanced idle control allows clocks to be activated and deactivated safely without requiring complex software management.

The idle mode request, idle acknowledge, and wake-up request (GPIOi_WAKEUP, where $i = 1, 2, 3, 4, 5$, or 6) are sideband signals between the PRCM module and the general-purpose interface (see [Section 25.4.6.2, Wake-Up Request Generation](#)).

25.4.5.2.2 Operating Modes

The following four operating modes are defined for the modules:

- Active mode: The module runs synchronously on the interface clock; interrupts can be generated based on the configuration and external signals.
- Idle mode: Power-saving mode with the module in a waiting state. The interface clock can be stopped, an interrupt cannot be generated, and a wake-up signal can be generated based on the configuration and external signals.
If the debounce clock provided by the PRCM module is active, the debounce cell can sample and filter the input to generate a wake-up event. If the debounce clock is inactive, the debounce cell gates all input signals and thus cannot be used.
- Inactive mode: The module has no activity. The interface clock can be stopped, an interrupt cannot be generated, and the wake-up feature is inhibited.
- Disabled mode: The module is not used. The internal clock paths are gated, and an interrupt or wake-up request cannot be generated.

Idle and inactive modes are configured within the module and activated on request by the PRCM module (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)) through sideband signals (see [Section 25.4.5.2.3, System Power Management and Wakeup](#)).

The disabled mode is set by software through a dedicated configuration bit, GPIOi.GPIO_CTRL[0] DISABLEMODULE (0: The module is enabled and clocks are not gated; 1: The module is disabled and clocks are gated). It unconditionally gates the internal clock paths that are not used for the L4 interconnect.

25.4.5.2.3 System Power Management and Wakeup

The PRCM module can require the GPIOs to be idled for power-saving purposes.

The general-purpose interface has six identical idle mode request/acknowledge (handshake) mechanisms with the PRCM module (see [Section 25.4.6.2, Wake-Up Request Generation](#)): one per GPIO. The general-purpose interface allows the GPIOs to enter idle mode based on the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field.

Idle acknowledge depends on the configuration and activity of each GPIO:

- Smart-idle mode

When the GPIO is configured in smart-idle mode, it checks for more activity (capture of the input GPIO pins in the GPIOi.GPIO_DATAIN register is complete with no pending interrupt; all interrupt status bits are cleared), and there is no access to the GPIO.GPIO_DEBOUNCINGTIME register, which is waiting to be synchronized.

Idle acknowledge is then asserted and the module enters into idle-mode. It waits for active system clock gating by the PRCM module (when all peripherals supplied by the same L4 interface clock domain are also ready for idle).

In idle mode (that is, when the PRCM module gates the interface clock), no interrupt occurs.

- Smart-idle wake-up mode

If the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field selects smart-idle or smart-idle wake-up mode, the GPIO module evaluates its internal capability to switch off the interface clock. Once all internal activity ceases (the DATA INPUT REGISTER completed to capture the input GPIO pins, there is no pending interrupt, all interrupt status bits are cleared, and there is no write access to the GPIO_DEBOUNCINGTIME register pending to be synchronized), the Idle acknowledge is asserted and the GPIO enters into idle mode, ready to issue a wake-up request when the expected transition occurs on an enabled GPIO input pin. This wake-up request is effectively sent only if the GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit of the system configuration register enables the GPIO wake-up capability (see [Section 25.6.2.2, System Configuration Register](#)). When the system is awake, the idle request goes inactive, the idle acknowledge and wake-up request (if the GPIO triggered the systems wakeup) signals are immediately deasserted, and the asynchronous wake-up request (if existing) is reflected into the synchronous interrupt status registers.

- Force-idle mode

When the GPIO is configured in force-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 2b00) and receives an idle request from the PRCM module, the GPIO waits unconditionally for active system clock gating by the PRCM module. (This occurs only when all peripherals supplied by the same L4 interface clock domain are also ready for idle.)

When in idle mode (that is, when the PRCM module gates the interface clock), the module (in inactive mode) has no activity, the interface clock paths are gated, an interrupt cannot be generated, and the wake-up feature is totally inhibited.

- No-idle mode

When the GPIO is configured in no-idle mode (the GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field = 2b01) and receives an idle request from the PRCM module, the GPIO does not go into idle mode and the idle acknowledge is never sent.

NOTE: For more information about idle modes, see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

25.4.5.2.4 Module Power Saving

The GPIO has local power management by internal clock-gating features:

- Internal interface clock gating: The clock for the L4 interconnect logic can be gated when the GPIO is not accessed, if the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit is set. Otherwise, this logic is free-running on the interface clock.
- Clock gating for the input data sample logic: Clock for the input data sample logic can be gated when the data in the GPIOi.GPIO_DATAIN register is not accessed.
- Clock gating for the event detection logic: Each GPIO implements four clock groups used for the logic in the synchronous event detection. Each group of eight input GPIO pins has a separate enable signal depending on the setting of the edge/level detection register (because the input is 32 bits, four groups

of eight inputs are defined for each GPIO). If a group requires no detection, the corresponding clock is gated.

Grouping the edge/level enable can save the power consumption of the module.

If any of the following registers is set to 0x01 01 01 01, then all clocks are active (power consumption is high). If they are set to 0x00 00 00 FF, then a single clock is active (power saving).

- GPIOi.GPIO_LEVELDETECT0
- GPIOi.GPIO_LEVELDETECT1
- GPIOi.GPIO_RISINGDETECT
- GPIOi.GPIO_FALLINGDETECT

NOTE: When the clocks are enabled by writing to the following registers, the detection starts after five clock cycles. This period is required to clean the synchronization edge/level detection pipeline.

- GPIOi.GPIO_LEVELDETECT0
- GPIOi.GPIO_LEVELDETECT1
- GPIOi.GPIO_RISINGDETECT
- GPIOi.GPIO_FALLINGDETECT

The mechanism is independent of each clock group. If the clock has been started before and a new setting is performed, the following is recommended:

1. Set the new detection required.
2. Disable the previous setting (if necessary).

In this way, the corresponding clock is not gated and the detection starts immediately.

All channels are also gated using a one-out-of-N scheme. N is the GPIOi.GPIO_CTRL[2:1] GATINGRATIO bit field and can take the values 1 (2b00), 2 (2b01), 4 (2b10), or 8 (2b11). The interface clock is enabled for this logic one cycle every N cycles. When N is equal to 1, there is no gating and this logic is free-running on the interface clock. When N is 2, 4, or 8, this logic is running at the equivalent frequency of interface clock frequency divided by N.

- Inactive mode: In inactive mode, all internal clock paths are gated.
- Disabled mode: All internal clock paths not used for the L4 interconnect are gated. The GPIOi.GPIO_CTRL[0] DISABLEMODULE bit controls a clock-gating feature at the module level. When set to 1, this bit forces clock gating for all internal clock paths. Internal activity in the module is suspended. The L4 interconnect is not affected by this bit.

The interface clock gating is controlled through the GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit, which is used to save power when the module is not used because of the multiplexing configuration selected at the device level. This bit takes precedence over all other internal configuration bits.

Table 25-6 describes the power-management features available for the general-purpose interface module.

NOTE: For information about source clock gating and a description of sleep/wake-up transitions, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

For descriptions of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 25-6. Local Power-Management Features

| Feature | Registers | Description |
|------------------|----------------------------------------------|--------------------------------------------------------------------------|
| Clock autogating | GPIOi.GPIO_SYSCONFIG[0] AUTOIDLE bit | Sets the clock gating strategy for the OCP interface block. |
| Slave idle modes | GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE bit field | Force-idle, no-idle, and smart-idle wake-up-capable modes are available. |

Table 25-6. Local Power-Management Features (continued)

| Feature | Registers | Description |
|------------------------|------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| Clock activity | GPIOi.GPIO_CTRL[0] DISABLEMODULE bit field | Enable and disable the module. |
| Debouncing enable | GPIOi.GPIO_DEBOUNCENABLE[31:0] DEBOUNCEENABLE bit field | Debouncing mode is available. |
| Global wake-up enable | GPIOi.GPIO_SYSCONFIG[2] ENAWAKEUP bit | This bit enables the wake-up feature at module level. |
| Wake-up sources enable | GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE bit field GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE bit field | This register enables or disables a specific IRQ request source to generate a wake-up signal. |

Table 25-7 describes the clock activity settings.

Table 25-7. Clock Activity Settings

| GPIOi.GPIO_SYSCONFIG[4:3] IDLEMODE | Selected Mode | Description | Wake-Up Events |
|------------------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------|
| 00 | Force-idle | The GPIO goes into inactive mode independently of the internal module state, and the Idle acknowledge is never sent. | No |
| 01 | No-idle | The GPIO does not go into the idle mode and the idle acknowledge is never sent. | No |
| 10 | Smart-idle | The GPIO evaluates its internal capability to switch off the interface clock. If there is no more internal activity, the idle acknowledge is asserted and the GPIO enters into idle mode. | No |
| 11 | Smart-idle wake-up | The GPIO evaluates its internal capability to have the interface clock switched off. If there is no more internal activity, the idle acknowledge is asserted and the GPIO enters into idle mode. | Yes |

25.4.6 General-Purpose Interface Interrupt and Wake-Up Requests

25.4.6.1 Interrupt Request Generation

All interrupt sources (the 32 GPIO input channels) are merged to issue two synchronous interrupt requests in each GPIO module. Thus, the general-purpose interface has 12 interrupt lines (two interrupt lines per each GPIO instance).

- Synchronous interrupt request line 1 is mapped on the Cortex-A9 and Cortex-M3 MPU INTCs.
- Synchronous interrupt request line 2 is mapped on the DSP INTC.

Table 25-8 lists the event flags, and their mask, that can cause module interrupts.

Table 25-8. Events

| Event Flag | Event Mask | Synchronous | Sensitivity | Map to | Description |
|---------------------------------------|------------------------------------------|-------------|-------------|-------------------------------------|---------------------------------------------|
| GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE | GPIOi.GPIO_IRQSTATUS_SET_0[31:0] INTLINE | Yes | Edge/level | MA_IRQ_n MM_IRQ_n ⁽¹⁾ | Corresponds to the first line of interrupt |
| GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE | GPIOi.GPIO_IRQSTATUS_SET_1[31:0] INTLINE | Yes | Edge/level | D_IRQ_n | Corresponds to the second line of interrupt |
| GPIOi.GPIO_IRQSTATUS_0 [31:0] INTLINE | GPIOi.GPIO_IRQSTATUS_CLR_0[31:0] INTLINE | Yes | Edge/level | MA_IRQ_n MM_IRQ_n ⁽¹⁾ | Corresponds to the first line of interrupt |
| GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE | GPIOi.GPIO_IRQSTATUS_CLR_1[31:0] INTLINE | Yes | Edge/level | D_IRQ_n | Corresponds to the second line of interrupt |
| GPIOi.GPIO_IRQSTATUS_0[31:0] INTLINE | GPIOi.GPIO_IRQWAKEN_0[31:0] INTLINE | No | Edge/level | MA_IRQ_n MM_IRQ_n ⁽¹⁾ | Corresponds to the first line of interrupt |
| GPIOi.GPIO_IRQSTATUS_1[31:0] INTLINE | GPIOi.GPIO_IRQWAKEN_1[31:0] INTLINE | No | Edge/level | D_IRQ_n | Corresponds to the second line of interrupt |

⁽¹⁾ For GPIO1 and GPIO2 only

Synchronous interrupt request lines 1 and 2 are active depending on their respective interrupt enable 1 and 2 registers (GPIOi.GPIO_IRQSTATUS_SET_0, GPIOi.GPIO_IRQSTATUS_SET_1, GPIOi.GPIO_IRQSTATUS_CLR_0 and GPIOi.GPIO_IRQSTATUS_CLR_1).

- Interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1)

The interrupt-enable1 (or interrupt-enable2) register allows masking of the expected transition on input GPIO to prevent the generation of an interrupt request on line1 (or line2). The interrupt-enable registers are programmed synchronously with the interface clock.

These registers can be accessed with direct read/write operations or using the alternate set-and-clear protocol feature for register update. This feature allows the setting or clearing of explicit bits of these registers with a single write access (see [Section 25.4.9, General-Purpose Interface Set-and-Clear Protocol](#)).

- Interrupt status registers (GPIOi.GPIO_IRQSTATUS_0 and GPIOi.GPIO_IRQSTATUS_1)

The interrupt status1 (or interrupt status2) register determines which of the input GPIO pins triggered the interrupt line1 (or interrupt line2) request (or the wake-up line).

When a bit in this register is set to 1, it indicates that the corresponding GPIO pin is requesting the interrupt (or the wakeup). To reset a bit in this register, write 1 to the appropriate bit. However, an interrupt cannot be generated by writing 1 to the interrupt status1 (or interrupt status2) register.

If 0 is written to a bit in this register, the value remains unchanged. The interrupt status1 (or interrupt status2) register is synchronous with the interface clock. In idle mode, the event is detected through an asynchronous path, and the corresponding bit in the interrupt status1 and interrupt status2 registers are set when the GPIO is awakened.

CAUTION

After servicing the interrupt, the status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset and the interrupt line released (by setting the corresponding bit of the interrupt status register to 1).

Before enabling an interrupt for the GPIO channel in the interrupt-enable register (GPIOi.GPIO_IRQSTATUS_SET_0 or GPIOi.GPIO_IRQSTATUS_SET_1), the corresponding status bit in the interrupt status register (GPIOi.GPIO_IRQSTATUS_0 or GPIOi.GPIO_IRQSTATUS_1) must be reset to prevent the occurrence of unexpected interrupts when enabling an interrupt for the GPIO channel.

25.4.6.2 Wake-Up Request Generation

GPIO1 of the general-purpose interface is attached to the WKUP power domain (see [Section 3.1.1.2, Power Management](#), in [Chapter 3, Power, Reset, and Clock Management](#)) and can wake up the system.

NOTE: GPIO2 to GPIO6 belong to the PER power domain and thus their wake-up capabilities are operational only when the PER power domain is active.

All wake-up sources (the 32 input GPIO channels) are merged together to issue a single asynchronous wake-up request in each GPIO following the expected transition(s) (based on register programming). Each GPIO generates a wake-up signal to the PRCM module.

NOTE: Only gpio_wk[10:0] and gpio_wk[31:29] can be used to generate a direct wake-up event.

The asynchronous wake-up request line is active based on the GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1 wake-up-enable registers (where i = 1, 2, 3, 4, 5, or 6).

The wake-up-enable register allows masking of the expected transition on input GPIO to prevent the generation of a wake-up request. The wake-up-enable register is programmed synchronously with the interface clock before any idle mode request coming from the host processor.

NOTE: There must be a correlation between the wake-up enable and interrupt-enable registers. If a GPIO pin has a wake-up configured on it, it must also have the corresponding interrupt enabled (on one of the two interrupt lines). Otherwise, it is possible to have a wake-up event, but after exiting the IDLE state, no interrupt is generated; thus, the corresponding bit from the interrupt status register is not cleared, and the module does not acknowledge a future idle request.

Table 25-9 lists the mapping of the wake-up signals.

Table 25-9. Wake-Up Signals

| Name | Mapping | Comments |
|------------|---------------|----------------------------------------------------------------|
| GPIOi_WAKE | GPIOi_SWAKEUP | Where i = 1, 2, 3, 4, 5, and 6. Destination is the PRM module. |

25.4.7 General-Purpose Interface Channel Description

Table 25-10 describes the GPIO channels.

Table 25-10. GPIO Channel Description

| Channel Number | Type ⁽¹⁾ | Mapping | Wake-Up Feature | Comments |
|---------------------|---------------------|---------------|--------------------|----------------------------------------------|
| GPIO1 | | | | |
| [31] | I/O | gpio_wk31 | Yes | Wake-up path |
| [30] | I/O | gpio_wk30 | Yes | Wake-up path |

| GPIO6 | | | | |
| [31:21] | I/O | gpio_[191:181] | Yes ⁽²⁾ | GPIO |
| [20] ⁽³⁾ | I | DPDM5VSHORT | Yes ⁽²⁾ | USB OTG PHY short detect (DPDM5VSHORT) |
| [19] ⁽³⁾ | I | CHGDETECT | Yes ⁽²⁾ | USB OTG PHY charge detect (CHGDETECT) |
| [18:15] | I/O | gpio_[178:175] | Yes ⁽²⁾ | GPIO |
| [14:0] | I/O | gpio_[174:160] | Yes ⁽²⁾ | GPIO |

NOTE: The thermal shutdown comparator output signal (TSHUT) is an output from the BANDGAP module. This signal is high during normal operation and goes low during a thermal shutdown event. When channel 22 of the GPIO3 is not connected to a ball of the device (the corresponding pin is configured in a mode different from configuration mode 4; see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), in [Chapter 18, Control Module](#), for more information about pin configuration), TSHUT is connected to channel 22 of GPIO3. The channel must be configured correctly so that it can generate an interrupt when a high-to-low transition occurs on TSHUT.

NOTE: Channels 20 and 19 of GPIO6 are internally connected inside the device to the short detection (DPDM5VSHORT) and charger detection (CHGDETECT) outputs, respectively, of the USB OTG PHY module. This allows interrupt generation on the corresponding GPIO channel, if either of the mentioned events occurs.

25.4.8 General-Purpose Interface Data Input/Output Capabilities

The output-enable register (GPIOi.GPIO_OE) controls the output/input capability of each pin. At reset, all the GPIO-related pins are configured as inputs, and their output capabilities are disabled. This register is not used within the module. Its only function is to carry the pad configuration.

When configured as an output (the desired bit reset in the GPIOi.GPIO_OE register), the value of the corresponding bit in the GPIOi.GPIO_DATAOUT register is driven on the corresponding GPIO pin. Data is written to the data-output register synchronously with the interface clock. This register can be accessed with read/write operations or by using the alternate set-and-clear protocol register update feature. This feature gives the possibility to set or clear specific bits of this register with a single write access to the set-output data register (GPIOi.GPIO_SETDATAOUT) or to the clear-output data register (GPIOi.GPIO_CLEARDATAOUT) address (see [Section 25.4.9, General-Purpose Interface Set-and-Clear Protocol](#)). If the application uses a pin as an output and does not want interrupt/wake-up generation from this pin, the application must properly configure the wake-up-enable (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1) registers.

When configured as an input (the desired bit is set to 1 in the GPIOi.GPIO_OE register), the state of the input can be read from the corresponding bit in the GPIOi.GPIO_DATAIN register. The input data is sampled synchronously with the interface clock and then captured in the data input register synchronously with the interface clock. When the GPIO pin levels change, they are captured into this register after two interface clock cycles (the required cycles to synchronize and to write data). If the application uses a pin

as an input, the application must properly configure the wake-up enable (GPIOi.GPIO_IRQWAKEN_0 and GPIOi.GPIO_IRQWAKEN_1) and the interrupt-enable (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_0) registers to the interrupt and wake-up feature as needed. For using the alternate set-and-clear protocol, see [Section 25.4.9, General-Purpose Interface Set-and-Clear Protocol](#).

25.4.9 General-Purpose Interface Set-and-Clear Protocol

25.4.9.1 Description

The GPIO module implements the set-and-clear protocol register update for the following registers:

- GPIOi.GPIO_DATAOUT
- GPIOi.GPIO_IRQSTATUS_CLR_0
- GPIOi.GPIO_IRQSTATUS_CLR_1
- GPIOi.GPIO_IRQSTATUS_SET_0
- GPIOi.GPIO_IRQSTATUS_SET_1

This protocol is an alternative to the atomic test and set operations and consists of writing operations at dedicated addresses (one address for setting bit[s] and one address for clearing bit[s]). The data to write is 1 at bit position(s) to clear (or to set) and 0 at unaffected bit(s). Registers can be accessed in two ways:

- Standard: Full register read and write operations at the primary register address
- Set and clear: Separate addresses are provided to set (and clear) bits in registers. Writing 1 at these addresses sets (or clears) the corresponding bit into the equivalent register; writing 0 has no effect.

Therefore, for these registers, three addresses are defined for one unique physical register. Reading these addresses has the same effect and returns the register value.

25.4.9.2 Clear Instruction

25.4.9.2.1 Clear Register Addresses

- Clear interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_CLR_0 and GPIOi.GPIO_IRQSTATUS_CLR_1).
A write operation in the GPIO_IRQSTATUS_CLR_0 (or GPIO_IRQSTATUS_CLR_1) register clears the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.
A read of the clear interrupt-enable0 (or enable1) register returns the value of the GPIO_IRQSTATUS_CLR_0 (or GPIO_IRQSTATUS_CLR_1) register.
- Clear data-output register (GPIOi.GPIO_CLEARDATAOUT).
A write operation in the clear data-output register clears the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.
A read of the clear data-output register returns the value of the data-output register.

25.4.9.2.2 Clear Instruction Example

Assume the data-output register (or one of the interrupt/wake-up-enable register) contains the binary value, 0b0000 0001 0000 0001, and bit 0 is to be clear.

With the clear instruction feature, write 0b0000 0000 0000 0001 at the address of the clear data-output register (or at the address of the clear interrupt/wake-up-enable register). After this write operation, a reading of the data-output register (or the interrupt/wake-up-enable register) returns 0b0000 0001 0000 0000; bit 0 is cleared.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the least-significant 16 bits are represented in this example.

Figure 25-13 shows an example of a clear instruction.

Figure 25-13. GPIO_CLEARDATAOUT Register Example

25.4.9.3 Set Instruction

25.4.9.3.1 Set Register Addresses

- Set interrupt-enable registers (GPIOi.GPIO_IRQSTATUS_SET_0 and GPIOi.GPIO_IRQSTATUS_SET_1).
A write operation in the GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register sets the corresponding bit in the same register when the written bit is 1; a written bit at 0 has no effect.
A read of the set interrupt-enable0 (or enable1) register returns the value of the interrupt GPIOi.GPIO_IRQSTATUS_SET_0 (or GPIOi.GPIO_IRQSTATUS_SET_1) register.
- Set data-output register (GPIOi.GPIO_SETDATAOUT).
A write operation in the set data-output register sets the corresponding bit in the data-output register when the written bit is 1; a written bit at 0 has no effect.
A read of the set data-output register returns the value of the data-output register.

25.4.9.3.2 Set Instruction Example

Assume the interrupt-enable1 (or enable2) register (or the data-output register) contains the binary value, 0b0000 0001 0000 0000, and bits 15, 3, 2, and 1 are to be set.

With the set instruction feature, write 0b1000 0000 0000 1110 at the address of the set interrupt enable1 (or enable2) register (or at the address of the set data-output register). After this write operation, a reading of the interrupt-enable1 (or enable2) register (or the data-output register) returns 0b1000 0001 0000 1110; bits 15, 3, 2, and 1 are set.

NOTE: Although the general-purpose interface registers are 32 bits wide, only the least-significant 16 bits are represented in this example.

Figure 25-14 shows an example of a set instruction.

Figure 25-14. Write in GPIO_IRQSTATUS_SET_0 Register Example

The set wake-up-enable register offers the same feature with the wake-up-enable register.

25.5 General-Purpose Interface Programming Guide

25.5.1 General-Purpose Interface Low-Level Programming Models

25.5.1.1 Global Initialization

25.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the general-purpose interface module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the general-purpose interface. For more information, see [Section 25.3, General-Purpose Interface Integration](#), and [Section 25.2, General-Purpose Interface Environment](#).

Table 25-11. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRCM | Module interface and functional clocks must be enabled. For more information about the module configuration, see Chapter 3, Power, Reset, and Clock Management . |
| Control module | Module-specific pad muxing must be set in the control module. For more information about the module configuration, see Chapter 18, Control Module . |
| MPU INTC | MPU INTC configuration must be done to enable the interrupts from the general-purpose interface module. See Chapter 17, Interrupt Controllers . |
| DSP INTC | DSP INTC configuration must be done to enable the interrupts from the general-purpose interface module. See Chapter 17, Interrupt Controllers . |

25.5.1.1.2 General-Purpose Interface Module Global Initialization

This procedure initializes the general-purpose interface module after a POR or software reset.

Table 25-12. General-Purpose Interface Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| Execute software reset. | GPIO_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset completed? | GPIO_SYSSTATUS[0] RESETDONE | = 0x1 |
| Configure idle mode. | GPIO_SYSCONFIG[4:3] IDLEMODE | 0x– |
| Configure interface clock gating. | GPIO_SYSCONFIG[0] AUTOIDLE | 0x– |
| Set clock gating power saving. | GPIO_LEVELDETECT0[31:0] LEVELDETECT0 and GPIO_LEVELDETECT1[31:0] LEVELDETECT1 and GPIO_RISINGDETECT[31:0] RISINGDETECT and GPIO_FALLINGDETECT[31:0] FALLINGDETECT | 0x0000 00FF |
| Set clock gating ratio. | GPIO_CTRL[2:1] GATINGRATIO | 0x– |
| Configure GPIO channels as input or output. | GPIO_OE[31:0] OUTPUTEN | 0x– |
| Set debounce time value. | GPIO_DEBOUNCINGTIME[7:0] DEBOUNCETIME | 0x– |
| Enable/disable debouncing for desired input line. | GPIO_DEBOUNCENABLE[7:0] DEBOUNCENABLE | 0x– |
| Interrupt and Wake-Up Request Configuration | | |
| Enable/disable interrupts. | GPIO_IRQSTATUS_SET_0[31:0] INTLINE and/or GPIO_IRQSTATUS_SET_1[31:0] INTLINE | 0x– |
| Enable/disable wakeup for GPIO channels. | GPIO_IRQWAKEN_0[31:0] INTLINE and/or GPIO_IRQWAKEN_1[31:0] INTLINE | 0x– |
| Enable/disable wake-up generation. | GPIO_SYSCONFIG[2] ENAWAKEUP | 0x1 |

25.5.1.2 General-Purpose Interface Operational Modes Configuration

25.5.1.2.1 General-Purpose Interface Read Input Register

Table 25-13. General-Purpose Interface Read Input Register

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------|-------------------------------------------|-------|
| Read input register value. | GPIO_DATAIN [31:0] DATAIN | 0x- |

25.5.1.2.2 General-Purpose Interface Write Output Register

Table 25-14. General-Purpose Interface Write Output Register

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------------|---------------------------------------------|-------|
| Write value to output register. | GPIO_DATAOUT [31:0] DATAOUT | 0x- |

25.5.1.2.3 General-Purpose Interface Set Bit Function

Table 25-15. General-Purpose Interface Set Bit Function

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------------|-----------------------------------------------------|-------|
| Write 0x1 to set desired bit(s) in register. | GPIO_SETDATAOUT [31:0] INTLINE | 0x- |
| | GPIO_IRQSTATUS_SET_0 [31:0] INTLINE | |
| | GPIO_IRQSTATUS_SET_1 [31:0] INTLINE | |

25.5.1.2.4 General-Purpose Interface Clear Bit Function

Table 25-16. General-Purpose Interface Clear Bit Function

| Step | Register/Bit Field /Programming Model | Value |
|------------------------------------------------|-----------------------------------------------------|-------|
| Write 0x1 to clear desired bit(s) in register. | GPIO_CLEARDATAOUT [31:0] INTLINE | 0x1 |
| | GPIO_IRQSTATUS_CLR_0 [31:0] INTLINE | |
| | GPIO_IRQSTATUS_CLR_1 [31:0] INTLINE | |

25.6 General-Purpose Interface Register Manual

25.6.1 General-Purpose Interface Instance Summary

Table 25-17 summarizes the general-purpose interface instance.

Table 25-17. Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|------|
| GPIO1 | 0x4A31 0000 | 4KB |
| GPIO2 | 0x4805 5000 | 4KB |
| GPIO3 | 0x4805 7000 | 4KB |
| GPIO4 | 0x4805 9000 | 4KB |
| GPIO5 | 0x4805 B000 | 4KB |
| GPIO6 | 0x4805 D000 | 4KB |

25.6.2 General-Purpose Interface Registers

25.6.2.1 General-Purpose Interface Register Summary

Table 25-18 summarizes the general-purpose interface GPIO1 to GPIO3 registers.

Table 25-18. General-Purpose Interface GPIO1 to GPIO3 Registers Summary

| Bits | Field Name | Description | Type | Reset |
|------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|------------|
| 31:5 | RESERVED | Reserved | R | 0x00000000 |
| 4:3 | IDLEMODE | 0x0: Force-idle: An idle request is acknowledged unconditionally. 0x1: No-idle: An idle request is never acknowledged. 0x2: Smart-idle: The acknowledgment to an idle request is given based on the internal activity (see 4.1.2). 0x3: Smart-idle wakeup | RW | 0x0 |
| 2 | ENAWAKEUP | Wake-up control 0x0: Wake-up generation is disabled. 0x1: Wake-up capability is enabled upon expected transition on input GPIO pin. | RW | 0 |
| 1 | SOFTRESET | Software reset. Set this bit to 1 to trigger a module reset. The bit is automatically reset by the hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset. | RW | 0 |
| 0 | AUTOIDLE | OCP clock gating control. 0x0: Internal Interface OCP clock is free-running. 0x1: Automatic internal OCP clock gating, based on the OCP interface activity | RW | 0 |

Keyboard Controller

This chapter describes the keyboard module of the device.

| Topic | Page |
|-------------------------------------------------------|------|
| 26.1 Keyboard Controller Overview | 5569 |
| 26.2 Keyboard Controller Environment | 5571 |
| 26.3 Keyboard Controller Integration | 5574 |
| 26.4 Keyboard Controller Functional Description | 5576 |
| 26.5 Keyboard Controller Programming Guide | 5586 |
| 26.6 Keyboard Controller Register Manual | 5590 |

26.1 Keyboard Controller Overview

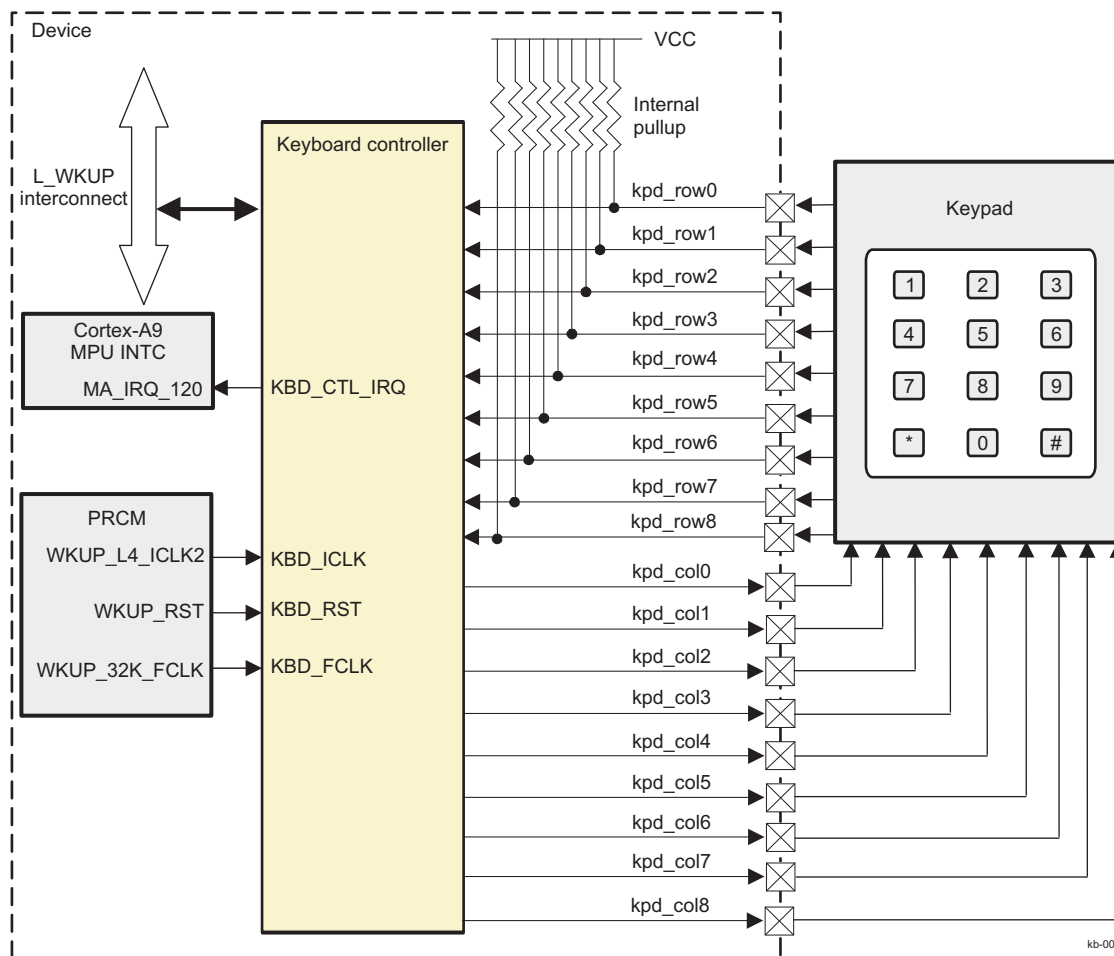

The keyboard controller implements a built-in scanning algorithm for hardware-based key-press decoding and reduces overhead in the microprocessor unit (MPU) software.

The keyboard controller includes a debouncing feature to ensure that only one key combination can be registered in the programmed time.

The keyboard controller can handle up to 9 × 9 keys, works on a 32-kHz clock, and can generate wake-up events when the chip is in sleep mode.

Figure 26-1 shows the keyboard controller.

Figure 26-1. Keyboard Controller Overview

The keyboard controller includes the following main features:

- Support of multiconfiguration keyboards up to 9 rows × 9 columns
- Each key coded on 1 bit in two 32-bit registers
- Long-key value or repeat timing reconfigurable on the fly
- Event detection on key press and key release
- Multikey-press detection and decoding
- Long-key detection on prolonged key press
- Integrated timer with four programmable comparison values
- Programmable time-out on permanent key press or after keyboard release
- Programmable interrupt generation on key events
- Software reset capability

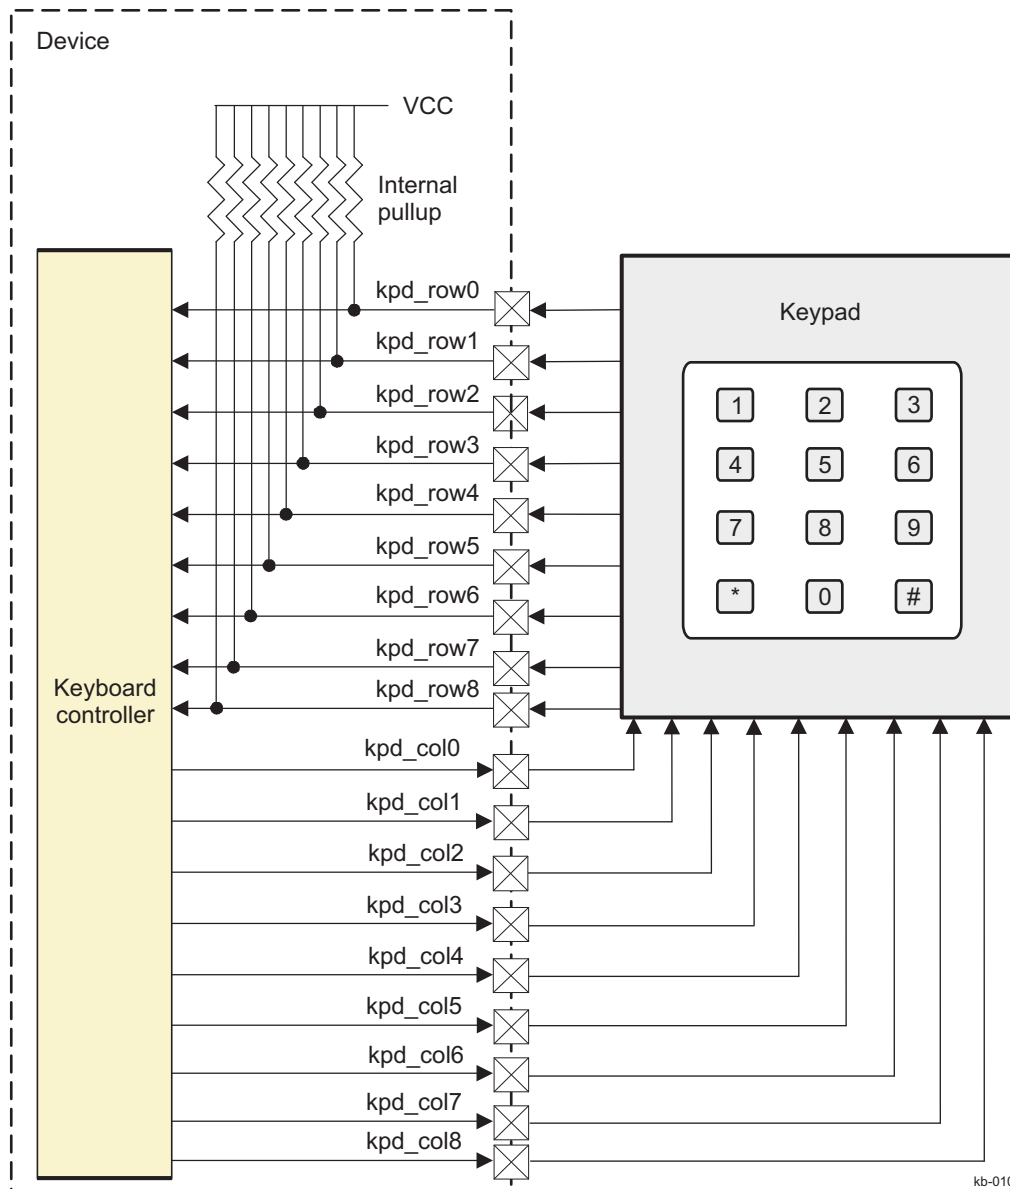

- Read/write-posted register access modes
- 8-/16-/32-bit access supported on the level 4 (L4) interface
- 32-bit data bus
- 7-bit address bus

26.2 Keyboard Controller Environment

The keyboard controller external interface pins map on the device pads when the device general-purpose input/output (GPIO) cells are configured and multiplexed for the keypad function by the control module. For more information, see [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), and [Section 25.2.1, General-Purpose Interface as a Keyboard interface](#).

The external keypad typically connects directly to the keyboard controller of the device (see [Figure 26-2](#)).

Figure 26-2. Typical Keyboard Environment

26.2.1 Keyboard Controller Functions/Modes

The keyboard controller executes two functions:

- Keypad scanning and decoding for input of the external key presses. For more information, see [Section 26.4.5, Keyboard Controller Software Mode](#), and [Section 26.4.6, Keyboard Controller Hardware Decoding Modes](#).
- Device wake-up by interrupt request to the processor when a key is pressed and the device is in idle or sleep mode. For more information, see [Section 26.4.6.4, Keyboard Controller Interrupt Generation](#).

26.2.2 Keyboard Controller Signals

Table 26-1 describes the module signals and specifies their links to functions.

Table 26-1. I/O External Keyboard Signals

| Signal | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ | Function | Wake-Up Capability |
|----------|--------------------|----------------------------------|----------------------------|-------------|--------------------|
| kpd_row0 | I | Keypad row 0 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row1 | I | Keypad row 1 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row2 | I | Keypad row 2 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row3 | I | Keypad row 3 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row4 | I | Keypad row 4 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row5 | I | Keypad row 5 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row6 | I | Keypad row 6 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row7 | I | Keypad row 7 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_row8 | I | Keypad row 8 feed | hi-Z (pulled up) | Key reading | Yes |
| kpd_col0 | O | Keypad column 0 feed, active low | hi-Z | Key reading | No |
| kpd_col1 | O | Keypad column 1 feed, active low | hi-Z | Key reading | No |
| kpd_col2 | O | Keypad column 2 feed, active low | hi-Z | Key reading | No |
| kpd_col3 | O | Keypad column 3 feed, active low | hi-Z | Key reading | No |
| kpd_col4 | O | Keypad column 4 feed, active low | hi-Z | Key reading | No |
| kpd_col5 | O | Keypad column 5 feed, active low | hi-Z | Key reading | No |
| kpd_col6 | O | Keypad column 6 feed, active low | hi-Z | Key reading | No |
| kpd_col7 | O | Keypad column 7 feed, active low | hi-Z | Key reading | No |
| kpd_col8 | O | Keypad column 8 feed, active low | hi-Z | Key reading | No |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

⁽²⁾ hi-Z = High impedance

26.2.3 Protocols and Data Formats

The keyboard controller detects and decodes multikey combinations using the following rules:

- Any 2-key combination is valid and can be decoded.
- Combinations using more than two keys are valid only if the rows and columns used do not cross over on another key to be detected. This is caused by equipotent propagation on a row/column (multikey limitations).

Figure 26-3 shows an example of multikey limitation.

Figure 26-3. Multikey Limitation Example

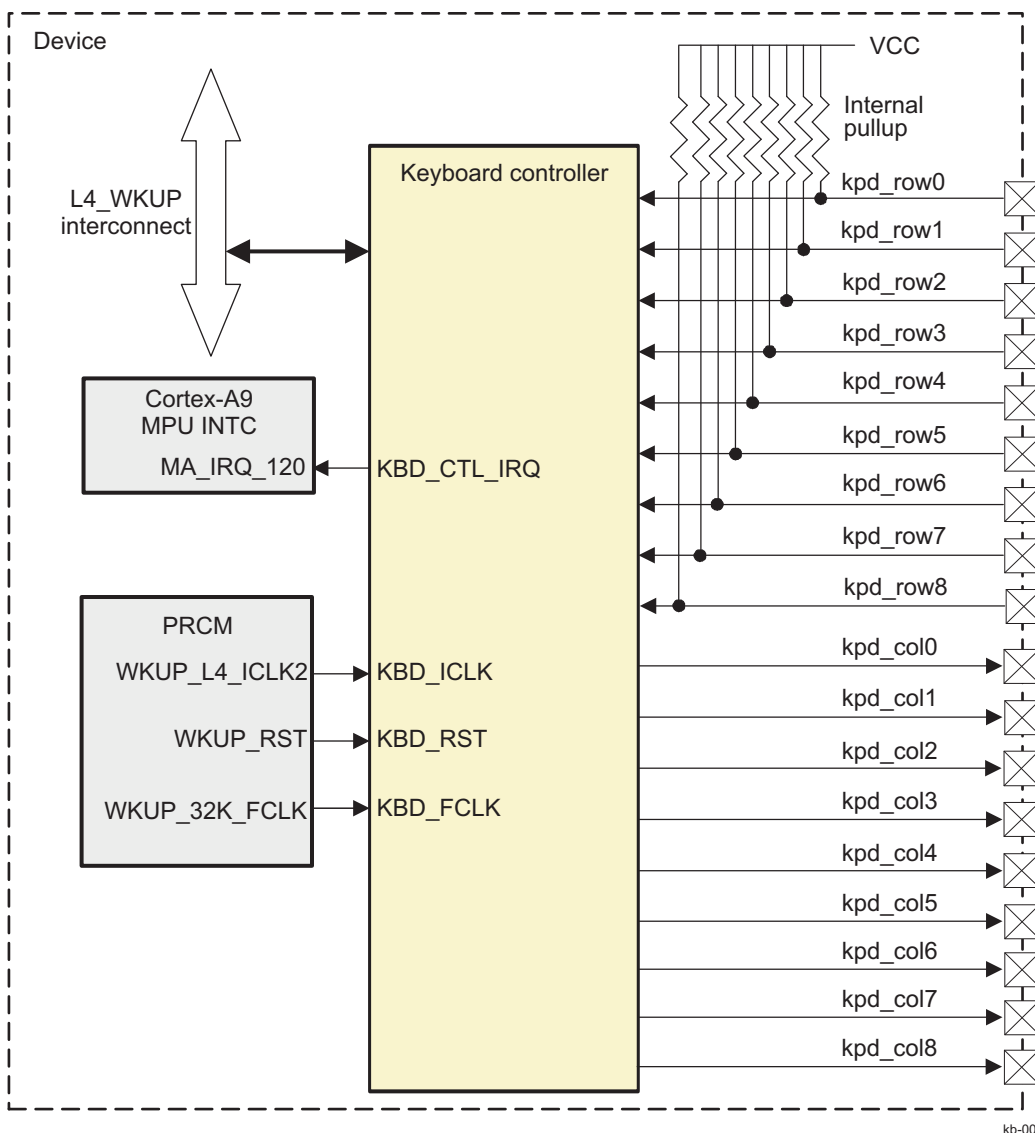

kb-007

NOTE: When using the keyboard controller with a smaller keypad (for example, 5 × 5), unused rows must be tied high to prevent disturbing the scanning process. Normally, all rows must be pulled up internally at the I/O cells of the device.

26.3 Keyboard Controller Integration

Figure 26-4 shows keyboard controller integration.

Figure 26-4. Keyboard Controller Integration

The control module must enable the internal pullups of the GPIO cells for all keypad rows (for more information about configuration, see [Chapter 18, Control Module](#)).

[Table 26-2](#) through [Table 26-4](#) summarize the integration of the module in the device.

Table 26-2. Integration Attributes

| Module Instance | Attributes | | |
|---------------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| KEYBOARD CONTROLLER | PD_WKUP | Yes | L4_WKUP |

Table 26-3. Clocks and Resets

| Clocks | | | | |

| KEYBOARD CONTROLLER | KBD_FCLK | WKUP_32K_FCLK | PRCM | 32-kHz functional clock. For information about power, reset, clock management (PRCM) clock gating and management, see Section 3.1.1.1.4, Clock Domain-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management . |
| KEYBOARD CONTROLLER | KBD_ICLK | WKUP_L4_ICLK2 | PRCM | L4-interconnect interface clock. For information about PRCM clock gating and management, see Section 3.1.1.1.4, Clock Domain-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management . |
| Resets | | | | |
| KEYBOARD CONTROLLER | KBD_RST | WKUP_RST | PRCM | Active low asynchronous general reset. For information about PRCM reset sources and distribution, see Section 3.1.1.1.4, Clock Domain-Level Clock Management , in Chapter 3, Power, Reset, and Clock Management . |

Table 26-4. Hardware Requests

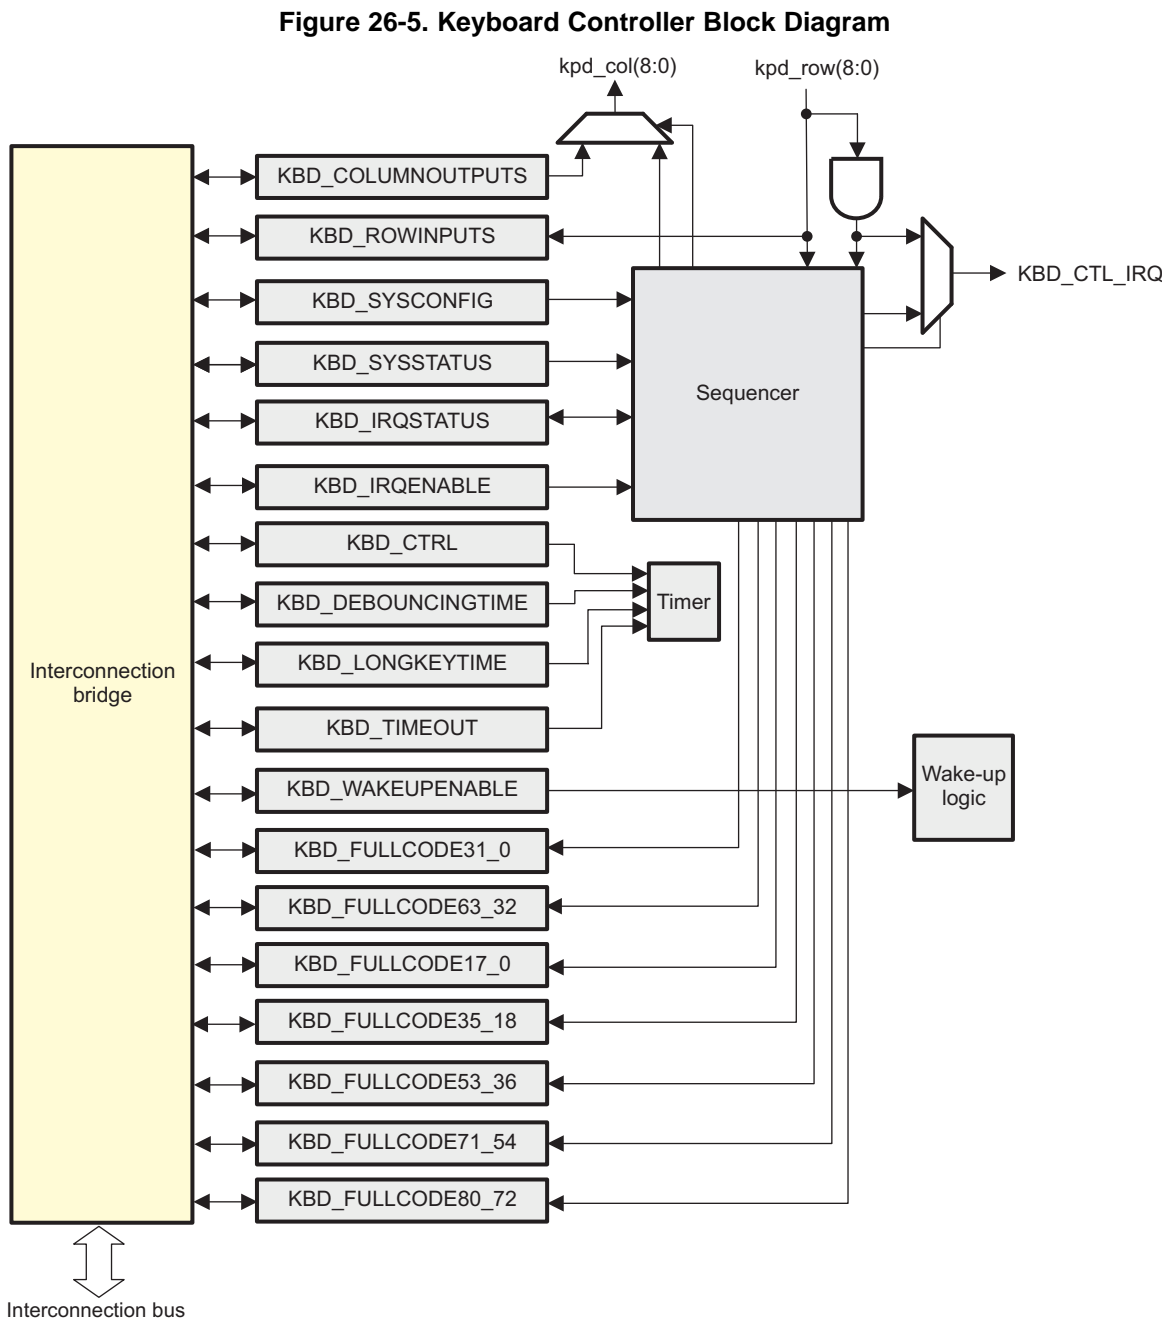

| Interrupt Requests | | | | |
|---------------------|--------------------|-------------------------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| KEYBOARD CONTROLLER | KBD_CTL_IRQ | MA_IRQ_120 | Cortex™-A9 INTC | Interrupt signal to the interrupt controller (INTC) of the MPU. For information about INTC interrupt control, see Chapter 17, Interrupt Controllers . |

NOTE: For the description of the interrupt source, see [Section 26.4.4, Interrupt Requests](#).

26.4 Keyboard Controller Functional Description

26.4.1 Keyboard Controller Block Diagram

Figure 26-5 shows the functional specification block diagram of the keyboard controller.

kb-004

The keyboard controller detects events issued on any key of the connected keyboard and generates an interrupt to alert the host processor. The built-in hardware-scan algorithm decodes the pressed keys, including multikey combinations.

To reduce MPU software overhead, the hardware performs detecting and decoding in the keyboard controller state-machine. However, hardware decoding can be deactivated so that software handles the scanning algorithm.

The value of the columns output is determined in the [KBD_COLUMNOUTPUTS\[8:0\]](#) KBC_REG bit field. To activate a keypad row-column connection, the corresponding bit must be 0b0.

The following sections describe subfunctions and subfunction interactions (control, data paths).

26.4.2 Keyboard Controller Software Reset

To perform a software reset, set the [KBD_SYSCONFIG\[1\]](#) SOFTRESET bit to 1. The [KBD_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [KBD_SYSCONFIG\[1\]](#) SOFTRESET bit is automatically reset. Software must ensure that the software reset completes before performing mailbox operations.

26.4.3 Keyboard Controller Power Management

[Table 26-5](#) describes the power-management features available for the keyboard controller.

NOTE: For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1.4, Clock Domain-Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 26-5. Local Power-Management Features

| Feature | Registers | Description |
|------------------------|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Clock autogating | KBD_SYSCONFIG[0] AUTOGATING | This bit allows local power optimization in the module by gating the KBD_ICLK clock upon interface activity, or gating KBD_FCLK upon internal activity. |
| Slave idle modes | KBD_SYSCONFIG[4:3] IDLEMODE | Force-idle, no-idle, and smart-idle modes are available. |
| Clock activity | KBD_SYSCONFIG[9:8] CLOCKACTIVITY | For configuration details, see Table 26-6 . |
| Master standby modes | N/A | N/A |
| Global wake-up enable | KBD_SYSCONFIG[2] ENAWAKEUP | This bit enables the wake-up feature at the module level. If smart-idle mode is selected, this bit provides the option of smart-idle wake-up-capable mode. |
| Wake-up sources enable | KBD_WAKEUPENABLE | This register holds one active-high enable bit per event source able to generate a wake-up signal. |

[Table 26-6](#) lists the clock activity settings.

Table 26-6. Clock Activity Settings

| KBD_SYSCONFIG [9:8] CLOCKACTIVITY Values | Clock State When Module is in IDLE State | | Features Available When Module is in IDLE State | Wake-Up Events |
|-------------------------------------------------------------------|---------------------------------------------|--------------------------|----------------------------------------------------|---------------------------------------------------|
| | KBD_ICLK | KBD_FCLK | | |
| 00 | OFF | OFF | None | The wake-up capability of the module is disabled. |
| 10 | OFF | ON | All | Asserting of wake-up signal |
| 01 | ON | OFF | None | The wake-up capability of the module is disabled. |
| 11 | ON | ON | All | Asserting of wake-up signal |

CAUTION

The PRCM module has no hardware means of reading the CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the keyboard controller CLOCKACTIVITY and keyboard controller clock PRCM control bits. For a description of the ClockActivity feature, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

26.4.4 Keyboard Controller Interrupt Requests

[Table 26-7](#) lists the event flags, and their mask, that can cause module interrupts.

Table 26-7. Events

| Event Flag | Event Mask | Description |
|-----------------------------------------------|--------------------------------------------------|-------------------------------|
| KBD_IRQSTATUS [3] MISS_EVENT | – | A miss event occurs. |
| KBD_IRQSTATUS [2] IT_TIMEOUT | KBD_IRQENABLE [2] IT_TIMEOUT_EN | A time-out event is detected. |
| KBD_IRQSTATUS [1] IT_LONG_KEY | KBD_IRQENABLE [1] IT_LONG_KEY_EN | A long-key event is detected. |
| KBD_IRQSTATUS [0] IT_EVENT | KBD_IRQENABLE [0] IT_EVENT_EN | An event is detected. |

26.4.5 Keyboard Controller Software Mode

The [KBD_CTRL](#)[1] NSOFTWARE_MODE bit selects software mode when it is set to 0.

In software mode, the keyboard controller internal sequencer, which performs automatic scanning and decoding, is disabled. Consequently, software must manually perform the scanning algorithm.

The scanning sequence is managed using the keyboard controller column outputs register ([KBD_COLUMNOUTPUTS](#)) and the keyboard controller row inputs register ([KBD_ROWINPUTS](#)). In this configuration, the keyboard interrupt is a logical ANDing of all bits of the [KBD_ROWINPUTS](#) register.

For more information about the software scan, see [Section 26.5.1, Keyboard Controller Low-Level Programming Model](#).

26.4.6 Keyboard Controller Hardware Decoding Modes**26.4.6.1 Functional Modes**

When running in hardware (default) decoding mode (the [KBD_CTRL](#)[1] NSOFTWARE_MODE bit is set to 1), the keyboard controller offers several functional modes; these modes are summarized in [Table 26-8](#). The keyboard interrupt depends on the configuration in the keyboard controller interrupt-enable register ([KBD_IRQENABLE](#)). If the event is enabled (bit 0 at 1), an interrupt is generated when the sequencer detects an event. Even if this interrupt is disabled, the flag status of the keyboard controller interrupt-status register ([KBD_IRQSTATUS](#)) is updated.

Table 26-8. Keyboard Controller Functional Modes

| Functional Mode | Associated Interrupt | Associated Timer Value | Description | Control |
|-----------------|----------------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| Keyboard event | Event interrupt | Debouncing value | Occurs when a key is pressed or released Always enabled | KBD_CTRL [8:5] bits must be set to 0 to disable all the other features. |
| Long key | Long-key interrupt | Long-key value | Used to detect a key that is pressed for a long time Should be associated with the long-key time-out function or repeat mode | KBD_CTRL [5] LONG_KEY bit |

Table 26-8. Keyboard Controller Functional Modes (continued)

| Functional Mode | Associated Interrupt | Associated Timer Value | Description | Control |
|-------------------|----------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| Repeat key | Long-key interrupt | Long-key value | Generates an interrupt every long-key delay No time-out can be associated. | KBD_CTRL [8] REPEAT_MODE bit |
| Empty time-out | Time-out interrupt | Empty time-out value | Interrupt generated if no key is pressed during an empty time-out period. | KBD_CTRL [6] TIMEOUT_EMPTY bit |
| Long-key time-out | Time-out interrupt | Long-key time-out value | Associated with the long-key function Generated after a long-key interrupt if no event occurs during a long-key time-out period | KBD_CTRL [7] TIMEOUT_LONG_KEY bit |

Each mode can be activated/deactivated by setting the corresponding bits (5, 6, 7, and 8) in the [KBD_CTRL](#) register with the appropriate values (for more information, see [Section 26.6, Keyboard Controller Register Manual](#)).

26.4.6.2 Keyboard Controller Timer

As described in the previous section, each functional mode is associated with a timer value. Depending on the selected mode, the keyboard controller timer is loaded with the corresponding value as set in the related registers:

- [KBD_DEBOUNCINGTIME](#)
- [KBD_KEYLONGTIME](#)
- [KBD_TIMEOUT](#)

[Table 26-9](#) summarizes the values of the keyboard controller timer.

Table 26-9. Keyboard Controller Timer Values

| Timer Value | Associated Register Field | Description |
|--------------------|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Debouncing time | KBD_DEBOUNCINGTIME [5:0] DEBOUNCING_VALUE | To remove the effects of glitches when an event occurs on the keyboard, the controller waits for a debouncing period before taking a snapshot of the current state on the keyboard matrix. The timer is loaded with the debouncing time value after each detected event on the keyboard matrix. An event interrupt is generated after this delay. |
| Long-key time | KBD_KEYLONGTIME [11:0] LONG_KEY_VALUE | This is the delay before generating a long-key interrupt after an event interrupt. If the long-key mode is selected, the timer is loaded with the long-key time value after an event interrupt is generated. In repeat mode, the timer is reloaded with the same value after a long-key interrupt, and starts to count down again. |
| Long-key time-out | KBD_TIMEOUT [15:0] TIMEOUT_VALUE | The timer is loaded with the time-out value and then a long-key interrupt is generated and starts to count down. When it reaches 0, a time-out interrupt is generated and the keyboard controller returns to its IDLE state. This long-key time-out does not work in repeat mode. |
| Empty key time-out | KBD_TIMEOUT [15:0] TIMEOUT_VALUE | The time-out interrupt occurs if no key is pressed during this delay. The keyboard controller then returns to IDLE state. |

The timer countdown period depends on three factors:

- The loaded value as set in:
 - [KBD_DEBOUNCINGTIME](#)
 - [KBD_KEYLONGTIME](#)
 - [KBD_TIMEOUT](#)
- The value of the prescale clock timer as set in the [KBD_CTRL](#)[4:2] PTV bit field. This programmable clock divider allows the reduction of the clock frequency used by the timer.
- The frequency of the keyboard controller functional clock (32 kHz)

The period is calculated as follows:

$$T_{\text{period}} = (T_{\text{value}} + 1) \times 2^{\text{PTV} + 1} \times T_{\text{clk}}$$

Where:

T_{value} is the value stored in the [KBD_DEBOUNCINGTIME](#), [KBD_KEYLONGTIME](#), or [KBD_TIMEOUT](#) register.

PTV is the value of the [KBD_CTRL\[4:2\]](#) register PTV bit field.

T_{clk} is the period of the 32-kHz functional clock; that is, 31.25 μs .

The [KBD_CTRL\[4:2\]](#) PTV bit field determines the division factor of the timer clock. [Table 26-10](#) lists the divider rates.

Table 26-10. Timer Prescale Values

| KBD_CTRL[4:2] PTV Value | Divisor |
|-----------------------------------------|---------|
| 0 | 2 |
| 1 | 4 |
| 2 | 8 |
| 3 | 16 |
| 4 | 32 |
| 5 | 64 |
| 6 | 128 |
| 7 | 256 |

NOTE: The timer minimum period is 62.5 μs ; its maximum period is 524.288 seconds.

CAUTION

To prevent undefined results, the [KBD_CTRL\[4:2\]](#) PTV bit field must not be changed when the timer is running.

The timer value registers ([KBD_DEBOUNCINGTIME](#), [KBD_KEYLONGTIME](#), and [KBD_TIMEOUT](#)) can be updated at any time, whether or not the timer is running. Nevertheless, the timer is updated only on the fly for the long-key time value. The new debouncing and time-out values are loaded only on the next load. Depending on the updated register, two cases can occur:

- The [KBD_KEYLONGTIME](#) register is updated; the new value stored in the [KBD_KEYLONGTIME](#) register is loaded into the timer when the register is written. If the timer is already counting down when [KBD_KEYLONGTIME](#) is updated, it counts down from the new value loaded in [KBD_KEYLONGTIME](#).
- The [KBD_DEBOUNCINGTIME](#) or [KBD_TIMEOUT](#) register is updated; the new value is considered only when the next timer loads. If the timer is counting down when the registers are updated, the timer continues counting down from the previous value and is loaded with the new one on the next load.

Regardless of the timer state (stopped, counting down any of the values previously described, etc.), when a new event occurs on the keyboard, the timer is stopped and loaded with the debouncing time value. It then starts counting down.

26.4.6.3 State-Machine Status

To facilitate debugging, each state of the state-machine is coded in a register that indicates the current state of the machine. [Table 26-11](#) lists the corresponding codes.

Table 26-11. State-Machine Values

| KBD_STATEMACHINE[3:0] Value | Description |
|------------------------------------|------------------------------|
| 0x0 | Idle |
| 0x1 | Scanning |
| 0x2 | Load timer debouncing |
| 0x3 | Test timer debouncing |
| 0x4 | Generated interrupt event |
| 0x6 | Load timer long key |
| 0x7 | Test timer long key |
| 0x8 | Generated interrupt long key |
| 0x9 | Load timer time-out |
| 0xA | Test timer time-out |
| 0xB | Generated interrupt time-out |
| 0xF | Other |

26.4.6.4 Keyboard Controller Interrupt Generation

26.4.6.4.1 Interrupt-Generation Scheme

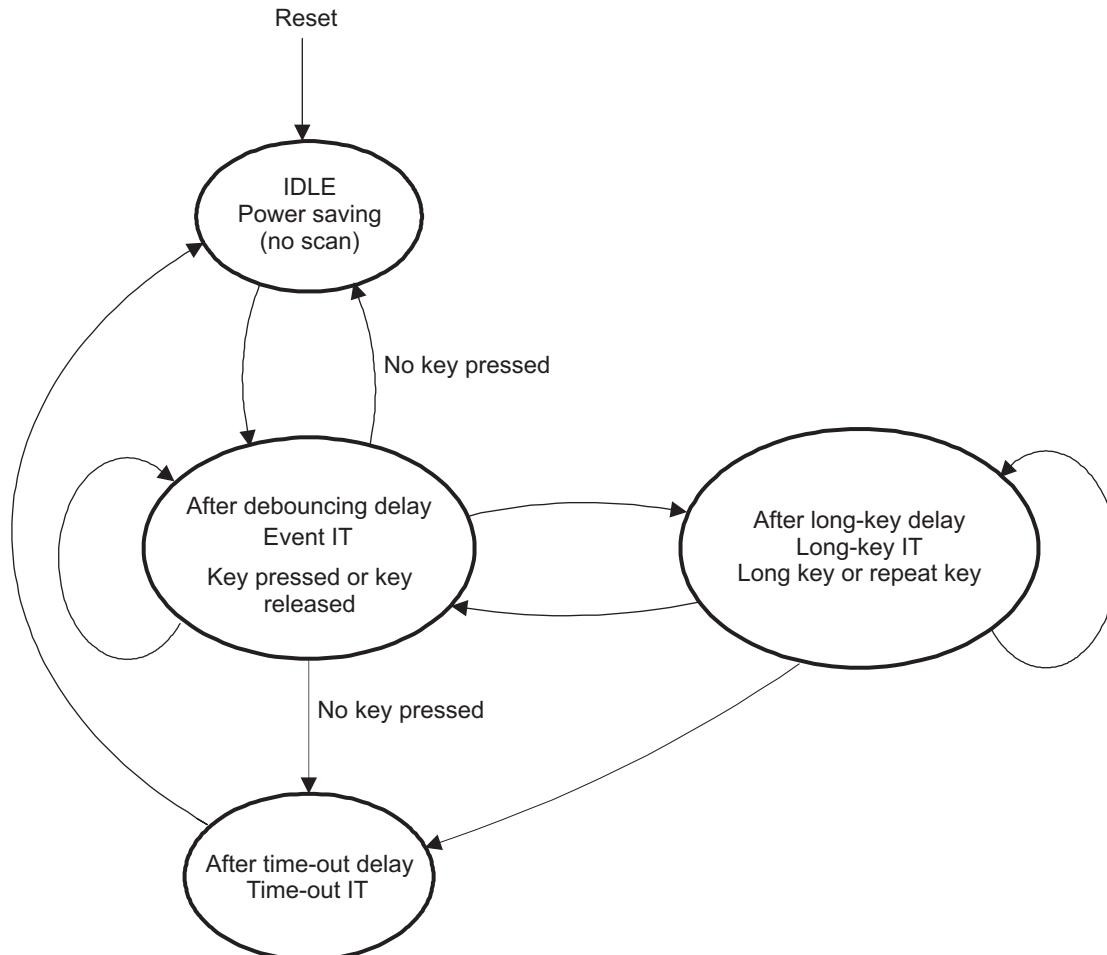

The keyboard controller generates one interrupt signal to external INTC KBD_CTL_IRQ. Each functional mode generates dedicated interrupt events (logged in the [KBD_IRQSTATUS](#) register) that can be masked or unmasked using the [KBD_IRQENABLE](#) register.

The [KBD_IRQSTATUS](#) register is updated when the selected functional mode generates an interrupt event. However, the KBD_CTL_IRQ signal is asserted on the related event only when the corresponding bit is set in the [KBD_IRQENABLE](#) register.

NOTE: To reset the interrupt status bit, 1 must be written to the appropriate bit of the [KBD_IRQSTATUS](#) read/write register.

[Figure 26-6](#) shows the different interrupt events generated in each keyboard controller functional mode and details the relationships between them.

NOTE: Depending on the selected mode, some interrupt events cannot be generated.

Figure 26-6. Functional Modes and Related Interrupt Events

kb-005

While running in hardware-decoding mode, the keyboard controller performs automatic scans when not in IDLE state. When a key-press event occurs on the keyboard matrix, the keyboard controller leaves IDLE state and an interrupt event (the [KBD_IRQSTATUS\[0\] IT_EVENT](#) bit) is set after the timer counts down the debouncing delay. An IT_EVENT is generated when a key is pressed or released.

NOTE: An IT_EVENT is generated regardless of the selected functional mode. If no time-out is set and no more keys are pressed, the keyboard controller returns to IDLE state.

If long-key detection mode is set when the timer counts down the long-key delay, an interrupt long key (the [KBD_IRQSTATUS\[1\] IT_LONG_KEY](#) bit) is generated. If the repeat mode is set, the IT_LONG_KEY interrupt is generated periodically every long-key delay.

A time-out can also be set in event detection or long-key detection mode. In this case, a time-out interrupt (the [KBD_IRQSTATUS\[2\] IT_TIMEOUT](#) bit) is generated after the time-out delay timer expires. After such an interrupt, the keyboard controller always returns to IDLE state.

NOTE: No time-out can be set in repeat mode. Only a keyboard event can stop the periodic interrupt generation.

26.4.6.4.2 Keyboard Buffer and Missed Events (Overrun Feature)

The keyboard controller has an overrun feature: A dedicated buffer allows the keyboard controller to memorize two successive events. If two successive events occur before a read is performed, the second event is stored and a second interrupt is generated when the first interrupt is cleared, allowing two consecutive key events to be received.

If a third event occurs before the first event is treated, a missed event interrupt (the `KBD_IRQSTATUS[3] MISS_EVENT` bit) is generated to report the lost event.

NOTE: The `MISS_EVENT` interrupt is not routed to the `KBD_CTL_IRQ` signal; software must check the `KBD_IRQSTATUS[3] MISS_EVENT` bit to detect any missed events.

26.4.7 Keyboard Controller Key Coding Registers

The keyboard controller matrix pressed keys state (indicating which columns/rows are connected) is reflected in the `KBD_FULLLCODE17_0` to `KBD_FULLLCODE80_72` registers, as shown in [Figure 26-7](#). These registers are updated only when interrupt event status is inactive to prevent a lost event.

NOTE: The `KBD_FULLLCODE31_0` and `KBD_FULLLCODE63_32` registers, which are limited to supporting keyboards of a maximum 8 x 8 array size, can be used for back-to-back software compatibility.

Figure 26-7. Key Coding Registers

kb-006

Each of the 9 x 9 keyboard size supporting registers (`KBD_FULLLCODE17_0` up to `KBD_FULLLCODE71_54`) stores the state of two keyboard rows. The `KBD_FULLLCODE80_72` register stores the state of the last row, R8:

- The `KBD_FULLLCODE17_0` register code rows 0, 1 (row 0 is coded between bits 0 and 8, row 1 is coded between bits 16 and 24)
- The `KBD_FULLLCODE35_18` register code rows 2, 3 (row 2 is coded between bits 0 and 8, row 3 is coded between bits 16 and 24)
- The `KBD_FULLLCODE53_36` register code rows 4, 5 (row 4 is coded between bits 0 and 8, row 5 is coded between bits 16 and 24)
- The `KBD_FULLLCODE71_54` register code rows 6, 7 (row 6 is coded between bits 0 and 8, row 7 is coded between bits 16 and 24)
- The `KBD_FULLLCODE80_72` register code row 8 (row 8 is coded between bits 0 and 8)

In each of these registers (excluding `KBD_FULLLCODE80_72`):

- Bit 0 corresponds to column(0) – row (i) key, ... , bit 8 corresponds to column(8) – row (i) key.
- Bits from 9 to 15 are reserved.
- Bit 16 corresponds to column(0) – row (i+1) key, ... , bit 24 corresponds to column (8) – row (i+1) key.

- Bits 31 to 25 are reserved, where $i = 0, 2, 4, 6$.

In register [KBD_FULLCODE80_72](#) bit 0 corresponds to column (0) – row (8) key, ..., the bit 8 corresponds to column (8) – row (8) key, and the remaining bits (from 9 to 31) are reserved.

Each of the 8×8 -keyboard size supporting registers ([KBD_FULLCODE31_0](#) and [KBD_FULLCODE63_32](#)) stores the state of four keyboard rows:

- The [KBD_FULLCODE31_0](#) register code rows 0, 1, 2, and 3 (row 0 is coded between bits 0 and 7, row 1 is coded between bits 8 and 15, row 2 is coded between bits 16 and 23, and row 3 is coded between bits 24 and 31)
- The [KBD_FULLCODE63_32](#) register code rows 4, 5, 6, and 7 (row 4 is coded between bits 0 and 7, row 5 is coded between bits 8 and 15, row 6 is coded between bits 16 and 23, and row 7 is coded between bits 24 and 31)

In these registers:

- [KBD_FULLCODE31_0](#)[0] corresponds to column (0) – row (0) key, ..., [KBD_FULLCODE31_0](#)[7] corresponds to column (7) – row (0).
- [KBD_FULLCODE31_0](#)[8] corresponds to column (0) – row (1) key, ..., [KBD_FULLCODE31_0](#)[15] corresponds to column (7) – row (1).
- [KBD_FULLCODE31_0](#)[16] corresponds to column (0) – row (2) key, ..., [KBD_FULLCODE31_0](#)[23] corresponds to column (7) – row (2).
- [KBD_FULLCODE31_0](#)[24] corresponds to column (0) – row (3) key, ..., [KBD_FULLCODE31_0](#)[31] corresponds to column (7) – row (3).
- [KBD_FULLCODE63_32](#)[0] corresponds to column (0) – row (4) key, ..., [KBD_FULLCODE63_32](#)[7] corresponds to column (7) – row (4).
- [KBD_FULLCODE63_32](#)[8] corresponds to column (0) – row (5) key, ..., [KBD_FULLCODE63_32](#)[15] corresponds to column (7) – row (5).
- [KBD_FULLCODE63_32](#)[16] corresponds to column (0) – row (6) key, ..., [KBD_FULLCODE63_32](#)[23] corresponds to column (7) – row (6).
- [KBD_FULLCODE63_32](#)[24] corresponds to column (0) – row (7) key, ..., [KBD_FULLCODE63_32](#)[31] corresponds to column (7) – row (7).

NOTE: The keyboard fullcode registers are not updated in software mode.

NOTE: When using a smaller keyboard (for example, 5×5 or 4×4), the bits of the unused columns/rows are not used either.

26.4.8 Keyboard Controller Register Access

26.4.8.1 Write Registers Access

The keyboard module uses a posted-write scheme to update any internal registers. This means the write transaction is immediately acknowledged on the L4 interface, although the effective write operation occurs later due to a resynchronization in the functional clock domain. This has the advantage of not stalling the interconnect system or the CPU that requested the write transaction. For each functional register, a pending bit is provided that is set if there is a pending write access to this register. The pending bits are accessible in the keyboard pending write register ([KBD_PENDING](#)).

In this mode, it is mandatory that the CPU checks the pending bits before any write access in the functional registers. If a write is attempted to a register with a previous access pending, the previous access is discarded without notice (this can also lead to unexpected results).

A register read following a posted write (on the same register) may not read the previous write value if the write posted process is not complete. Software synchronization must be used to avoid noncoherent read.

This posted period is defined as the interval between the posted write access request and the reset of the pending bit in the [KBD_PENDING](#) register, and can be quantified:

T (reset posted bit maximum) = $3 \times T_{iclk} + 3 \times T_{funcclk}$

The time it takes to accomplish the writing is:

T (write accomplish maximum) = $1 \times T_{iclk} + 3 \times T_{funcclk}$

where:

T_{iclk} is the L4 interface clock period, and $T_{funcclk}$ is the functional clock period.

26.4.8.2 Read Registers Access

The keyboard module uses a posted-read scheme for reading any internal register. The read transaction is immediately acknowledged on the L4 interface. The value of the functional register to be read must be previously synchronized. This has the advantage of not stalling the interconnect system or the CPU that requested the read transaction.

The posted-read scheme can be used only if $\text{Freq}(\text{KBD_FCLK}) < \text{Freq}(\text{KBD_ICLK})/4$.

26.5 Keyboard Controller Programming Guide

26.5.1 Keyboard Controller Low-Level Programming Models

This section describes the low-level hardware programming sequences for the configuration and use of the module.

26.5.1.1 Global Initialization

26.5.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements for initializing the surrounding modules when the keyboard module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the keyboard. For more information, see [Section 26.2, Keyboard Controller Environment](#), and [Section 26.3, Keyboard Controller Integration](#).

[Table 26-12](#) describes the global initialization of surrounding modules.

Table 26-12. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRCM | The module interface (WKUP_L4_ICLK2) and functional (WKUP_32K_FCLK) clocks must be enabled. See , Clock Management Global Initialization , in Chapter 3, Power, Reset, and Clock Management . |
| Cortex-A9 MPU INTC | Interrupt request KBD_CTL_IRQ from the keyboard must be unmasked. For more information, see Chapter 17, Interrupt Controllers . |
| Control module | The PAD CONFIG registers must be configured in to map the keyboard interface signals on the device pins through the multiplexers (mux mode 0 must be switched on) to determine the signal directions and to enable the internal pullups of the GPIO cells for all the keyboard rows. For more information about configuration, see Section 18.4.8, Pad Functional Multiplexing and Configuration , and Section 25.2.1, General-Purpose Interface as a Keyboard interface . |

26.5.1.1.2 Keyboard Controller Global Initialization

26.5.1.1.2.1 Main Sequence – Keyboard Controller Global Initialization

This procedure initializes the keyboard controller after a POR or software reset (see [Table 26-13](#)).

Table 26-13. Keyboard Controller Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|------------|
| Configure the parameters of the L4 interface and enable the clock activity. | KBD_SYSCONFIG | 0x00000– |
| Configure the debouncing time of filtering the glitches on pressing or releasing key. | KBD_DEBOUNCINGTIME[5:0] DEBOUNCING_VALUE | 0x– |
| Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value). | KBD_KEYLONGTIME[11:0] LONG_KEY_VALUE | 0x– |
| Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt). | KBD_TIMEOUT[15:0] TIMEOUT_VALUE | 0x– |
| Define the logical value of the column outputs (KEYPAD configuration) (logical 0 bit = active column-row). | KBD_COLUMNOUTPUTS[8:0] KBC_REG | 0x– |
| Perform the functional configuration of the keyboard module and the prescale clock timer value. | KBD_CTRL | 0x00000– |
| Clear the interrupt-status register. | KBD_IRQSTATUS | 0x0000000F |
| Enable (0b1)/disable (0b0) certain keyboard events for generating an interrupt request. | KBD_IRQENABLE[2:0] IT_..._EN | 0x– |

Table 26-13. Keyboard Controller Global Initialization (continued)

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------------------------------------------------------------------------|----------------------------------------------------|-------|
| Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request. | KBD_WAKEUPENABLE [2:0] WUP_..._ENA | 0x– |

26.5.1.2 Operational Modes Configuration

26.5.1.2.1 Keyboard Controller in Hardware Decoding Mode (Default Mode)

26.5.1.2.1.1 Main Sequence – Keyboard Controller Hardware Mode

After reset, all available functional modes are disabled, except detect-event mode, which is always active. [Table 26-14](#) describes the keyboard controller hardware mode.

Table 26-14. Keyboard Controller Hardware Mode

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| Activate the internal keyboard controller sequencer by setting the bit. | KBD_CTRL [1] NSOFTWARE_MODE | 0b1 |
| Select the functional mode by setting its corresponding bit to 1. | KBD_CTRL [8:5] | 0x– |
| Configure the duration of a key press to allow shortcut detection (desired value of the long-key interrupt or repeat mode value). | KBD_KEYLONGTIME [11:0] LONG_KEY_VALUE | 0x– |
| Configure the period of the long inactivity on the keyboard (desired value of the time-out interrupt). | KBD_TIMEOUT [15:0] TIMEOUT_VALUE | 0x– |
| Configure the debouncing time of filtering the glitches on pressing or releasing key. | KBD_DEBOUNCINGTIME [5:0] DEBOUNCING_VALUE | 0x– |
| Clear the interrupt-status register. | KBD_IRQSTATUS | 0x0000000F |
| Enable (by writing 1)/disable (by writing 0) certain keyboard event for generating an interrupt request | KBD_IRQENABLE [2:0] IT_..._EN | 0x– |
| Unmask (0b1)/mask (0b0) the expected source of wake-up event that generates a wake-up request. | KBD_WAKEUPENABLE [2:0] WUP_..._ENA | 0x– |
| Wait for the KBD_CTL_IRQ interrupt signal assertion. | | |
| Read the interrupt-status register to determine which event caused the interrupt. | KBD_IRQSTATUS | |
| Read the KBD_FULLCODE17_0 to KBD_FULLCODE80_72 registers (or 8 × 8 keyboard-size-supporting KBD_FULLCODE31_0 and KBD_FULLCODE63_32 registers) to determine which key matrix combination was pressed. | KBD_FULLCODE17_0 [ROWi bits] (where i = 0 to 1) up to KBD_FULLCODE71_54 [ROWi bits] (where i = 6 to 7); KBD_FULLCODE80_72 [ROWi bits] (where i = 8); (or KBD_FULLCODE31_0 [j] FULL_CODE_31_0 and KBD_FULLCODE63_32 [k] FULL_CODE_63_32 bits (where j = 0 to 31, k = 32 to 63) | |
| Clear the corresponding bit(s) in the interrupt-status register by writing logical 1. | KBD_IRQSTATUS | 0x1 |

NOTE: The long-key detection mode and the repeat mode cannot be used simultaneously, because they share the same interrupt status bit and are mutually exclusive. Software must ensure that only one of these modes at a time is selected.

NOTE: All interrupts are disabled on reset.

NOTE: When two events occur successively before the first event is read, the second interrupt is generated when the first interrupt is cleared. When more than two events in a row occur, the [KBD_IRQSTATUS\[3\] MISS_EVENT](#) bit is set. Software must check this bit, which is not reflected on the [KBD_CTL_IRQ](#) line.

NOTE: The keyboard controller uses a posted-write scheme to update any internal register. Software must read the pending write status bits to ensure that the next write access is not discarded because of ongoing write synchronization. For more information, see [Section 26.4.8.1, Write Registers Access](#).

26.5.1.2.2 Keyboard Controller Software Scanning Mode

26.5.1.2.2.1 Main Sequence – Keyboard Controller Software Mode

[Table 26-15](#) describes the keyboard controller software mode.

Table 26-15. Keyboard Controller Software Mode

| Step | Register/Bit Field/Programming Model | Value D |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|---------|
| Deactivate the internal keyboard controller sequencer by clearing the bit. | KBD_CTRL[1] NSOFTWARE_MODE | 0b0 |
| Enable the event interrupt by setting the bit. | KBD_IRQENABLE[0] IT_EVENT_EN | 0b1 |
| Wait for the KBD_CTL_IRQ interrupt signal assertion. Begin the software scan when the interrupt signal is asserted: | | |
| 1) Disable all columns to drive a logical 0 on the kpd_col[8:0] output by writing 0xFF. (logical 1 bit = inactive column-row) | KBD_COLUMNOUTPUTS[8:0] KBC_REG | 0xFF |
| 2) Drive kpd_col(i) output, (where $i = 0$ to 8), to 0 to capture a pressed-key-event, at the corresponding row input. | KBD_COLUMNOUTPUTS[i] KBC_REG (where $i = 0$ to 8) | 0b0 |
| 3) Read the KBR_LATCH bit field of the KBD_ROWINPUTS register to determine which is the pressed key. IF: KBR_LATCH k-bit = 0, where $k = 0$ to 8 Then, the corresponding k-row is connected to the column being enabled. END IF | KBD_ROWINPUTS[8:0] KBR_LATCH | |
| Repeat steps 2) and 3) for all existing columns. | KBD_WAKEUPENABLE[2:0] WUP_..._ENA | 0x– |

NOTE: In software mode, during the manual keyboard scan, an interrupt is generated when a pressed key is detected.

26.5.1.2.3 Using the Timer

For information about programming the keyboard controller timer, see [Section 26.4.6.2, Keyboard Controller Timer](#).

26.5.1.2.4 State-Machine Status Register

To see the state of the state-machine, see [Section 26.4.6.3, State-Machine Status](#).

26.5.1.3 Keyboard Controller Events Servicing

[Table 26-16](#) lists the keyboard controller event servicing.

Table 26-16. Keyboard Controller Event Servicing

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------|--------------|
| Clear all eventual previous indications of treated interrupts; write the IRQSTATUS register: | KBD_IRQSTATUS | 0x0000000F |
| Enable the desired sources of interrupt by writing in: | KBD_IRQENABLE | 0x0000000- |
| Unmask (enable) the desired sources of interrupt by writing logical 1 in the desired bit fields. | KBD_WAKEUPENABLE | 0x0000000- |
| When event occurs: | | |
| Read the status register. | KBD_IRQSTATUS | |
| IF: KBD_IRQSTATUS [3] MISS_EVENT = 1 | Start the interrupt handler for missed event. | |
| ELSIF: KBD_IRQSTATUS [2] IT_TIMEOUT = 1 | Start the interrupt handler for timeout event. | |
| ELSIF: KBD_IRQSTATUS [1] IT_LONG_KEY = 1 | Start the interrupt handler for long key pressed event. | |
| ELSIF: KBD_IRQSTATUS [0] IT_EVENT = 1 | Start the interrupt handler for pressed key event. | |
| ENDIF | | |
| Wait for the execution of the corresponding interrupt handler. | Interrupt controller of the MPU | |
| Clear the corresponding IRQ status register bits by writing 1 there. | KBD_IRQSTATUS | 0x0000000- |
| Disable the corresponding sources of interrupt if needed by writing 0 at the corresponding bit fields. | KBD_IRQENABLE or KBD_WAKEUPENABLE | 0x0000000- |

Initialization

This chapter introduces the steps in the general-purpose (GP) multimedia device initialization.

| Topic | Page |
|-----------------------------------------------------|-------------|
| 27.1 Initialization Overview | 5605 |
| 27.2 Preinitialization | 5607 |
| 27.3 Reset Sequences | 5624 |
| 27.4 Device Initialization by ROM Code | 5625 |
| 27.5 Services for HLOS Support | 5692 |

27.1 Initialization Overview

This chapter provides an overview of the requirements for initializing the device from power-on to OS/application execution. It provides an overview of the overall initialization process, including hardware- and software-related steps, a general overview of the ROM code operational requirements, and the behavior expectations.

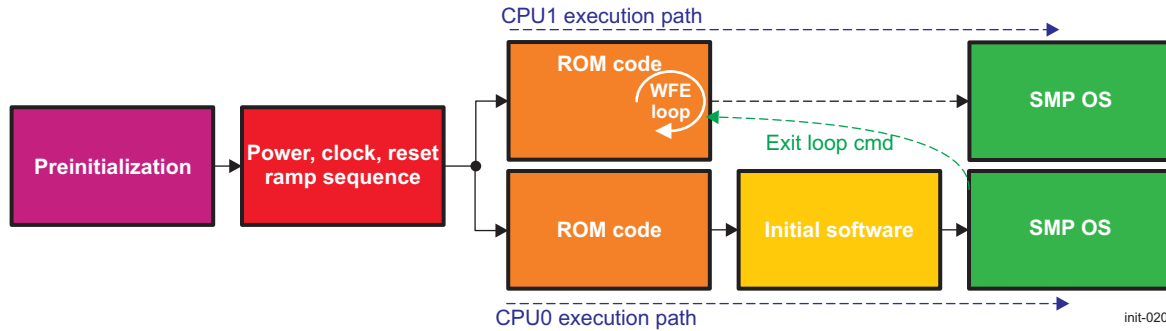

27.1.1 Terminology

- **Bootstrap:** Initial software launched by the ROM code during the memory booting phase
- **Configuration Header (CH):** Optional structure, that precedes the initial software and allows the redefinition of the ROM code default settings.
- **Downloaded software:** Initial software downloaded into the internal static RAM (SRAM) by the ROM code during the peripheral booting phase
- **eFuse:** A one-time programmable memory location usually set at the factory
- **Flash loader:** Downloaded software launched by the ROM code in preflashing. It also programs an image in external memories.
- **GP device:** General-purpose device
- **Initial software:** Software executed by any of the ROM code mechanisms (memory booting or peripheral booting). Initial software is a generic term for bootstrap and downloaded software.
- **Memory booting:** ROM code mechanism that consists of executing initial software from external memory
- **Master CPU:** The ARM Cortex™-A9 MPCore™ CPU for which CPU-ID is 0. It configures the multicore platform and starts the ROM code to ensure device booting from a mass storage memory (memory booting) or a peripheral interface (peripheral booting).
- **Peripheral booting:** ROM code mechanism that consists of polling selected interfaces, downloading, and executing initial software (in this case, downloaded software) in the internal RAM.
- **Permanent booting device:** Memory device containing, by default, the image to be executed during the booting sequence. It is the default memory booting device. The permanent booting device is used after warm reset if no software booting configuration is programmed.
- **Preflashing:** A specific case of peripheral booting where the ROM code mechanism is used to program the external flash memory
- **ROM Code:** The on-chip software in OMAP™ ROM that implements booting
- **Save-And-Restore (SAR RAM) memory:** On-chip RAM memory that is not cleared after warm resets or wake-ups from low-power modes
- **Slave CPU:** The ARM Cortex-A9 MPCore CPU for which CPU-ID is 1. It is brought to the wait-for-event (WFE) state by the ROM code, waiting to be woken up by the master CPU.
- **Software booting configuration:** A logical structure stored in the SAR memory that allows the redefinition of the ROM code default settings when booting after a warm reset

27.1.2 Initialization Process

[Figure 27-1](#) is an overview of the initialization process and its steps:

- **Preinitialization:** Power, clock, and control connections must be present, and the boot configuration pins must be held at the desired logical levels.
- **Power/clock/reset ramp sequence:** Specific sequence that is applied by the power-management chip
- **ROM code:** Responsible for finding/downloading and for executing the initial software by using the master CPU
- **Initial software:** Software that prepares and passes control to application software or to the high-level operating system (HLOS)
- **Symmetric multiprocessing (SMP)-capable HLOS** or application (primarily for diagnostics)

Figure 27-1. Initialization Process

The first two steps in the initialization process are hardware-oriented; however, they require understanding of the process of configuring these system interface pins (balls on the device), which have software-configurable functionality. This configuration is an essential part of the chip configuration and is application-dependent. This chapter discusses these pins and the associated configuration registers that are vital to the correct initialization of the device.

27.2 Preinitialization

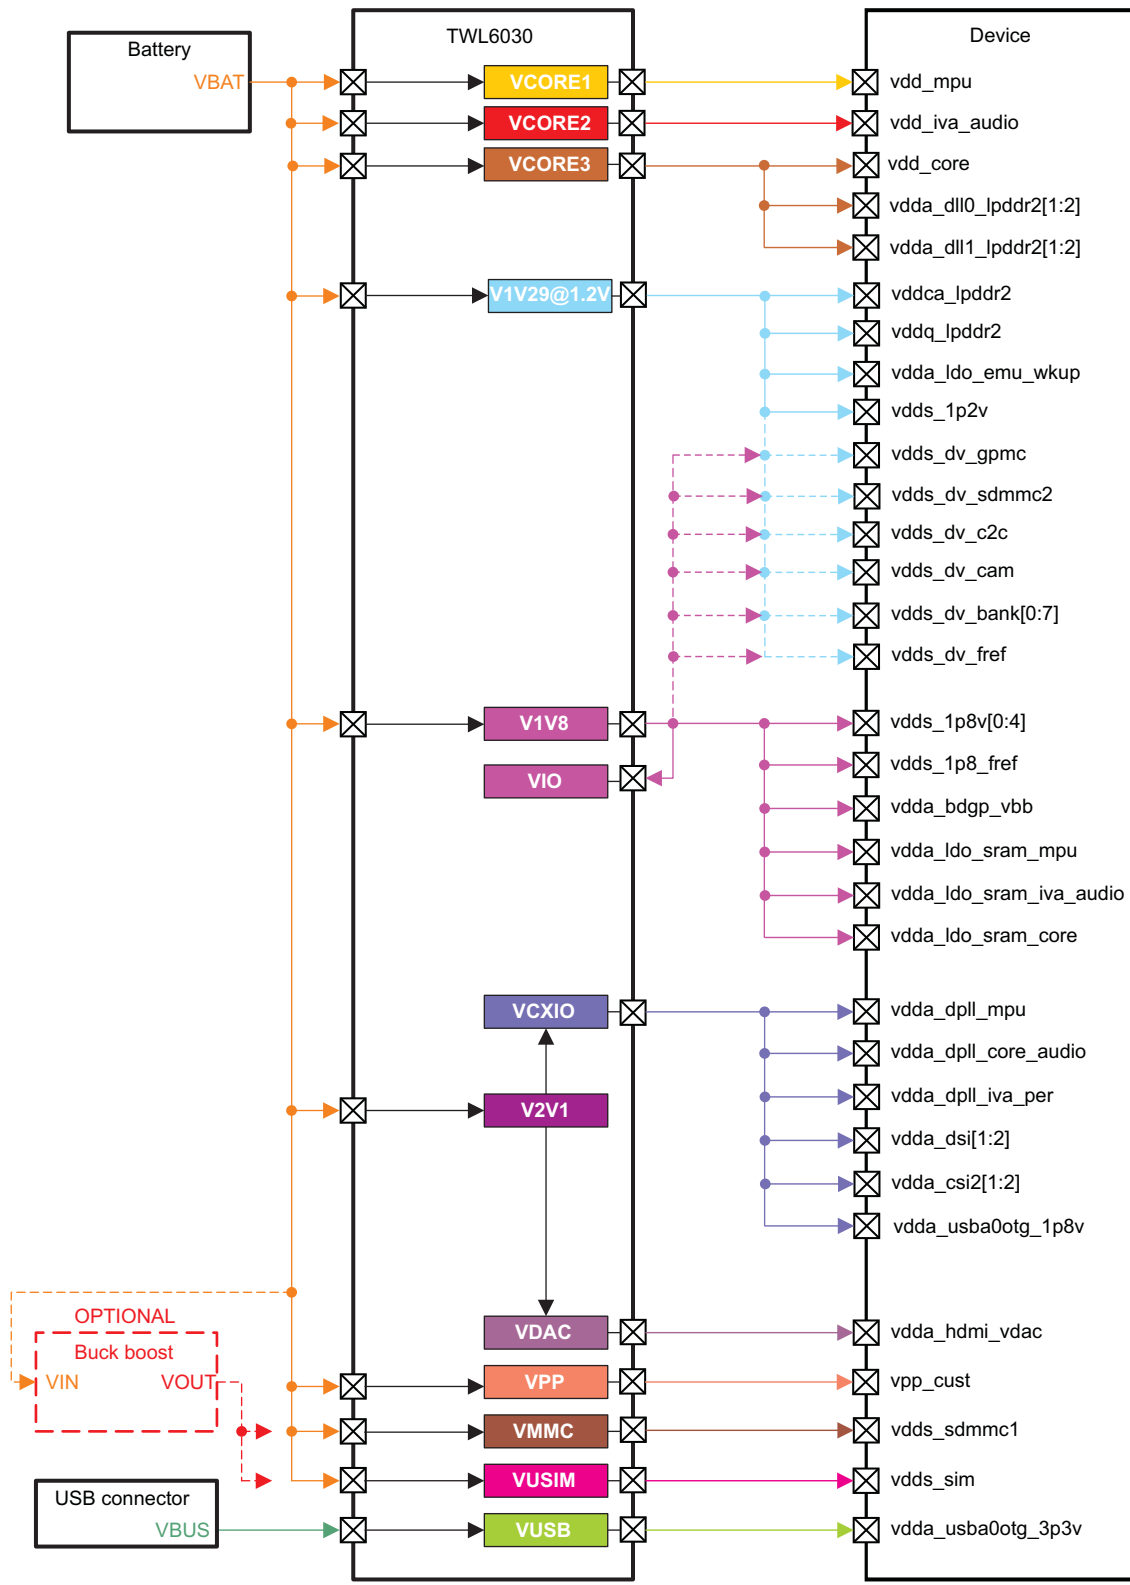

To accomplish a successful boot-up operation with a general-purpose (GP) device, certain hardware configuration settings must be in place. Clock, reset, and power connections, as well as pins involved in setting the boot memory space for the master CPU, must be connected and driven correctly for successful initialization of the device. The following sections describe the specific requirements for the preinitialization stage.

27.2.1 Power Requirements

The device can be supplied by an external power-management integrated circuit (IC). TI provides a global solution with the device connected to the TWL6030 power-management/TWL6040 audio codec IC.

[Figure 27-2](#) shows the power connections between the multimedia device and the TWL6030 power IC.

Figure 27-2. Power Supply Connections

init-002

NOTE: Figure 27-2 is an example of power connections between the device and the TWL6030. These connections depend on the actual application.

Table 27-1 describes the device power pins.

Table 27-1. Device Power Pins ⁽¹⁾

| vdda_dppll_iva_per | <ul style="list-style-type: none"> ADPLL PER and ADPLL IVA |
| vdda_dppll_core_audio | <ul style="list-style-type: none"> ADPLL CORE and ADPLL ABE |
| vdda_dppll_mpu | <ul style="list-style-type: none"> DPLL MPU |
| vdda_ldo_sram_mpu | Internal MPU SRAM LDO |

⁽¹⁾ The package-on-package (POP) device provides feedthroughs from the bottom of the package to the POP interface. Among these feedthroughs (FEEDTHROUGH balls), several provide power to the top memory device. The correct power supply to the feedthroughs must be provided based on memory requirements.

⁽²⁾ Ensure that the USBPHY_PD bit is set to 1 before the 3.3-V power supply (vdda_usba0otg_3p3v) to USB PHY is shut down. If this bit remains at 0 after the 3.3-V power supply is shut down and the 1.8-V supply to USB is on, some leakage might be seen on the 3.3-V supply.

| vdds_1p8_fref | Oscillator, slicer, fref_clk0_out, and fref_clk_ireq |

For more information about power management, see [Section 3.7 Power Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

The OMAP power supply structure is based on the following constraints:

- Because most of the I/Os must be powered before the core, they are supplied on a specific rail (1.2 or 1.8 V).
- MPU, IVA/ABE, and Core are mapped on dedicated SMPS to allow independent SmartReflex dynamic frequency and voltage scaling for each of them.
- Because the DPLL, DSI, CSI, and USB OTG interfaces are noise-sensitive power domains, they are supplied by a dedicated rail to avoid other power sinks from affecting their power rail.
- Because bandgap, BodyBias LDOs, and SRAM LDOs must be supplied at 1.8 V from the beginning of the power-up sequence up to the end of power down, they are supplied by V1V8. This also applies to WKUP LDO at 1.2 V.
- Video DAC, eFuse VPP, SDMMC, and USB I/Os have specific requirements (sequencing, dual voltage, noise immunity, etc.) that require each of them be supplied by a dedicated power source.

27.2.2 Access to Power-Management IC

The ROM code accesses the power-management chip for the following purposes:

- SD/MMC1 powering:
 - The VMMC LDO is switched on by the ROM code when booting from the SD/MMC1 interface.

NOTE: The power supplies required for SD/MMC interface 2 are not controlled by the ROM code. It is assumed that the power-management chip (or the system hardware) properly powers the SD/MMC module attached to this interface.

- USB peripheral booting (internal or external transceiver):
 - PrevStartOk mechanism

This mechanism provides the ability to bypass the USB connection if a specific flag is set in the TWL6030 RTC domain (retained when the system is switched off).

- USB transceiver powering
The TWL6030 VUSB LDO is turned on by the ROM code.

NOTE: If the TWL6030 is not present and the USB external transceiver boot is chosen, the TWL6030-related operations do not complete without blocking the USB boot procedure.

- USB peripheral booting (internal transceiver):
 - VBUS detection
The VBUS power pad is localized on the TWL6030 power IC. As a result, the ROM code must read from a TWL6030 register to get the status reflecting the device attachment to the USB link.
 - Gating the TWL6030 USB charging circuitry during a suspend scenario
If this event occurs, the ROM code should detect a suspend event and gate the charge circuitry inside the TWL6030.

NOTE: If the TWL6030 and/or VBUS are not detected, the USB boot is blocked when booting from the internal transceiver.

27.2.2.1 Power-Management IC Detection

When booting from an SD/MMC card or USB internal transceiver (and only for these two booting options) the ROM code attempts to access the power device through the inter-integrated circuit (I²C™). The first access is a read transaction to obtain the TWL6030 version register. If this read access is successful (that is, the I²C transaction is acknowledged), the ROM code considers that a power-management device is attached, assuming it is TWL6030. The version value read is not used in any computation or compared to any hardcoded value.

If the first read transaction fails (that is, the I²C transaction times out or is not acknowledged), the ROM code logs it into a flag and does not try any further transaction until the next reset cycle. In this case, the nondetection of the companion chip does not block the SD/MMC1 boot process. However, the MMC card boot procedures do not work as defined in this document. In particular, the ROM code does not ensure that the SD/MMC1 interface is powered when accessing the memory contents.

The nondetection of the companion chip blocks the USB internal transceiver boot. The only way to boot from the USB internal transceiver without the TWL6030 is to have the alternate power-management IC match (or emulate) at least read commands P1, P2, and P8 (see [Section 27.2.2.2, Summary of the I²C Transactions](#)). In that case, the following functions are not ensured to work:

- The PrevStartOk mechanism is not functional (the specific flag is not checked).
- The ROM code does not ensure that the VUSB power is applied to the USB transceiver.
- Peripheral booting from the internal USB transceiver is not ensured to be functional, because the VBUS state read transaction is not performed.
- The ROM code does not support the suspend scenario during USB peripheral boot from the internal transceiver.

From the ROM code perspective, nothing prevents the use of another power IC together with the multimedia device. However, special care must be taken if considering the two previously mentioned booting options (SD/MMC1 or USB internal transceiver).

[Table 27-2](#) summarizes the USB booting options according to TWL6030 presence.

Table 27-2. USB Booting Options

| Booting Option | TWL6030 Detected | TWL6030 Emulated | Description |
|----------------|------------------|------------------|-----------------------------------------------------------------------|
| USB | Yes | N/A | Full USB booting |
| USB | No | Yes | ROM code does not guarantee VUSB, VBUS, PrevStartOk, or suspend mode. |
| USB | No | No | USB booting is not possible. |

Table 27-2. USB Booting Options (continued)

| Booting Option | TWL6030 Detected | TWL6030 Emulated | Description |
|----------------|------------------|------------------|----------------------------------------------------------------------------------------------------|
| USB-ULPI | Yes | N/A | ROM code does not guarantee VUSB or VBUS. PrevStartOk is supported. Suspend mode is not supported. |
| USB-ULPI | Yes | Yes | ROM code does not guarantee VUSB, VBUS, or PrevStartOk. Suspend mode is not supported. |
| USB-ULPI | Yes | No | ROM does not guarantee VUSB or VBUS. PrevStartOk and suspend mode are not supported. |

27.2.2.2 Summary of the I²C Transactions

The ROM code accesses the power-management chip through the I2C1 interface. [Table 27-3](#) summarizes the list of accesses.

Table 27-3. Register Accesses to PMIC

| ID | I ² C Address | Register Address | TWL6030 Register | Access Type | Value | Transaction Condition |
|----|--------------------------|------------------|------------------|-------------------------|----------|-------------------------------------|
| P1 | 0x4A | 0x87 | JTAGVERNUM | R | 0x- | Booting from MMC1, USB, or USB-ULPI |
| P2 | 0x48 | 0x2B | PHOENIX_SEQ_CFG | R/W | 0x-/0x00 | Booting from USB or USB-ULPI |
| P3 | 0x48 | 0x9B | VMMC_CFG_VOLTAGE | W (ORed) ⁽¹⁾ | 0x15 | Booting from MMC1 |
| P4 | 0x48 | 0x9A | VMMC_CFG_STATE | W | 0xE1 | Booting from MMC1 |
| P5 | 0x48 | 0xA3 | VUSB_CFG_VOLTAGE | W (ORed) ⁽¹⁾ | 0x18 | Booting from USB or USB-ULPI |
| P6 | 0x48 | 0xE5 | MISC2 | W (ORed) ⁽¹⁾ | 0x08 | Booting from USB or USB-ULPI |
| P7 | 0x48 | 0xA2 | VUSB_CFG_STATE | W | 0xE1 | Booting from USB or USB-ULPI |
| P8 | 0x49 | 0xE3 | CONTROLLER_STAT1 | R | 0x- | Booting from USB or USB-ULPI |
| P9 | 0x49 | 0xE8 | CHARGERUSB_CTRL1 | W | 0x80 | Booting from USB |

⁽¹⁾ The register is not blindly overwritten but is first read and then ORed with the specified value.

Transaction description

P1: JTAGVERNUM: Power-management IC detection. There must be a register at this location; however, its value is not used further by ROM code.

P2: PHOENIX_SEQ_CFG: The PrevStartOk flag is checked when performing USB peripheral boot (internal or external transceiver). If the flag is set, the USB peripheral booting procedure is skipped. In any case the full register is cleared (write 0x00) after the read transaction.

P3: VMMC_CFG_VOLTAGE: For the sake of powering the SDMMC1 card cage, the VMMC_CFG_VOLTAGE and VMMC_CFG_STATE registers are configured to set the VMMC LDO to 3 V. The value 0x15 is written to the VMMC_CFG_VOLTAGE register (selects 3-V output).

P4: VMMC_CFG_STATE: The value 0xE1 is written to the VMMC_CFG_STATE register (applies to all register groups, LDO state switched on).

P5: VUSB_CFG_VOLTAGE: The USB internal transceiver must be powered with a 3.3-V source to ensure its correct functionality. Three registers are used for this purpose. The VUSB_CFG_VOLTAGE register is written the value 0x18 for selecting 3.3 V.

P6: MISC2: The MISC2 register is written the value 0x08 for selecting the VBUS source.

P7: VUSB_CFG_STATE: The VUSB_CFG_STATE register is written the value 0xE1 for switching the VUSB LDO on for all register groups.

P8: CONTROLLER_STAT1: VBUS detection is performed by reading the VBUS_DET bit from the CONTROLLER_STAT1 register. If this bit is set it reflects that a USB cable is plugged.

P9: CHARGERUSB_CTRL1: This register is written the value 0x80 (SUSPEND_BOOT = 1) for gating the charge circuitry when getting a USB SUSPEND event. If this bit is not set, the USB boot is aborted.

The complete description of TWL6030 register map can be found in TWL6030 documentation.

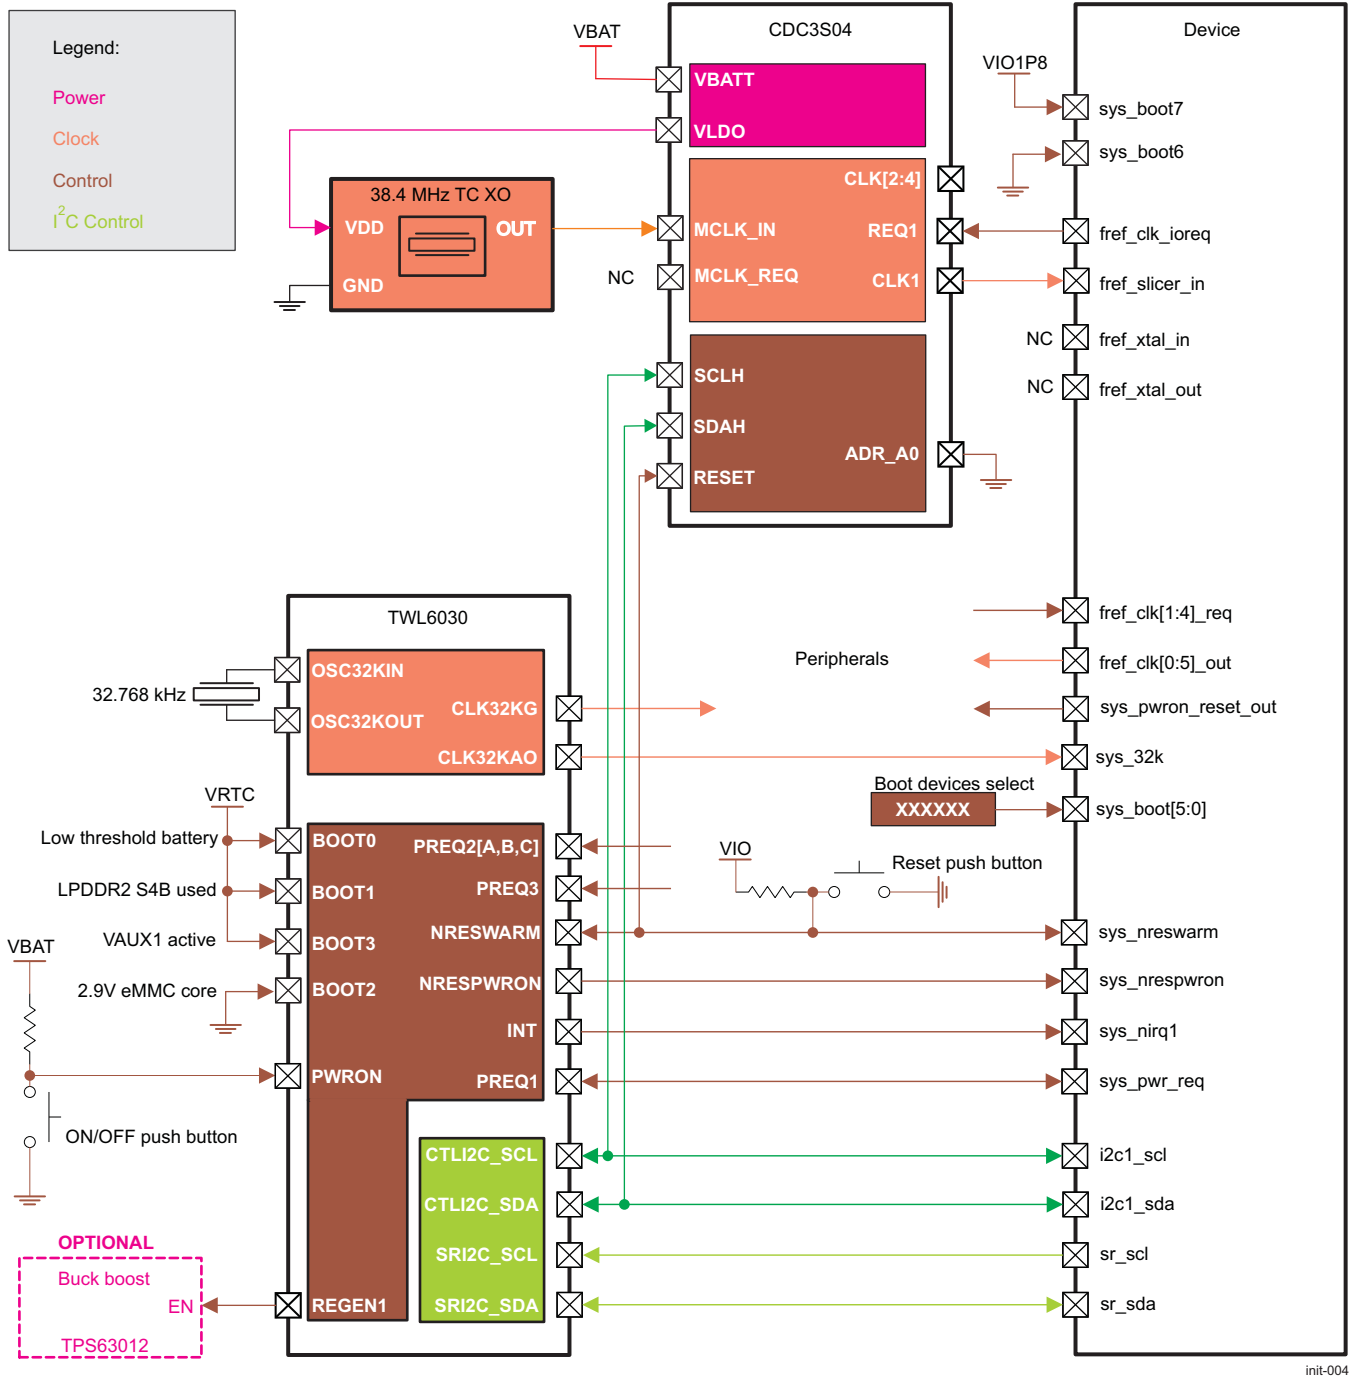

NOTE: No specific action is performed regarding the TWL6030 primary watchdog feature. In particular, if it is active (configurable in EEPROM) in the companion device, a system reset may occur before ROM code completes. The elapse value for the reset must be appropriately tuned so that the ROM code is not interrupted before the full platform start up (that is, before the initial software can take a specific action).

27.2.3 Clock, Reset, and Control

27.2.3.1 Overview

Figure 27-3 shows the clock and reset environment that gathers the clocks and reset-related signals at the system level, and the system-expansion signals.

Figure 27-3. Clock, Reset and Control Environment

The main features of the system interface are:

- A clock request output to an external clock source
- 12-, 16.8-, 19.2-, 26-, or 38.4-MHz reference clock input from external oscillator or clock supplied using

internal crystal oscillator (up to 20 MHz)

- 32-kHz CMOS clock input
- Six configurable output clocks
- Eight input signals to define the boot mode and device system clock source
- Two reset sources
 - Power-on reset (POR) (cold reset)
 - Bidirectional warm reset

27.2.3.2 Clocking Scheme

27.2.3.2.1 Required System Input Clocks

The device operation requires external input clocks, as follows:

- 32k-clock: A 32.768-kHz crystal is connected to the TWL6030 power companion that embeds the 32k oscillator (a square CMOS clock can also be delivered on the 32k_xtalin pin if the 32k crystal is connected on another device of the system). The resulting 32k-clock is delivered to the entire system on three outputs:
 - CLK32KAO_{is} is always on (meaning that when TWL6030 power VIO is on; that is, it is in WAIT-ON or ACTIVE state). It is used to deliver a 32k-clock to always-on features, such as the multimedia device and modem in the described system.
 - CLK32KG is software-controlled and is delivered when requested by the multimedia device (this input is on by default at platform boot).
 - CLK32KAUDIO is software-controlled and is delivered to the TWL6040 audio companion (not shown in [Figure 27-3](#)) when requested by the multimedia device (this input is on by default at platform boot).
- High-speed clock: The platform high-speed (HS) low-jitter sine clock is provided by the clock driver (CDC3S04) to the TWL6040 audio IC, multimedia device, and other peripherals requesting low-jitter sine clock (up to three outputs are available for peripherals). The multimedia device delivers digital clocks to other peripherals. The multimedia device supports different flavors of clock sources at several frequencies:
 - Crystal source. An internal oscillator embedded in the multimedia device is used. In this mode, the input clock is limited to 20 MHz by oscillator construction. The `fref_clk_ioreq` is then set as an input to be used by an external device to request the multimedia device to deliver the clock on `fref_clk0_out`. Pin `fref_slicer_in` can then be used to input an auxiliary clock (mainly for debugging purposes).
 - External oscillator type source. The internal oscillator is disabled. The external source delivers a sine (slicer active) or square (slicer bypassed) single-ended clock on `fref_slicer_in` pin. The external source is enabled by the `fref_clk_ioreq` output. `fref_xtal_in` can then be used to input an auxiliary clock (oscillator-bypass mode).
- Audio clock: The TWL6040 audio companion builds its own clock, either from the 32k clock or the HS clock (depending on the audio scenario). This internal clock is delivered to the ABE subsystem (`abe_clks` input) for audio flow synchronization.

Clock input modes are selected by the `sysboot` pin (`sys_boot[6:7]`) to allow the system to wake up in the proper mode, even after a cold boot (selection of the relevant input pin (`fref_slicer_in` or `fref_xtal_in/out`) and slicer/oscillator mode setting (on or bypass)).

The multimedia device provides the HS clock to other devices through six `fref_clk[0:5]_out` pins.

TWL6040 audio companion receives the HS clock on the MCLK pin when the audio scenario requires it (some low-power audio player scenarios can be performed only with the 32k-clock).

[Table 27-4](#) lists the mapping for the clock input sources. [Table 27-5](#) lists the TWL6030 clock requirements.

Table 27-4. Mapping for Input Sources

| Input Source | Mapping | Frequency Range/List | Type |
|---------------------|----------------------------|---------------------------------|-----------------------------|
| Internal oscillator | fref_xtal_in/fref_xtal_out | 12, 16.8, or 19.2 MHz | Crystal connection balls |
| External HS clock | fref_slicer_in | 12, 16.8, 19.2, 26, or 38.4 MHz | Sine or square single ended |
| External 32k-clock | sys_32k | 32.768 kHz (nom.) | Square |
| TWL6040 audio IC | abe_clks | <19.2 MHz | Square |

Table 27-5. TWL6030 Clock Requirements

| Input Source | Mapping | Frequencies Range/List | Type |
|---------------------|--------------------|------------------------|-------------------------|
| Internal oscillator | OSC32KIN/OSC32KOUT | 32.768 kHz (nom.) | Crystal connection pins |

CAUTION

Clock configurations depend on core voltage, and maximum clock frequencies may not be applicable to production.

27.2.3.2.2 Optional System Output Clocks

The multimedia device can output six alternate clocks, `fref_clk[0:5]_out`. Output clocks 1 through 4 can be gated or enabled through associated clock-request signals, `fref_clk[1:4]_req`.

The clocks can be managed by software with the appropriate register in the power, reset, and clock management (PRCM) module. For more information, see [Section 3.3, PRCM Subsystem Environment](#).

27.2.3.3 Reset Configuration**27.2.3.3.1 ON/OFF Interconnect and Power-On-Reset**

The entire system is typically awakened by an ON/OFF push button connected to the TWL6030 power IC. This signal belongs to the VBAT power domain and is active low (the TWL6030 internal pullup ties it to VBAT). Power up is propagated to the multimedia device through `NRESPWRON/sys_nrespwron` signals when the TWL6030 power-up sequence is achieved. Because this signal is also provided to the TWL6040 audio IC, it resets its state-machine and gets some available functions even if V2V1 power supply is not provided.

27.2.3.3.2 Warm Reset

A warm reset can be asserted by the multimedia device, by an external button (typically for development platform), or by any other device connected to it. It is mainly used to propagate the OMAP4430 internal reset to the whole platform to set it to a known state.

The multimedia device releases `sys_nreswarm` after `NRESPWRON` is deasserted.

27.2.3.3.3 Peripheral Reset by `sys_pwron_reset_out`

`Sys_pwron_reset_out` is provided to the system by the multimedia device to power on and/or deactivate the reset of system peripherals. This signal is activated by `SCRM` during the power-up sequence a few milliseconds after the default-on clocks (OMAP – `fref_clk4_out` and `CDC3S04 – CLK[1:4]`) are stabilized. This allows switching on peripherals that require synchronous reset.

`Sys_pwron_reset_out` is controllable by software when the system is on. It is not affected by a warm reset.

27.2.3.3.4 Peripheral Reset by GPIO

Most of the peripherals are reset/power on/off by GPIO. By default, under POR, most multimedia device signals are in safe mode with a default value driven by the I/O cell. The value is driven by an internal pullup or pulldown. Depending on the peripheral reset active level, users must select one GPIO or another (according to the reset value).

Once POR is released, the value on the pad is driven by the default configuration of control module. Most of time, this configuration is aligned with the default value selected on the I/O cell.

The next step is application-dependent: Users must configure the multimedia device registers to validate GPIO use and the default configuration of the control module.

27.2.3.3.5 Warm Reset Impact on GPIOs

When a warm reset event occurs:

- The GPIO controller is reset. Consequently, the GPIO is automatically turned in input mode.
- The control module is not reset. Information related to signal multiplexing mode and pullup or pulldown configuration is still valid.

Therefore, when a warm reset event happens, the output buffer is disabled. Consequently, to avoid getting a floating signal during (and after) a warm reset event and to keep the same value that was driven before the reset, users must align the pull value with the drive value each time there is an access to a dedicated GPIO register.

NOTE: Failing to align pulls with the buffer driving value (for example, pullup enabled with buffer driving low) will cause unnecessary power consumption.

NOTE:

- For more information about device reset management, see [Section 3.5, Reset Management Functional Description](#).
 - To determine the cause of the last reset, see [Section 3.5.5, Reset Logging](#), in [Chapter 3, Power, Reset, and Clock Management](#).
-

27.2.3.4 TWL Power/Audio Devices Control

- I²C:

The TWL6030 power and TWL6040 audio companions are controlled by the I2C1 (HS I²C). Some internal pullup resistors are provided by the multimedia device (different values can be selected to adapt the I/O buffer strength to the bus topology). The I²C links must first be started in fast-speed mode. Therefore, the buffer default pullup value must support this mode.

- SmartReflex control:

Some of the TWL6030 power resources are controlled through SmartReflex link (I²C-like). This control allows the host to drive the dynamic-frequency voltage scaling (DVFS) and adaptive voltage scaling (AVS) operations of these resources. As with its I²C interfaces, some internal pullup resistors are provided on the SmartReflex I/Os. The link must be run at the highest speed allowed by the voltage controller (lower than I²C HS mode frequency). For example, this frequency must be 1.82 MHz with a 38.4-MHz system clock.

- INT:

Both devices can activate the INT signal at any time when they require the host device to monitor their activity. When receiving such an interruption, the multimedia device checks, through the I²C, to determine the source of the interrupt. These INT pins are active low.

- Sys_pwr_req:

When exiting off mode, the multimedia device ties up the sys_pwr_req pin to wake up the TWL6030 power application group.

27.2.3.5 TWL6030 Power Request Signals

The TWL6030 power-management IC drives three external enable-output signals. This allows switching on some external resources at different stages of the power-up sequence:

- REGEN1/2 are driven high at the beginning of the power-up sequence, before any internal power source is turned on. They belong to the VBAT power domain. REGEN1 can typically be used for buck boost control.
- SYSEN is driven high immediately after the VMEM power output is turned on. It allows switching on an additional regulator in case the VMEM power regulator does not support the current requirements of memory. SYSEN belongs to the VIO power domain.

TWL6030 power also receives five power resource requests: PREQ[1, 2A, 2B, 2C, 3]. These pins allow an external device to request TWL6030 power internal resources. TWL6030 power behavior when pins are activated must be programmed after the first boot (resources and PREQ pins allocated by group, resource behavior upon group activation, etc.). The typical PREQ allocation per group is:

- PREQ1: Application group. Connected to OMAP.
- PREQ2A, PREQ2B, and PREQ2C: Peripheral group. Connected to peripherals A, B, and C (for instance, BT/FM/GPS/WLAN device, Wimax device, W-USB device)
- PREQ3: Modem group

NOTE: Powering the clock driver requires PREQ assertion. Therefore, it is advised to connect any peripheral receiving a clock from CDC3S04 to one PREQ.

The use of PREQ[1:3] is especially required when TWL6030 power is in sleep mode, because it cannot handle an I²C command. Any device that requires the TWL6030 resource to wake up must first activate its associated PREQ. All TWL6030 power regulators are off or in sleep mode when TWL6030 power is in sleep mode.

PREQ1 is used by the multimedia device when waking up from off mode to wake up the TWL6030.

27.2.4 Boot Configuration

Six external pins (sys_boot[5:0]) are used to select interfaces or devices for the booting list. The sys_boot[7:6] pins select the device clock source configuration.

All eight pins are sampled and latched onto the SYCTRL_GENERAL_CORE_CONTROL_STATUS[7:0] SYS_BOOT register bit field after POR. After booting, these pins can be used for other functions such as GPIOs, and the associated register bit field is not updated by the new functionality. See [Section 18.4.8, Pad Functional Multiplexing and Configuration](#), for more information about pad multiplexing configuration.

NOTE:

- If used as GPIOs, sys_boot[7:0] pads must be used only in output mode to ensure that the input values are selected by the pullups and pulldowns after POR.
 - Unlike sys_boot[5:0] pads, sys_boot[7:6] pads have no internal pullups or pulldowns automatically selected at POR. The sys_boot[5:0] pads have selected pulldowns at that moment. To avoid leakage, care must be taken to disable the pulldown in case the respective pad has external connection to VIO (= 1). See the appropriate register fields in *Control Module*.
-

27.2.4.1 System Clock Source Selection

[Figure 27-4](#) is an overview of the system clock selection. [Table 27-6](#) summarizes the selection.

Figure 27-4. System Clock Selection Diagram

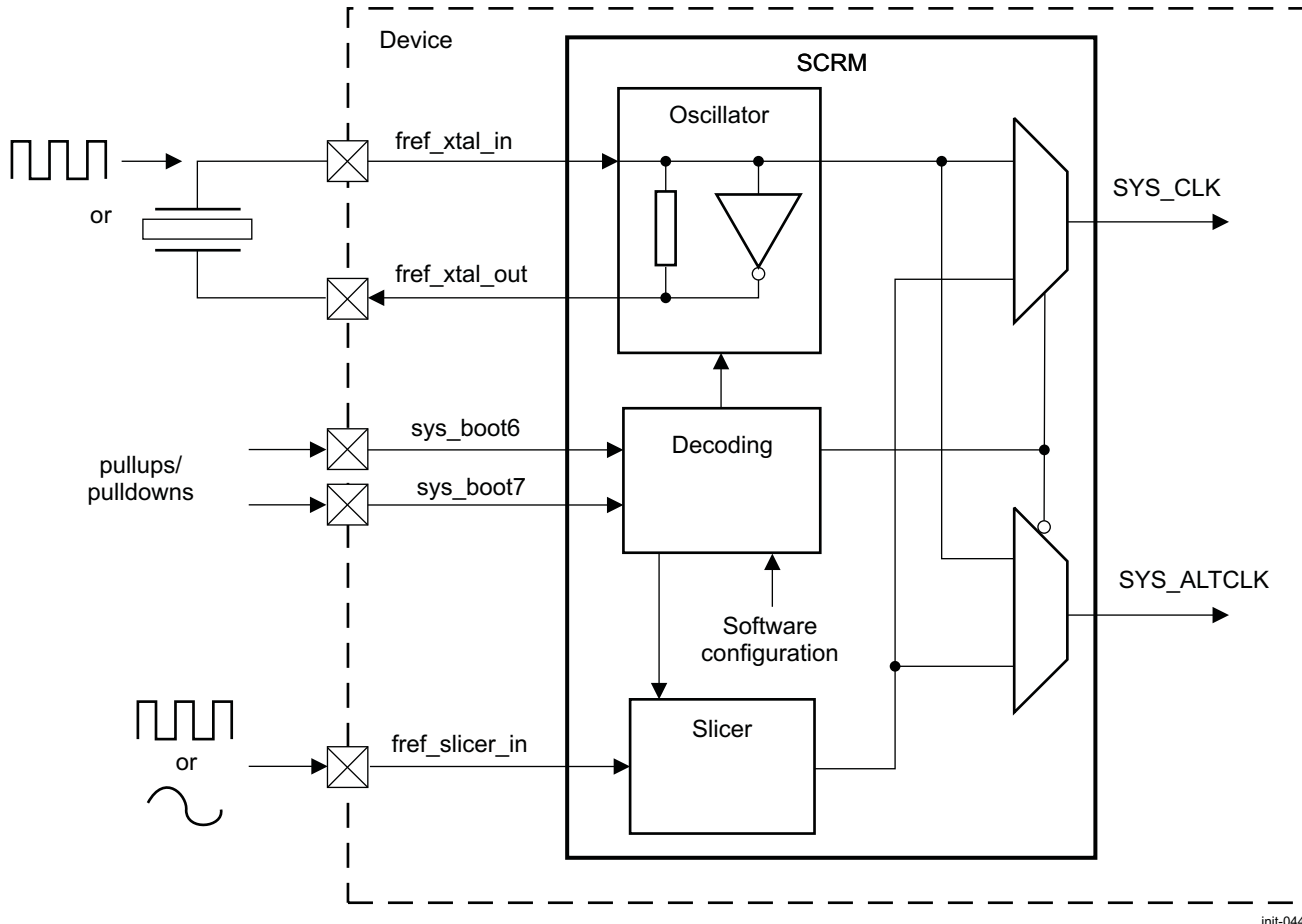

Table 27-6. System Clock Selection Summary

| sys_boot[7:6] | SYS_CLK Source | SYS_ALTCLK Source | Oscillator Mode | Slicer Mode | fref_clk_ioreq Mode |
|---------------|----------------|-------------------|-----------------|-------------|---------------------|
| 0b00 | fref_xtal_in | fref_slicer_in | Active | Power-down | Input |
| 0b01 | fref_xtal_in | fref_slicer_in | Bypass | Power-down | Output |
| 0b10 | fref_slicer_in | fref_xtal_in | Power-down | Active | Output |
| 0b11 | fref_slicer_in | fref_xtal_in | Power-down | Bypass | Output |

System clock source settings description:

- sys_boot[7:6] = 0b00:
 - The system clock source is the on-chip oscillator.
 - The slicer is powered down and its input can be used to provide the multimedia device with an alternate clock.
 - fref_clk_ioreq is a clock request input associated to fref_clk0_out by default.
- sys_boot[7:6] = 0b01:
 - The system clock source is external. The internal oscillator is bypassed to inject the system clock.
 - The slicer is powered down and the slicer input can be used to provide the chip with an alternate clock.
 - The fref_clk_ioreq signal is an output that requests the clock to the external clock supplier
- sys_boot[7:6] = 0b10:

- The system clock source is the on-chip slicer, supplied by an external oscillator. The internal oscillator is powered down and the input can be configured to supply the alternate system clock to multimedia device.
- The slicer is active.
- The `fref_clk_ioreq` signal is an output that requests the clock from the external clock supplier.
- `sys_boot[7:6] = 0b11`:
 - The system clock source is external. The internal oscillator is powered down and the input can be configured to supply the alternate system clock to the multimedia device.
 - The slicer is bypassed to inject the system clock.
 - The `fref_clk_ioreq` signal is an output that requests the clock from the external clock supplier.

27.2.4.2 Booting Device Order Selection

The ROM code creates the device list (order) based on information gathered from two locations.

- The first location is the software booting configuration stored in the nonvolatile save-and-restore (SAR) memory, and used after warm resets.
- The second location is the `sys_boot[5:0]` external configuration pins sensed in the control module. The SYSBOOT pins are used to index a booting device list from a table with possible booting scenarios. The order of examined booting devices is from the first to the fourth devices.

The following names are used in the tables:

- Memory types:
 - Execute in place (XIP): XIP memory without wait-signal monitoring enabled (NOR flash memory or other XIP device)
 - XIP wait: XIP memory with wait-signal monitoring
 - NAND: NAND flash memories (non-XIP)
 - OneNAND: OneNAND and Flex-OneNAND flash memories
 - EMIF: LPDDR2-NVM device
 - MMC1: MMC/SD card or eMMC/eSD™ device (SD/MMC port 1)
 - MMC2(1): eMMC or eSD memory device, first option (SD/MMC port 2). See [Section 27.2.4.3, Boot Peripheral Pin Multiplexing](#).
 - MMC2(2): eMMC or eSD memory device, second option (SD/MMC port 2). See [Section 27.2.4.3, Boot Peripheral Pin Multiplexing](#).
- Peripheral interfaces:
 - USB: USBA0 from internal transceiver (USBPHY)
 - USB-ULPI: USBA0 from external transceiver through ULPI interface
 - Universal asynchronous receiver/transmitter (UART): UART3 interface
- Permanent booting devices listed in [Table 27-7](#) are in **bold**.

NOTE: Only permanent booting devices (in bold) are put on in the list in case of a warm reset, and the device list is taken from the `sys_boot` pins. As a result, peripheral booting devices are skipped when the multimedia device restarts from warm resets.

Users can force the execution of the peripheral booting procedure after warm reset by using the software booting configuration feature.

[Table 27-7](#) lists the booting device order when it is preferred to boot from a memory type device. This table is selected by ROM code when `sys_boot5` pin is tied high (= 1) after reset and before booting completion. If fast XIP booting is selected, the `sys_boot5` pin controls the XIP wait-signal monitoring (that is, a logical high level enables wait-signal monitoring).

Table 27-7. Memory Preferred Booting

| sys_boot[5:0] | Booting Devices Order | | | |
|-------------------------|---------------------------------------------|-----------------|-----------------|-----------------|
| | 1 st | 2 nd | 3 rd | 4 th |
| 0b100000 | MMC2(1) | USB | | |
| 0b100001 | XIP | USB | | |
| 0b100010 | XIPWAIT | USB | | |
| 0b100011 | NAND | USB | | |
| 0b100100 | EMIF | USB | | |
| 0b100101 | MMC1 | USB | | |
| 0b100110 | OneNAND | USB | | |
| 0b100111 | OneNAND | MMC2(1) | USB | |
| 0b101000 | MMC2(1) | UART | | |
| 0b101001 | XIP | UART | | |
| 0b101010 | XIPWAIT | UART | | |
| 0b101011 | NAND | UART | | |
| 0b101100 | EMIF | UART | | |
| 0b101101 | MMC1 | UART | | |
| 0b101110 | OneNAND | UART | | |
| 0b101111 | MMC2(1) | USB-ULPI | | |
| 0b110000 | XIP | USB-ULPI | | |
| 0b110001 | XIPWAIT | USB-ULPI | | |
| 0b110010 | NAND | USB-ULPI | | |
| 0b110011 | EMIF | USB-ULPI | | |
| 0b110100 | MMC1 | USB-ULPI | | |
| 0b110101 | OneNAND | USB-ULPI | | |
| 0b110110 | MMC2(1) | USB | UART | MMC1 |
| 0b110111 | XIP | USB | UART | MMC1 |
| 0b111000 | MMC2(2) | USB-ULPI | UART | |
| 0b111001 | NAND | USB | UART | MMC1 |
| 0b111010 | MMC2(2) | UART | | |
| 0b111011 | MMC1 | USB | UART | |
| 0b111100 | MMC2(2) | USB | | |
| 0b111101 | | | Reserved | |
| 0b111110 | | | Reserved | |
| 0b111111 ⁽¹⁾ | Fast XIP booting. Wait monitoring ON | | USB | UART |

⁽¹⁾ Only on GP devices

Table 27-8 lists the booting device order when it is preferred to boot from a peripheral-type device. This table is selected by ROM code when the sys_boot5 pin is tied low (= 0). If fast XIP booting is selected, the sys_boot5 pin controls the XIP wait-signal monitoring (that is, a logical low level disables wait-signal monitoring).

Table 27-8. Peripheral Preferred Booting

| sys_boot[5:0] | Booting Devices Order | | | |
|-------------------------|---------------------------------------|-----------------|-----------------|-----------------|
| | 1 st | 2 nd | 3 rd | 4 th |
| 0b000000 | USB | MMC2(1) | | |
| 0b000001 | USB | XIP | | |
| 0b000010 | USB | XIPWAIT | | |
| 0b000011 | USB | NAND | | |
| 0b000100 | USB | EMIF | | |
| 0b000101 | USB | MMC1 | | |
| 0b000110 | USB | OneNAND | | |

27.2.4.3 Boot Peripheral Pin Multiplexing

Table 27-9 lists the code pin multiplexing configuration supported by ROM according to boot peripheral.

Table 27-9. Pin Multiplexing According to Boot Peripheral

| Boot Device | Boot Interface | Pins |
|-----------------|----------------------------------------|----------------------------------------------------------------------|
| NAND/OneNAND | GPMC | GPMC pins in mux mode 0, CS0, WAIT0 |
| XIP memory | GPMC | GPMC pins in mux mode 0, CS0, WAIT0 |
| MMC/SD/eMMC/eSD | SDMMC1 | SDMMC1 pins in mux mode 0 |
| eMMC/eSD | SDMMC2 (option 1) SDMMC2 (option 2) | GPMC pins in mux mode 1 SDMMC5 + FREF_CLK pins, all in mux mode 5 |
| LPDDR2-NVM | EMIF1 | LPDDR21 pins in mux mode 0, CS1 |

Table 27-9. Pin Multiplexing According to Boot Peripheral (continued)

| Boot Device | Boot Interface | Pins |
|-------------------------------|-------------------------|----------------------------------|
| UART | UART3 | UART3 pins in mux mode 0 |
| USB from internal transceiver | HSUSBOTG (USBA0-USBPHY) | USBA0_OTG pins in mux mode 0 |
| USB from external transceiver | HSUSBOTG (USBA0-ULPI) | DPM_EMU[2:13] pins in mux mode 1 |

NOTE: The ROM code examines the interfaces that are selected to be searched until a valid bootable interface/device is found. The activities on the pins of the failed interfaces must be considered in case they are connected to any other peripherals for any other purposes (for example, an LED connected to a GPMC pin muxed internally to a GPIO).

27.3 Reset Sequences

For the description of the reset sequences, see [Section 3.5.6, Reset Sequences](#), in [Section 3.5, Reset Management Functional Description](#).

27.4 Device Initialization by ROM Code

This section describes high-level booting concepts and provides basic knowledge for booting on the device.

27.4.1 Booting Overview

27.4.1.1 Booting Types

Booting is the process of starting a bootstrap from one of the booting devices.

The ROM code has two functions for booting: Peripheral booting and memory booting.

- In peripheral booting, the ROM code polls a selected communication interface such as UART or USB, downloads the executable code over the interface, and executes it in internal RAM. Downloaded software from an external host can be used to program flash memories connected to the device. This special case of peripheral booting is called preflashing; software downloaded for preflashing is called the flash loader. The flash loader burns a new client application image in external flash memory. Initial software is a generic term for bootstrap, downloaded software, and flash loader. After the image is burnt, a software (warm) reset can be performed.
- In memory booting, the ROM code finds the bootstrap in permanent memories such as flash memory or memory cards and executes it. This process is normally performed after a cold or warm device reset.

The ROM code detects whether the device should download software from a peripheral interface (USB or UART) by using the `sys_boot[5:0]` pin configuration. This mechanism encompasses initial flashing in production (external memory is empty) and reflashing in service (external memory is already programmed).

27.4.1.2 ROM Code Architecture

Figure 27-5 shows the ROM code architecture. It is split into three main layers with a top-down approach: high-level, drivers, and hardware abstraction layer (HAL). One layer communicates with a lower-level layer through a unified interface.

- The high-level layer performs the main tasks of the public ROM code: multicore startup, watchdog and clock configurations, interrupt management, interaction with the power-management IC, and main booting routine.
- The driver layer implements the logical and communication protocols for any booting device in accordance with the interface specification.
- The HAL implements the lowest level code for interacting with the hardware infrastructure IPs. End booting devices are attached to the device I/O pads.

Figure 27-5 shows the three layers with their modules.

Figure 27-5. ROM Code Architecture

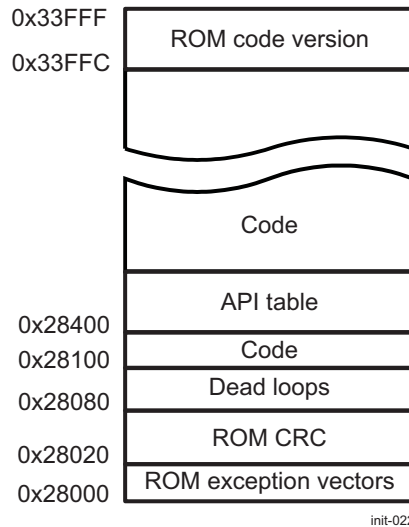

init-006

27.4.2 Memory Maps

27.4.2.1 ROM Memory Map

Figure 27-6 shows the 48-KB ROM memory map.

Figure 27-6. ROM Memory Map

- **ROM exception vectors**
Exceptions are redirected to ROM exception vectors (see [Table 27-10](#)). The reset exception is redirected to the public ROM code startup. Other exceptions are redirected to RAM handlers by loading appropriate addresses to the PC register.

Table 27-10. ROM Exception Vectors

| Address | Exception | Content |
|---------|--------------------------|--------------------------------|
| 0x28000 | Reset | Branch to the ROM code startup |
| 0x28004 | Undefined | PC = 0x4030 D004 |
| 0x28008 | Software interrupt (SWI) | PC = 0x4030 D008 |
| 0x2800C | Prefetch abort | PC = 0x4030 D00C |
| 0x28010 | Data abort | PC = 0x4030 D010 |
| 0x28014 | Unused | PC = 0x4030 D014 |
| 0x28018 | IRQ | PC = 0x4030 D018 |
| 0x2801C | FIQ | PC = 0x4030 D01C |

- **ROM code cyclic redundancy check (CRC)**
The ROM code CRC is calculated as 32-bit CRC code (CRC-32-IEEE 802.3) for the address range 0x28000 - 0x33FFF. The 4-byte CRC code is stored at location 0x28020.
- **Dead loops**
Dead loops are branch instructions coded in ARM™ mode. They have multiple purposes (see [Table 27-11](#)).

Table 27-11. Dead Loops

| Address | Purpose |
|---------|------------------------------------------|
| 0x28080 | Undefined exception default handler |
| 0x28084 | SWI exception default handler |
| 0x28088 | Prefetch abort exception default handler |
| 0x2808C | Data abort exception default handler |
| 0x28090 | Unused exception default handler |
| 0x28094 | IRQ exception default handler |
| 0x28098 | FIQ exception default handler |

The fixed location of these dead loops facilitates debugging and testing. The first seven dead loops are default exception handlers linked to RAM exception vectors.

Dead loops can be called directly from code, but there is also a special function called from ROM code to execute a dead loop. This function is at address 0x280C0. The function is assembly code in ARM mode, which takes the dead loop address from the R0 register. The main purpose of the function is to issue a global software reset before going to a dead loop. In addition, the function clears the global cold reset status before issuing the global software reset.

- Code

This space is used to hold code and constant data.

- API table

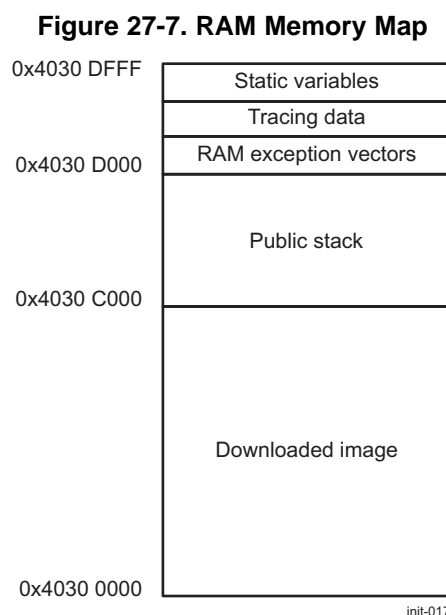

The purpose of this table is to allow external code access to system maintenance, utility, and device driver functions which are used for ensuring the ROM code boot functionality. These functions can be reused at run time by calling a fixed address hardcoded in this table.

- ROM code version

The ROM code version consists of two decimal numbers: major and minor. It can be used to identify the ROM code release version burnt in a given IC (for example, useful during a debugging session). The ROM code version is a 32-bit hexadecimal value located at address 0x33FFC.

27.4.2.2 RAM Memory Map

The partitioning of the on-chip SRAM (L3 OCM RAM) shown in [Figure 27-7](#) is used during the booting process. Tracing and static variables areas can also be accessed when calling API functions.

- Downloaded image

This space is used by the public ROM code to store a downloaded booting image. It can be up to

48KB.

- Public stack
This space is reserved for stack.
- RAM exception vectors

The RAM exception vectors provide an easy way to redirect exceptions to the custom handler. [Table 27-12](#) lists the contents of the RAM space reserved for RAM vectors. The first eight addresses are ARM instructions that load the value in the subsequent eight addresses into the PC. These instructions are executed when an exception occurs because they are called from ROM exception vectors. Undefined, SWI, unused, and FIQ exceptions are redirected to a hardcoded dead loop. Prefetch abort, data abort, and IRQ exception are redirected to predefined ROM handlers. Users can redirect an exception to another handler by writing its address to the appropriate location from 0x4030 D024 to 0x4030 D03C, or by overriding the branch (load into PC) instruction between addresses from 0x4030 D004 to 0x4030 D01C.

Table 27-12. RAM Exception Vectors

| Address | Exception | Content |
|-------------|------------------------------|----------------------------------------------------------|
| 0x4030 D000 | Reserved | Reserved |
| 0x4030 D004 | Undefined | PC = [0x4030D024] |
| 0x4030 D008 | SWI | PC = [0x4030D028] |
| 0x4030 D00C | Prefetch abort | PC = [0x4030D02C] |
| 0x4030 D010 | Data abort | PC = [0x4030D030] |
| 0x4030 D014 | Unused | PC = [0x4030D034] |
| 0x4030 D018 | Interrupt request (IRQ) | PC = [0x4030D038] |
| 0x4030 D01C | Fast interrupt request (FIQ) | PC = [0x4030D03C] |
| 0x4030 D020 | Reserved | 0x28090 |
| 0x4030 D024 | Undefined | 0x28080 |
| 0x4030 D028 | SWI | 0x28084 |
| 0x4030 D02C | Prefetch abort | Address of default prefetch abort handler ⁽¹⁾ |
| 0x4030 D030 | Data abort | Address of default data abort handler ⁽¹⁾ |
| 0x4030 D034 | Unused | 0x28090 |
| 0x4030 D038 | IRQ | Address of default IRQ handler |
| 0x4030 D03C | FIQ | 0x28098 |

⁽¹⁾ The default handlers for prefetch and data abort perform reads from CP15 debug registers to retrieve the reason for the abort:

- In case of prefetch abort: the IFAR register is read from CP15 and stored into R0. The IFSR register is read and stored into the R1 register. Then the ROM code jumps to the prefetch abort dead loop (20088h).
- In case of data abort: the DFAR register is read from CP15 and stored into R0. The DFSR register is read and stored into the R1 register. Then the ROM code jumps to the data abort dead loop (2008Ch).

- Tracing data
This area contains trace vectors reflecting the execution path of the ROM Code. The public ROM code tracing data is described in [Table 27-13](#). For more information about ROM code tracing, see [Section 27.4.9, Tracing](#).

Table 27-13. Tracing Data

| Address | Size (Bytes) | Description |
|-------------|--------------|---------------------------------------|
| 0x4030 D040 | 4 | Current tracing vector, word 1 |
| 0x4030 D044 | 4 | Current tracing vector, word 2 |
| 0x4030 D048 | 4 | Current tracing vector, word 3 |
| 0x4030 D04C | 4 | Cold reset run tracing vector, word 1 |
| 0x4030 D050 | 4 | Cold reset run tracing vector, word 2 |
| 0x4030 D054 | 4 | Cold reset run tracing vector, word 3 |

Table 27-13. Tracing Data (continued)

| Address | Size (Bytes) | Description |
|-------------|--------------|--------------------------------------------------------|
| 0x4030 D058 | 4 | Current copy of the PRM_RSTST register (reset reasons) |
| 0x4030 D05C | 4 | Reserved |
| 0x4030 D060 | 4 | Reserved |
| 0x4030 D064 | 4 | Reserved |

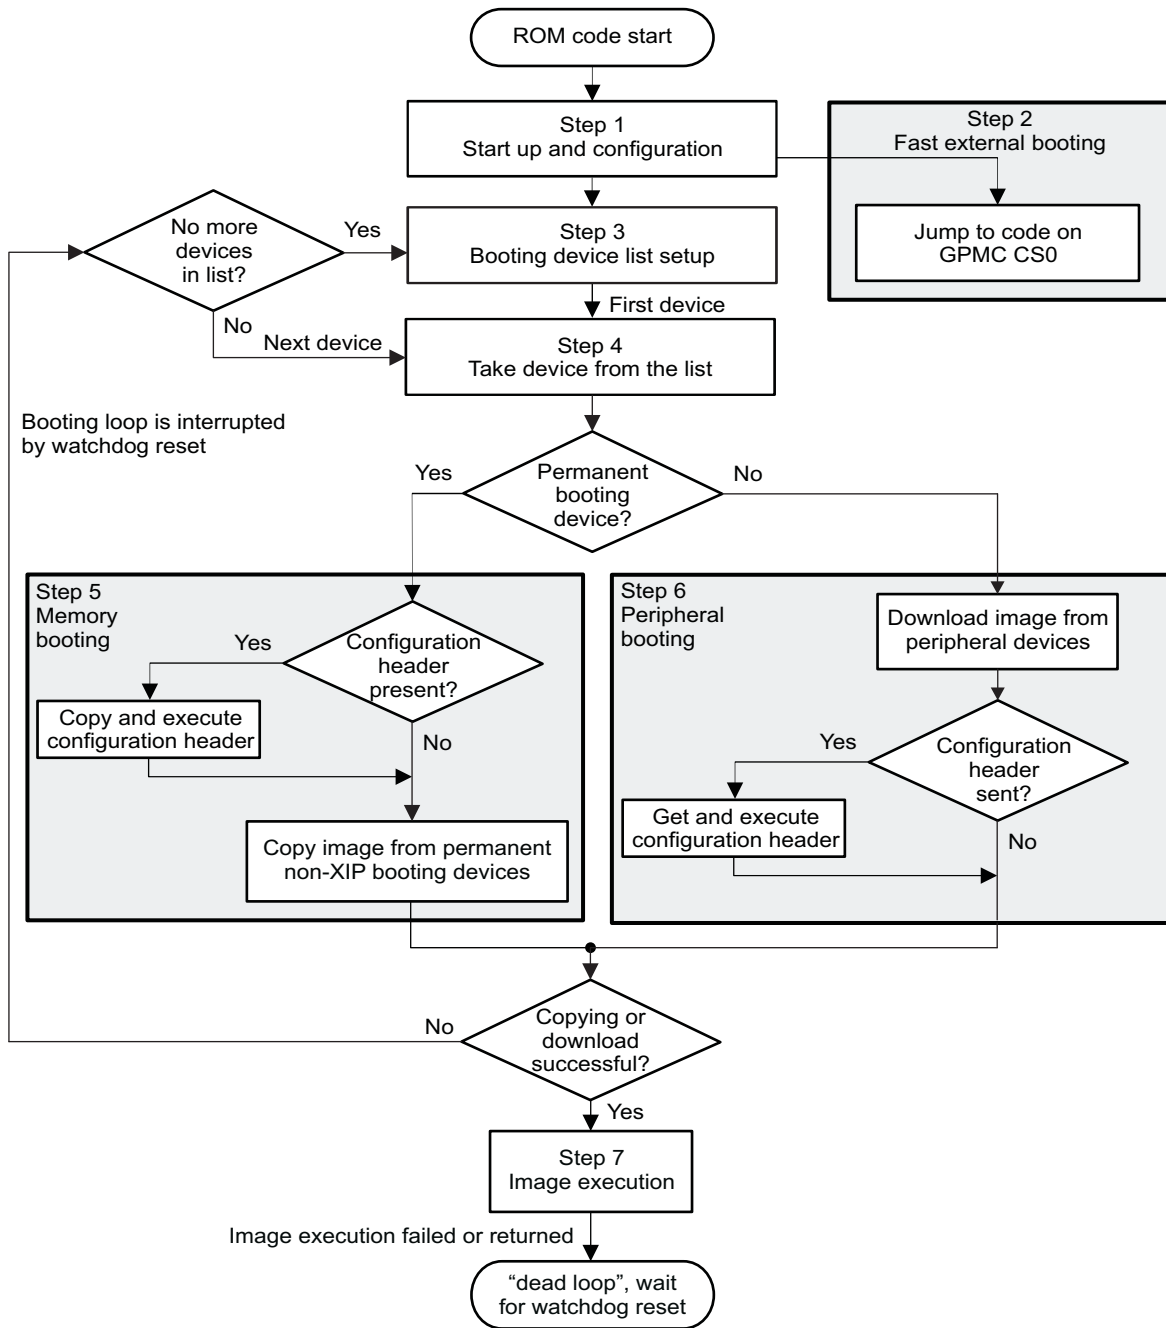

- Static variables

ROM code static variables used at boot time (and possibly during run time if calling the ROM API functions).

27.4.3 Overall Booting Sequence

[Figure 27-8](#) shows the ROM code flow chart.

Figure 27-8. Overall Booting Sequence

init-007

The main loop of the booting module goes through the booting device list and tries to get an image from the currently selected booting device. The ROM code performs the following steps:

- Step 1. Basic configuration and initialization. Reading of SYSBOOT pins or software booting configuration
- Step 2. The path named fast external boot is a special low-latency boot mode. It consists of a blind jump to an external addressable memory. See [Section 27.4.6, Fast External Booting](#).
- Step 3. A booting device list is created (see [Section 27.4.4.3, Booting Device List Setup](#)). The list consists of all devices to be searched for a booting image. The list is created based on the sys_boot pins or the software booting configuration described in [Section 27.4.4.4, Software Booting Configuration](#). The software booting configuration structure is in the SAR memory and can be written by software before executing a software reset. After a software reset, the software booting configuration has priority over the sys_boot pin configuration.
- Step 4. The main loop of the booting procedure goes through the booting device list and tries to search for an image from the currently selected booting device. This loop is exited if a valid booting image is found and successfully executed or upon watchdog expiration. If an image is found, ROM code executes memory booting or peripheral booting, depending on the current booting device type:
 - Memory booting is executed when the booting device is XIP memory, NAND, OneNAND/Flex-OneNAND, LPDDR2-NVM, or eMMC/eSD/MMC/SD.
 - Peripheral booting is executed when the device is a UART or USB.
- Step 5. Memory booting reads data from memory type devices. Memory booting is described in detail in [Section 27.4.7, Memory Booting](#).
- Step 6. Peripheral booting downloads data from communication interfaces. Peripheral booting is described in [Section 27.4.5, Peripheral Booting](#).
- Step 7. For the GP device, the image is automatically started.

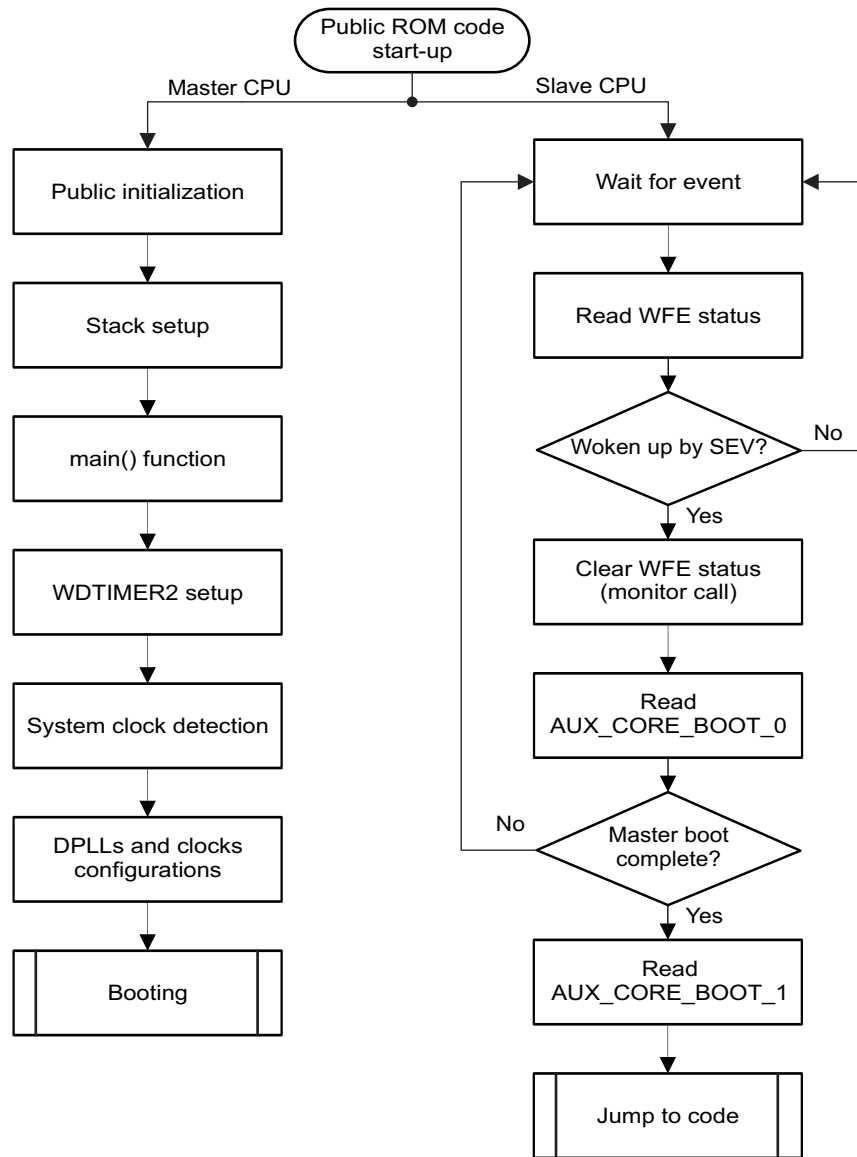

An additional feature of the booting module is the execution of the configuration header (CH). The CH configures the system for faster and more flexible booting from the selected permanent device. The CH, which is optional, is described in [Section 27.4.8.2, Configuration Header](#).

27.4.4 Startup and Configuration

27.4.4.1 Startup

[Figure 27-9](#) shows the ROM code start-up sequence.

Figure 27-9. ROM Code Multiprocessor Start-Up Sequence

init-042

The master CPU L1 instruction cache and branch prediction mechanisms are activated as part of the public boot process. The public vector base address is configured to the reset vector of ROM code (0x28000). The MMU remains switched off during boot (thus, L1 data cache is off). The master CPU performs the public-side basic initialization and stack setup (compiler auto-generated C- initialization or *scatter loading*). Next, it configures watchdog timer 2 (set to 3 minutes), performs system clock detection, and configures the system clock. Finally, it jumps to the booting routine.

No specific configuration is performed for the slave CPU, which keeps its default configuration after reset (L1 instruction and data caches off, branch prediction off, MMU off, no remap of public-vector-base address). The slave CPU is rapidly held in wait-for-event state. It stays in this state while the master CPU completes the public boot process and until jumping to the external software (for example, HLOS). At this stage, the external software can wake up the slave CPU by executing an SEV command.

Two internal memory-mapped registers are available to the OS for communicating start-up information. The AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 registers are located in the MPU WakeupGen domain.

- AUX_CORE_BOOT_0 Is used as a status register to signal the slave CPU that it must wake up after the send event operation initiated by the master CPU.

- The AUX_CORE_BOOT_1 register contains the address location to which the slave CPU must jump after wakeup.
- See the memory mapping of these registers in [Chapter 4, Dual Cortex-A9 Subsystem](#).

27.4.4.2 Clocking Configuration

The ROM code detects the system input clock frequency. The supported frequencies are:

- 12 MHz
- 16.8 MHz
- 19.2 MHz
- 26 MHz
- 38.4 MHz

After detecting the input clock, the ROM code configures the clocks and DPLLs required for ROM code execution.

The configured DPLLs are:

- Peripheral DPLL: Set to provide 192, 128, 96, 48, 24, and 12 MHz for peripheral blocks
- Core DPLL: Set to provide L3/L4 interconnect and MPU and EMIF clocks
- MPU DPLL: Left in bypass, and the MPU internal clock is derived from the core DPLL
- USB DPLL: Locked only in case of USB peripheral booting from internal transceiver. It is left unused in other cases (for example, memory boot or peripheral boot from UART or USB ULPI) to save power.

The multipliers and dividers of the DPLLs are set to values that depend on the input clock detected.

[Table 27-14](#) summarizes the ROM code default settings for key clocks.

Table 27-14. ROM Code Default Clock Settings

| Clock | Frequency [MHz] | Source |
|---------------------------------|-----------------|----------------------|
| FCORE_DPLL | 400 | Derived from SYS_CLK |
| CORE_X2_CLK | 200 | |
| CORE_CLK | 200 | CORE_X2_CLK/1 |
| L3_ICLK | 100 | CORE_CLK/2 |
| L4_ICLK | 50 | L3_ICLK/2 |
| FPER_DPLL | 384 | Derived from SYS_CLK |
| FUNC_192M_CLK | 192 | |
| FUNC_128M_CLK | 128 | |
| FUNC_96M_FCLK | 96 | |
| FUNC_48M_FCLK | 48 | |
| FMPU_DPLL (in bypass) | 200 | CORE_X2_CLK |
| MPU_DPLL_CLK | 200 | FMPU_DPLL/1 |
| FUSB_DPLL ⁽¹⁾ | 960 | Derived from SYS_CLK |
| INIT_960M | 960 | FUSB_DPLL/1 |
| INIT_480M | 480 | INIT_960M/2 |
| INIT_60M | 60 | INIT_480M/8 |

⁽¹⁾ Locked only in case of USB peripheral booting from internal PHY

There are three ways to change DPLLs and all related clock divider, gating, and multiplexer configurations during the boot:

- ROM code default settings, described in this paragraph. They are always applied at any reset. [Table 27-14](#)
- Software booting configuration after a software reset, described in [Section 27.4.4.4, Software Booting Configuration](#)
- Configuration header (CH), described in [Section 27.4.8.2, Configuration Header](#). The CH lets users

have a known configuration (about GPMC and clock registers) after memory booting. This configuration can be blocked by the software booting configuration.

27.4.4.3 Booting Device List Setup

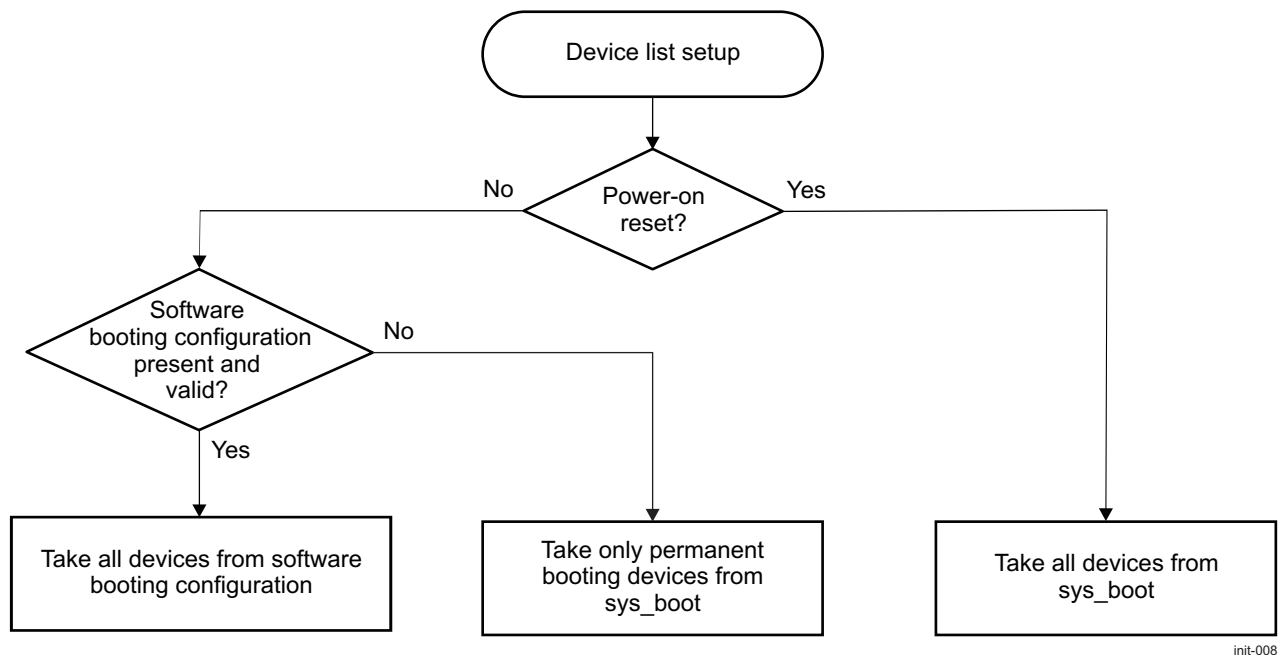

The ROM code creates a device list based on two sources:

- The software booting configuration is stored in nonvolatile RAM SAR memory.
- The sys_boot[5:0] pins sensed in the control module are used to index the device table from which the list of devices is extracted.

Figure 27-10 shows how the ROM code sets up the device list depending on the reset source.

NOTE: Only permanent booting devices are put on the list when reset is not power on and devices are taken from the sys_boot pins. Users can force peripheral booting after software reset using the software booting configuration.

Figure 27-10. Device List Setup

init-008

27.4.4.4 Software Booting Configuration

The software booting configuration is a logical structure stored in SAR RAM memory, which is not cleared after warm resets or wakeups from low-power modes.

27.4.4.4.1 Public Use of SAR RAM

At system level, the SAR RAM memory is divided into four banks. The public ROM code uses only the first bank, which is always public-accessible. More specifically, the software booting configuration structure must be located in the upper 1.5KB of the first bank.

The public ROM code offers some flexibility about the location of the software booting configuration structure. The PUBLIC_SW_BOOT_CFG_ADDR pointer defines the start address of the structure within the SAR RAM bank (see Table 27-15).

Table 27-15. Public Use of SAR RAM

| Logical name | Address | Size (Bytes) | Description |
|-------------------------|------------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PUBLIC_SW_BOOT_CFG_ADDR | 0x4A326A00 | 4 | Public software booting configuration pointer. The word value at this location is: - Reset (zero) on a cold reset. - Read on a warm reset. |
| CPU0_WAKEUP_NS_PA_ADDR | 0x4A326A04 | 4 | CPU0 nonsecure wake-up restoration pointer ⁽¹⁾ |
| CPU1_WAKEUP_NS_PA_ADDR | 0x4A326A08 | 4 | CPU1 Nonsecure wake-up restoration pointer ⁽¹⁾ |
| PUBLIC_SAR_RAM_1_FREE | 0x4A326A0C | ... | Recommended address for start of software booting configuration structure described in Section 27.4.4.4.2, Software Booting Configuration Structure . |

⁽¹⁾ This pointer is used as part of the restoration procedure from low-power modes.

As mentioned previously, the software booting configuration feature is optional. Hence, the public ROM code decides to use the feature based on the value read on a warm reset at the address pointed to by the PUBLIC_SW_BOOT_CFG_ADDR pointer. If the value matches the range 0x4A326A00 – 0x4A326FFF, the ROM code tries to extract the structure located at that address. The value pointed to by PUBLIC_SW_BOOT_CFG_ADDR is always overwritten to zero on a cold reset.

The recommended address for storing the software booting configuration structure described hereafter is defined as PUBLIC_SAR_RAM_1_FREE. It is, however, possible to locate the structure at any location within the 1.5-KB range.

It is moreover possible to use the public SAR RAM area for any other purpose, such as storing traces for HLOS use. Obviously, care must be taken not to overwrite the locations used for low-power modes and/or software booting configuration if used.

27.4.4.4.2 Software Booting Configuration Structure

[Table 27-16](#) describes the software booting configuration structure. It offers three levels of flexibility for redefining the ROM code defaults after a warm reset:

- Redefining the default device booting list (from ROM code defaults given by SYSBOOT pins configuration)
- Redefining the default clock settings
- Redefining timeouts linked to the peripheral booting mechanism

NOTE: The sections are provided as a linked list; therefore, the order and number of items is not relevant.

The ROM code searches for the next section at the location based on the size filled in the previous section. The clock configuration from software booting configuration overwrites the CH settings.

Table 27-16. Software Booting Configuration Structure

27.4.5 Peripheral Booting

27.4.5.1 Description

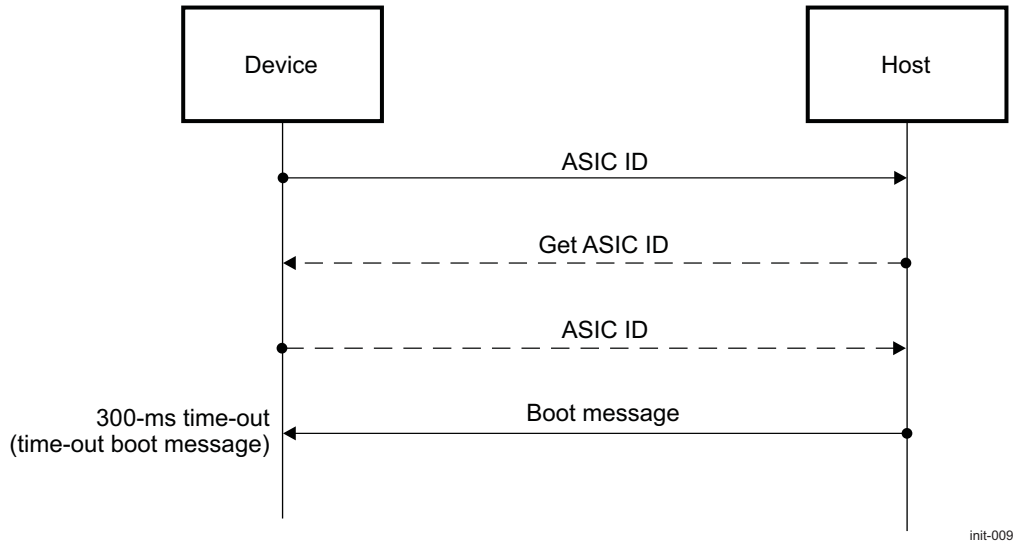

The ROM code can boot from two different peripherals:

- USB: High/full speed USB from internal or external transceiver
- UART3: 115.2 Kbps, 8 bits, even parity, 1 stop-bit

The purpose of booting from a peripheral is to download a flash loader code from an external host. This booting method is used primarily for programming flash memories connected to the OMAP device (for example, in the case of initial flashing, firmware update or servicing). The overall peripheral booting procedure is shown in [Figure 27-13](#). It consists of a synchronization phase (handshake between host and OMAP device) and a transfer phase. The synchronization phase is similar for UART and USB boots. Both transfer phases use the same procedure.

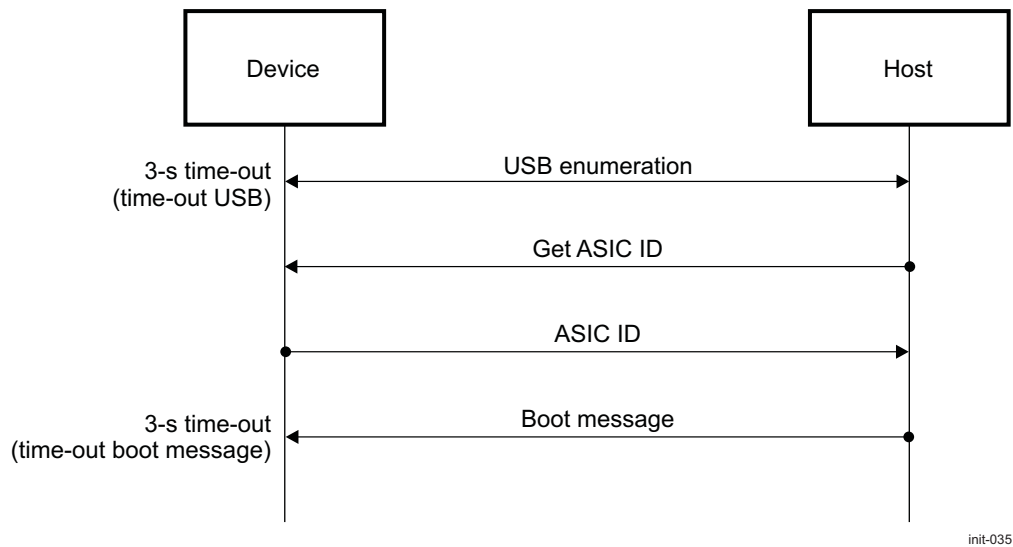

When booting from the UART, the ROM code first initializes the UART3 interface. Then the ROM code sends an ASIC ID block of data. From there, it expects to receive a boot message from the host within 300 ms, by default. [Figure 27-11](#) shows this procedure.

Figure 27-11. Synchronization Phase for UART

[Figure 27-12](#) shows the procedure when booting from the USB.

Figure 27-12. Synchronization Phase for USB

During the synchronization phase ([Figure 27-11](#) and [Figure 27-12](#)), the OMAP device can provide a small packet of data called the ASIC ID (described in [Table 27-17](#)). It is a simple structure that contains different kinds of information, such as ROM version, checksums, and ID.

The default time-outs involved during the synchronization phase can be redefined after a warm reset by means of the software booting configuration (described in [Section 27.4.4.4, Software Booting Configuration](#)). The host can decide the desired operation by providing a booting message ([Table 27-21](#)). This message can be: Get ASIC ID, peripheral boot, change device, or next device. If the OMAP device receives the Get ASIC ID boot message, it sends back the ASIC ID contents.

If the change device or next device message is received, the ROM code stops the current peripheral booting procedure and returns to the main booting, which decides about the next booting device according to the boot message received.

If the peripheral boot message is received without a time-out, the OMAP device is entering the transfer phase. From there, the flash loader image size (as a 32-bit word) and the flash loader image itself are expected to be received. The ROM code waits up to 1 minute for completion of image size reception, and up to 1 more minute to download the image. If the download procedure does not complete before this time, the peripheral booting returns with a TIMEOUT status. ROM code continues to examine the devices included in the booting device list. If the download procedure passes, the peripheral booting returns with a SUCCESS status and the image can be executed.

The USB or UART connection is left open at the end of the transfer phase and once exiting the ROM code for the initial software to take over. It means the initial software can “reuse” the currently established connection. In case of USB, the endpoints can be reused as such, without closing the connection and performing a full enumeration again.

Table 27-17. ASIC ID Structure

| ASIC ID Item | Size (Bytes) | Description |
|-------------------|--------------|---------------------------------------------------------------------------------------------|
| Items | 1 | Number of subblocks |
| ID subblock | 7 | Device identification information |
| Reserved subblock | 4 | This subblock is transmitted, but does not contain useful information in case of GP-device. |
| Reserved subblock | 23 | This subblock is transmitted, but does not contain useful information in case of GP-device. |
| Reserved subblock | 35 | This subblock is transmitted, but does not contain useful information in case of GP-device. |
| Checksum subblock | 11 | CRC (4 bytes) |

Table 27-18. Items

| Offset | Size (Bytes) | Description |
|--------|--------------|--------------------------------------------------------------------------------|
| 0x00 | 1 | 0x05: Number of subblocks USB 0x04: Number of subblocks UART ⁽¹⁾ |

⁽¹⁾ The checksum subblock is not transmitted over the UART.

Table 27-19. ID Subblock

| Offset | Size (Bytes) | Description |
|--------|--------------|---------------------------------------------------------------------------|
| 0x01 | 1 | 0x01: Subblock ID |
| 0x02 | 1 | 0x05: Subblock size |
| 0x03 | 1 | 0x01: Fixed value |
| 0x04 | 2 | 0x44, 0x30: OMAP4430 device |
| 0x06 | 1 | 0x07: CH enabled (read from eFuse) 0x17: CH disabled (read from eFuse) |
| 0x07 | 1 | ROM revision |

Table 27-20. Checksum Subblock⁽¹⁾

| Offset | Size (Bytes) | Description |
|--------|--------------|-------------------|
| 0x46 | 1 | 0x15: Subblock ID |

⁽¹⁾ The checksum subblock is not transmitted over the UART.

Table 27-20. Checksum Subblock⁽¹⁾ (continued)

| Offset | Size (Bytes) | Description |
|--------|--------------|---------------------------|
| 0x47 | 1 | 0x09: Subblock size |
| 0x48 | 1 | 0x01: Fixed value |
| 0x49 | 4 | ROM CRC |
| 0x4D | 4 | 0x00000000: For GP device |

Table 27-21. Booting Messages

| Message Name | Value | Description |
|-----------------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Peripheral boot | 0xF0030002 | Continue peripheral booting. |
| Get ASIC ID | 0xF0030003 | ASIC ID request. The Get ASIC ID request message is optional. If received, the ROM code sends its ASIC ID data to the host in return. The host can issue the Get ASIC ID message multiple times if required. The structure of the ASIC ID is described in Table 27-17 . |
| Change device | 0xF003xx06 | Skip current peripheral booting and continue booting from device type indicated by xx: 0x00: Void, no device 0x01: XIP memory 0x02: XIPWAIT memory (wait-signal monitoring on) 0x03: NAND 0x04: OneNAND 0x05: MMC1 0x06: MMC2(1) 0x07: MMC2(2) 0x08: EMIF 0x43: UART 3 0x45: USB (internal transceiver) 0x46: USB-ULPI Others: Reserved |
| Next device | 0xFFFFFFFF | Skip current device and move to the next device on the device list. |
| Memory booting | Others | Skip current peripheral booting and move to the first device for memory booting. |

Figure 27-13 shows the peripheral booting procedure.

Figure 27-13. Peripheral Booting Procedure

init-010

27.4.5.2 UART

The ROM code supports booting from a UART interface with the following characteristics:

- UART interface 3
- Communication parameters set to 115.2 Kbps, 8 bits, even parity, 1 stop-bit
- Two-pin interface: RX/TX
- The boot message default time-out is 300 ms (time-out boot message)

27.4.5.3 USB

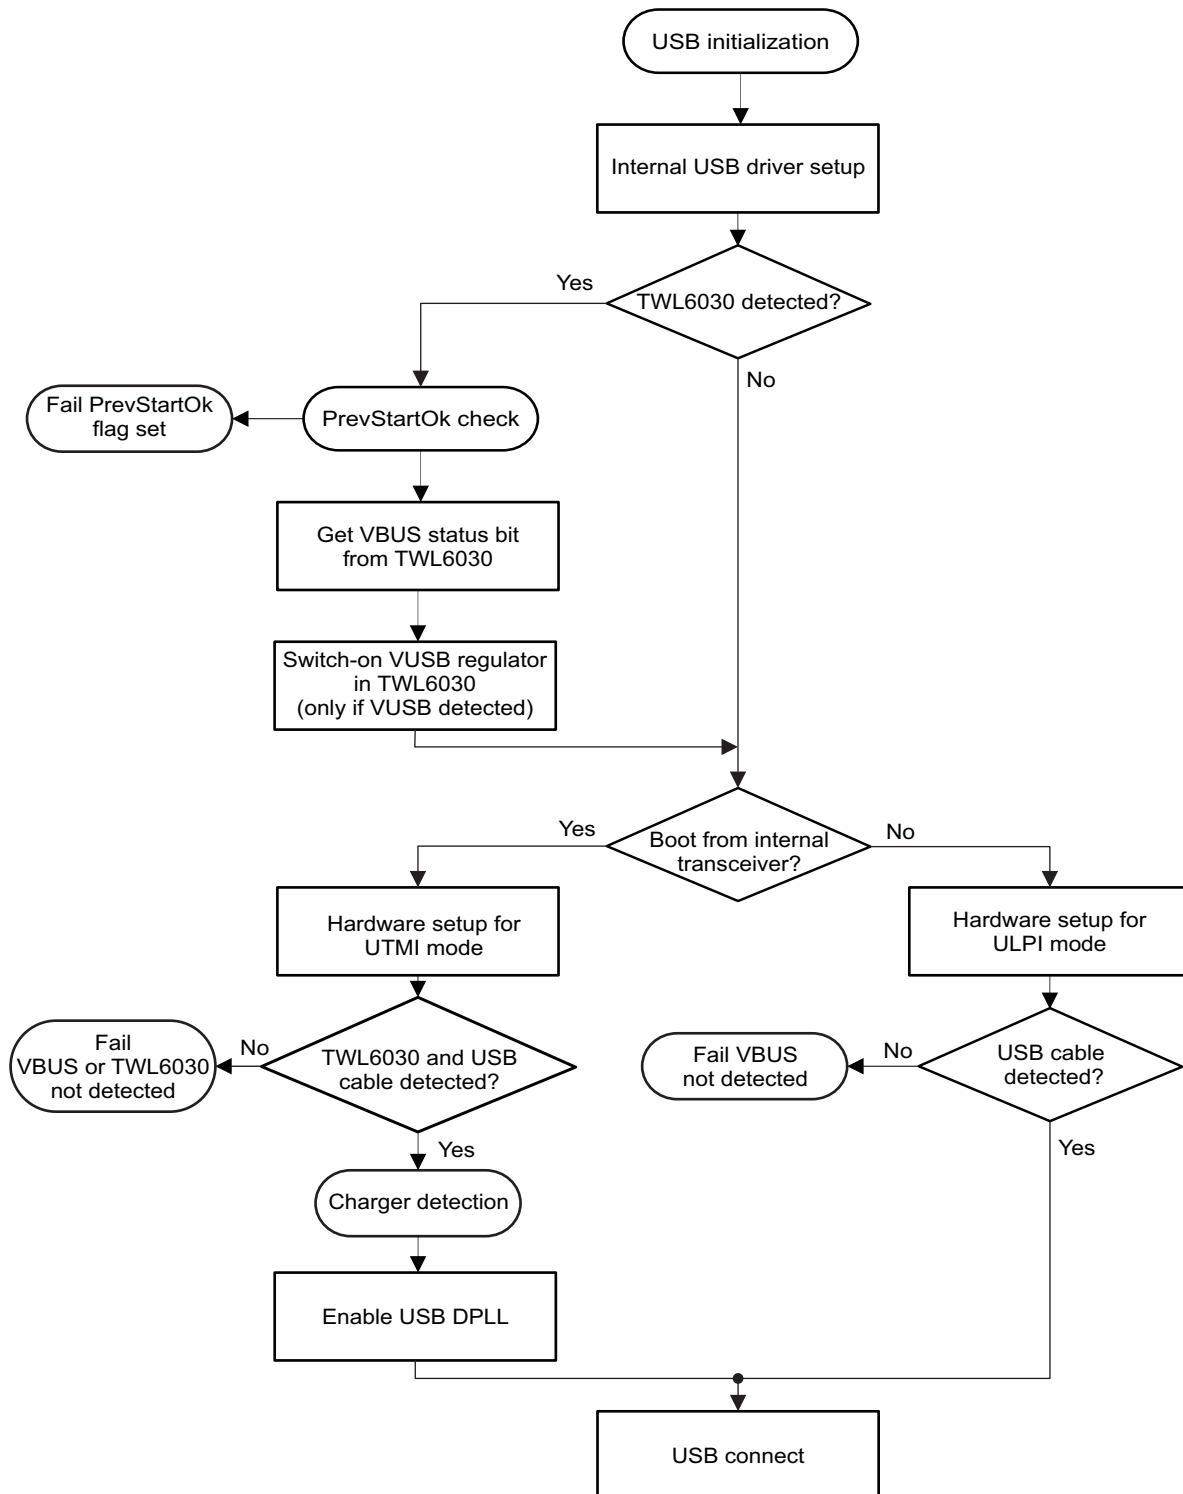

The ROM code supports booting from a USB interface with the following characteristics:

- HSUSBOTG interface (USBA0)
- Integrated transceiver (USBPHY) or external transceiver through the ULPI
- Enumeration default time-out is 3 s (timeout USB)
- The boot message default time-out is 3 s (timeout boot message).

NOTE: Even though using an OTG capable hardware, the ROM code does not handle any OTG-specific features.

27.4.5.3.1 Overview

[Figure 27-14](#) shows the USB initialization procedure.

Figure 27-14. USB Initialization Procedure

init-037

After internal USB module driver setup, the TWL6030 power IC is checked for presence. If found, the following actions are performed using I²C transactions through the I2C1 interface:

- PrevStartOk status flag check, as described in [Section 27.4.5.3.2](#).
- Get the VBUS status reflecting presence (or not) of the USB cable

- If VBUS was detected, then the VUSB regulator is enabled to power the internal transceiver.

In case of boot from external transceiver in accordance with the chosen SYSBOOT configuration:

- The HSUSBOTG hardware and PRCM clocks are configured for ULPI mode.
- The ROM code continues with the USB procedure only if the USB cable is detected (that is, VBUS is detected at external transceiver level and communicated as such through the ULPI traffic). If not, the initialization procedure is aborted.

NOTE: The USB DPLL is not set up in case of ULPI mode, for which the 60-MHz clock is driven by the external transceiver.

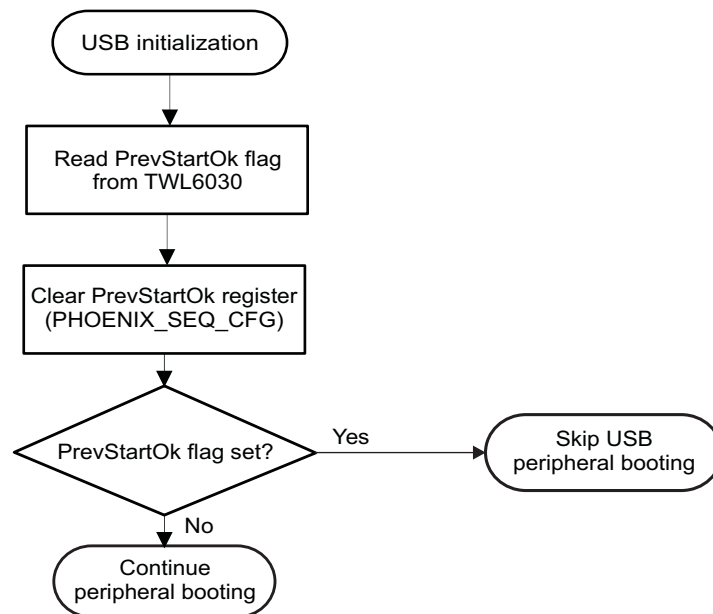

In case of boot from internal transceiver in accordance with the chosen SYSBOOT configuration:

- The USBOTGHS hardware and PRCM clocks are configured for UTMI mode and internal PHY clocks are enabled.
- The ROM code continues with the USB procedure only if TWL6030 (or emulator) is detected and the USB cable is detected (that is, VBUS is detected at the TWL6030 level and read as such with a register read through I²C). If not, the initialization procedure is aborted.
- The ROM code proceeds with charger detection, as described in [Section 27.4.5.3.2](#).
- It enables the USB DPLL for feeding the appropriate 60-MHz clock needed by the internal transceiver.

27.4.5.3.2 PrevStartOk Status Flag Check

The ROM code supports a mechanism for avoiding the boot time spent because of the enumeration time-out (default 3 s) in case the USB cable is attached and the USB option is present in the selected boot list but is not intended to initiate a peripheral booting procedure (for example, firmware update or flashing). This mechanism is jointly handled with the support of the TWL6030 (not supported if TWL6030 is not detected). This mechanism is supported only for USB and not UART (see [Figure 27-15](#), *PrevStartOk Mechanism*).

Figure 27-15. PrevStartOk Mechanism

init-038

The ROM code first checks the value of a register in the TWL6030 RTC domain (hence, retained by the backup battery when the platform is switched off) by means of an I²C read access. If the PrevStartOk bit in this register is set, the USB peripheral booting is simply skipped. In any case, the bit is reset (zeroed) by the ROM code, which means that the USB peripheral boot is re-enabled on the next cold reset (or warm reset if suitable software booting configuration is present). The initial software of the user must set this bit again by an I²C write access to disable USB peripheral booting on a subsequent reset. For more information about the accesses made towards PrevStartOk in the PHOENIX_SEQ_CFG register, see TWL6030 documentation.

27.4.5.3.3 Charger Detection

The ROM code proceeds with charger detection as part of the USB peripheral booting procedure and in compliance with the *Battery Charging Specification Revision 1.1*. It uses the specific charger detection hardware embedded in the OMAP device. Figure 27-16 shows the high-level procedure.

Figure 27-16. Charger Detection

The hardware charger detection mechanism should end up within the 500-ms time-out. The main goal of such detection is to gate the charger circuitry in TWL6030 in case a charger is not detected and a suspend event is detected on the OMAP side, for which the power consumption must be reduced.

27.4.5.3.4 SUSPEND and RESUME Handling

The SUSPEND event is detected by the HSUSBOTG module when activity on the bus stops for at least 3 ms. During peripheral booting time, a SUSPEND event is detected by the ROM code and processed by initiating a write into the TWL6030 to gate the charging circuitry. The ROM code releases the TWL6030 charger circuitry upon getting a RESUME event. During run time, SUSPEND and RESUME interrupts can be routed to the initial software for defining custom handling.

27.4.5.3.5 USB Driver Descriptors

USB devices report their attributes using descriptors. A descriptor is a data structure with a defined format. Each descriptor begins with a byte-wide field that contains the total number of bytes in the descriptor followed by a byte-wide field that identifies the descriptor type. Using descriptors allows concise storage of the attributes of individual configurations so that each configuration can reuse descriptors or portions of descriptors from other configurations that have the same characteristics. Where appropriate, descriptors contain references to string descriptors. String descriptors contain displayable, human-readable description information. These descriptor details can be used for tool development or debugging:

- Device descriptor

A device descriptor contains general information about a USB device, including global information that applies to the device and all device configurations. A USB device has only one device descriptor. A device-qualifier descriptor is required because the ROM code uses the HS feature of the USB core. [Table 27-22](#) lists the device descriptors.

Table 27-22. Device Descriptor

| Field | Value | Description |
|--------------------|------------------------------------------|-----------------------------------------------------------------------|
| bLength | 0x12 | Size of this descriptor in bytes |
| bDescriptorType | 0x01 | Device descriptor type |
| bcdUSB | 0x0210 | USB specification release number in binary coded decimal (BCD) format |
| bDeviceClass | Vendor-specific (0xFF) | Class code |
| bDeviceSubClass | Vendor-specific (0xFF) | Subclass code |
| bDeviceProtocol | Vendor-specific (0xFF) | Protocol code |
| bMaxPacketSize0 | 0x40 | Maximum packet size for endpoint 0 |
| idVendor | 0x0451 | Vendor ID (Texas Instruments), TI default value |
| idProduct | 0xD00F | Product ID (OMAP4430), TI default value |
| bcdDevice | 0x0000 | Device release number |
| iManufacturer | See Section 27.4.5.3.6 . | Index of string descriptor describing manufacturer |
| iProduct | See Section 27.4.5.3.6 . | Index of string descriptor describing product |
| iSerialNumber | See Section 27.4.5.3.6 . | Index of string descriptor describing device serial number |
| bNumConfigurations | 0x01 | Number of possible configurations |

- Device-qualifier descriptor

The device-qualifier descriptor contains information about a HS-capable device that changes if the device operates at its other speed. This descriptor is retrieved by the host using the `GetDescriptor()` request (standard device request). [Table 27-23](#) describes a device-qualifier descriptor.

Table 27-23. Device-Qualifier Descriptor

| Field | Value | Description |
|--------------------|--------|-----------------------------------------|
| bLength | 0x0a | Size of this descriptor in bytes |
| bDescriptorType | 0x06 | Device-qualifier descriptor type |
| bcdUSB | 0x0210 | USB specification release number in BCD |
| bDeviceClass | 0xFF | Class code |
| bDeviceSubClass | 0xFF | Subclass code |
| bDeviceProtocol | 0xFF | Protocol code |
| bMaxPacketSize0 | 0x40 | Maximum packet size for endpoint 0 |
| bNumConfigurations | 0x01 | Number of possible configurations |
| bReserved | 0x00 | Reserved for future use |

- Configuration descriptor

This descriptor gives information about a specific device configuration. It describes the number of interfaces supported by the configuration (see [Table 27-24](#)).

Table 27-24. Configuration Descriptor

| Field | Value | Description |
|---------------------|-------|-----------------------------------------------------------------------------|
| bLength | 0x09 | Size of this descriptor in bytes |
| bDescriptorType | 0x02 | Configuration descriptor type |
| wTotalLength | – | Combined length of all descriptors |
| bNumInterfaces | 0x01 | Number of interfaces supported |
| bConfigurationValue | 0x01 | Value to use as an argument for the <code>SetConfiguration()</code> request |
| iConfiguration | Index | Index of string descriptor describing this configuration |

Table 27-24. Configuration Descriptor (continued)

| Field | Value | Description |
|--------------|-------|---------------------------------------------|
| bmAttributes | 0xC0 | Power setting and remote wakeup |
| bMaxPower | 0x32 | Maximum power consumption of the USB device |

- Other speed configuration descriptor
This descriptor describes the configuration of a HS-capable device if it operates at its other possible speed (see [Table 27-25](#)).

Table 27-25. Other Speed Configuration Descriptor

| Field | Value | Description |
|---------------------|-------|----------------------------------------------------------------|
| bLength | 0x09 | Size of this descriptor in bytes |
| bDescriptorType | 0x07 | Other speed configuration descriptor type |
| wTotalLength | – | Combined length of all descriptors |
| bNumInterfaces | 0x01 | Number of interfaces supported |
| bConfigurationValue | 0x01 | Value to use as an argument for the SetConfiguration() request |
| iConfiguration | Index | Index of string descriptor describing this configuration |
| bmAttributes | 0xC0 | Power setting and remote wakeup |
| bMaxPower | 0x32 | Maximum power consumption of the USB device |

- Interface descriptor
This descriptor describes a specific interface in a configuration (see [Table 27-26](#)).

Table 27-26. Interface Descriptor

| Field | Value | Description |
|--------------------|-------|------------------------------------------------------|
| bLength | 0x09 | Size of this descriptor in bytes |
| bDescriptorType | 0x04 | Interface descriptor type |
| bInterfaceNumber | 0x00 | Number of this descriptor |
| bAlternateSetting | 0x00 | Value to select the alternate setting |
| bNumEndpoints | 0x02 | Number of endpoints used for this interface |
| bInterfaceClass | 0xFF | Class code |
| bInterfaceSubClass | 0xFF | Subclass code |
| bInterfaceProtocol | 0xFF | Protocol code |
| iInterface | Index | Index of string descriptor describing this interface |

- Endpoint descriptor
Each endpoint used for an interface has its own descriptor. This descriptor contains information required by the host to determine the bandwidth requirements of each endpoint. This descriptor is returned as part of the GetDescriptor(Configuration) request. (see [Table 27-27](#) and [Table 27-28](#)).

Table 27-27. BULK IN Endpoint Descriptor

| Field | Value | Description |
|------------------|----------------------|---------------------------------------------|
| bLength | 0x07 | Size of this descriptor in bytes |
| bDescriptorType | 0x05 | Endpoint descriptor type |
| bEndpointAddress | 0x81 (1 IN) | Address of the endpoint on the USB device |
| bmAttributes | 0x02 (Bulk) | Type of transfer |
| wMaxPacketSize | See ⁽¹⁾ . | Number of endpoints used for this interface |
| bInterval | 0x00 | Maximum NAK rate |

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

Table 27-28. BULK OUT Endpoint Descriptor

| Field | Value | Description |
|------------------|----------------------|---------------------------------------------|
| bLength | 0x07 | Size of this descriptor in bytes |
| bDescriptorType | 0x05 | Endpoint descriptor type |
| bEndpointAddress | 0x01 (1 OUT) | Address of the endpoint on the USB device |
| bmAttributes | 0x02 (Bulk) | Type of transfer |
| wMaxPacketSize | See ⁽¹⁾ . | Number of endpoints used for this interface |
| bInterval | 0x00 | Maximum NAK rate |

⁽¹⁾ The maximum size is 0x0200 (512 bytes) for HS bulk endpoint and 0x0040 (64 bytes) for FS bulk endpoint.

- String descriptors

String descriptors use UNICODE encoding. The strings in a USB device can support multiple languages. When requesting a string descriptor, the requester specifies the desired language using a 16-bit language ID (LANGID) defined by the USB interface. String index 0 for all languages returns a string descriptor that contains an array of 2-byte LANGID codes supported by the device.

For the description of the different string descriptors, see:

- The language ID string descriptor ([Table 27-29](#))
- The manufacturer ID string descriptor ([Table 27-30](#))
- The product ID string descriptor ([Table 27-31](#))
- The configuration string descriptor ([Table 27-32](#))
- The interface string descriptor ([Table 27-33](#))

Table 27-29. Language ID String Descriptor

| Field | Value | Description |
|-----------------|---------------------|----------------------------------|
| bLength | 0x04 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| wLangId | 0x0409 (US English) | Language ID code |

Table 27-30. Manufacturer ID String Descriptor

| Field | Value | Description |
|-----------------|-------------------|----------------------------------|
| bLength | 0x24 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| bString | Texas Instruments | Manufacturer string |

Table 27-31. Product ID String Descriptor

| Field | Value | Description |
|-----------------|----------|----------------------------------|
| bLength | 0x12 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| bString | OMAP4430 | Product string |

Table 27-32. Configuration String Descriptor

| Field | Value | Description |
|-----------------|-------|----------------------------------|
| bLength | 0x08 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| bString | pbcb | Configuration string |

Table 27-33. Interface String Descriptor

| Field | Value | Description |
|-----------------|-------|----------------------------------|
| bLength | 0x08 | Size of this descriptor in bytes |
| bDescriptorType | 0x03 | String descriptor type |
| bString | pbi | Interface string |

27.4.5.3.6 USB Customized Descriptors

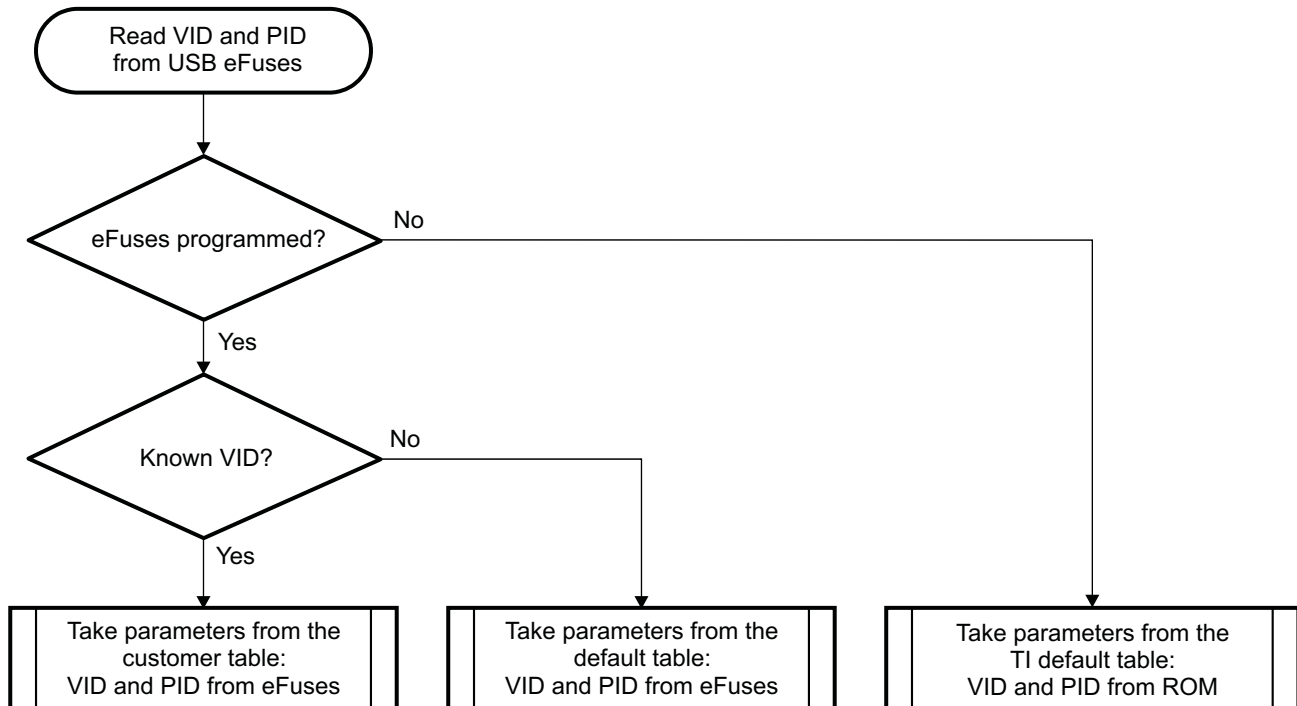

There are two parameters in USB descriptors that customers can define after the chip is created: vendor ID (VID) and product ID (PID). The ROM code uses dedicated eFuses that hold VID and PID values. Other parameters can also be changed based on the VID value. The ROM code has an encoded set of parameters for customers who have defined their requirements before the ROM code has been done. [Table 27-34](#) lists the parameters that depend on the VID value.

Table 27-34. Customized Descriptor Parameters

| Parameter | Size (Bytes) | Default Values (From eFuses) | TI Default Values (From ROM) |
|-----------------|--------------|------------------------------|------------------------------|
| Device ID code | 2 | 0x0000 | 0x0000 |
| Device class | 1 | 0xFF | 0xFF |
| Device subclass | 1 | 0xFF | 0xFF |
| Device protocol | 1 | 0xFF | 0xFF |
| Manufacturer | String | N/A | Texas Instruments |
| Product | String | OMAP4430 | OMAP4430 |
| Serial number | String | See ⁽¹⁾ | See ⁽¹⁾ |

⁽¹⁾ The standard device descriptor indicates that the device has no serial number.

[Figure 27-17](#) shows an additional customer parameter selection method. It is based on the VID burned in the USB eFuses.

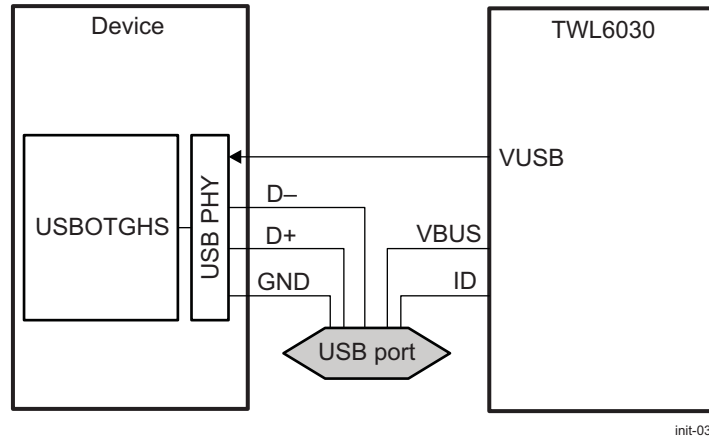

Figure 27-17. Customer USB Descriptor Selection

init-011

27.4.5.3.7 System Interconnection – Integrated Transceiver

When SYSBOOT selects the embedded PHY, the USB power/data path can be described as shown in Figure 27-18.

Figure 27-18. USB System Using Internal Transceiver

27.4.5.3.8 System Interconnection - External Transceiver

The USBOTGHS module uses the ultralow-pin-count interface (ULPI) to interconnect with an external USB transceiver. In this case, the ROM code does not interact with the transceiver. Thus, users must ensure that the transceiver power supply and clock are present and the transceiver is out of reset.

27.4.5.3.9 USB Driver Functionality

- Transactions supported:
 - Control transactions: Used for standard device requests
 - Bulk transactions: Used for data transfer in the image downloading stage. The ASIC ID is sent to the Bulk IN endpoint and the image is transferred from the host over the Bulk OUT endpoint.

The OMAP USB device first attaches to the host as an FS device. In the reset mechanism, the USB core requests HS operation. If the HS negotiation in the reset phase is successful, further transactions are at HS; otherwise, they are at FS. After reset, the USB driver checks for the speed of the device, whether it is FS or HS. Depending on the speed configured by the host, the standard USB device requests are answered with the corresponding descriptors.

- Standard device request restrictions:

Some standard device requests are not supported by the driver because the USB driver is dedicated for use by the ROM code for peripheral booting. Table 27-35 lists the standard device requests supported by the driver.

Table 27-35. Standard Device Requests Supported

| Request | Description | Support |
|-------------------|--------------------------------------------------------------------|---------------------------------------------------|
| CLEAR_FEATURE | Sets/clears a specific feature | Supported only for ENDPOINT_HALT feature |
| GET_CONFIGURATION | Returns the current device configuration value | Yes |
| GET_DESCRIPTOR | Returns the specified descriptor | Yes |
| GET_INTERFACE | Returns the selected alternate setting for the specified interface | Yes |
| GET_STATUS | Returns the status for the specified recipient | Yes |
| SET_ADDRESS | Sets the device address | Yes |
| SET_CONFIGURATION | Sets the device configuration | Yes |
| SET_DESCRIPTOR | Updates existing descriptors or adds new descriptors | Runtime updating of descriptors is not supported. |

Table 27-35. Standard Device Requests Supported (continued)

| Request | Description | Support |
|---------------|----------------------------------------------------|---------------------------------------------------------|
| SET_FEATURE | Sets or enables a specific feature | Supported only for ENDPOINT_HALT feature |
| SET_INTERFACE | Selects an alternate setting in an interface | Runtime setting of alternate features is not supported. |
| SYNCH_FRAME | Sets and reports an endpoint synchronization frame | No, because isochronous transfers are not used |

27.4.6 Fast External Booting

27.4.6.1 Overview

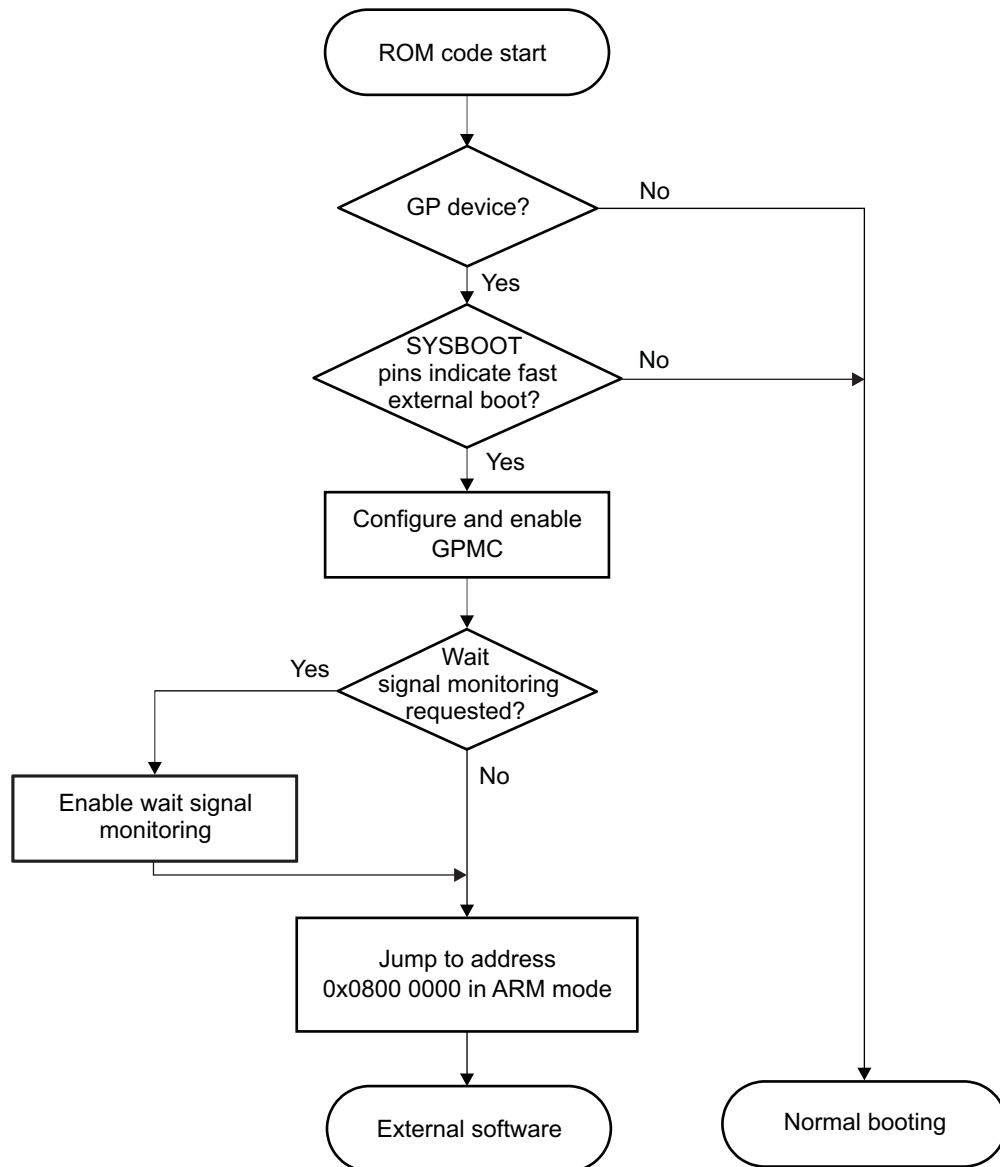

The fast external boot is a special memory booting mode, possible only on GP devices. It consists of a blind jump to a code in an external XIP memory device connected to GPMC CS0. Fast external booting is set up by means of the SYSBOOT configuration pins and lets customers create their own booting code.

The jump is performed with minimum on-chip ROM code execution.

27.4.6.2 Fast External Booting Procedure

[Figure 27-19](#) shows the fast external boot procedure. The code is at the beginning and is written in assembly. The code does not use any RAM and is designed for fast execution.

Figure 27-19. Fast External Boot Procedure

init-013

27.4.7 Memory Booting

27.4.7.1 Overview

The memory booting process starts an external code in memory devices. Only memory type of booting devices can be used by ROM code as permanent booting devices (that is, devices examined after both cold (POR) and warm resets). Temporary booting devices are examined only after cold resets. The supported permanent booting devices are:

- NOR flash devices
- NAND flash devices
- OneNAND/Flex-OneNAND devices
- eMMC/eSD embedded flash memories
- SD/MMC flash cards
- LPDDR2-NVM

Two main groups of permanent booting devices are distinguished by code shadowing. Code shadowing means copying code from a nondirectly addressable device (non-XIP) to RAM, where the code can be executed. Directly addressable devices are XIP devices.

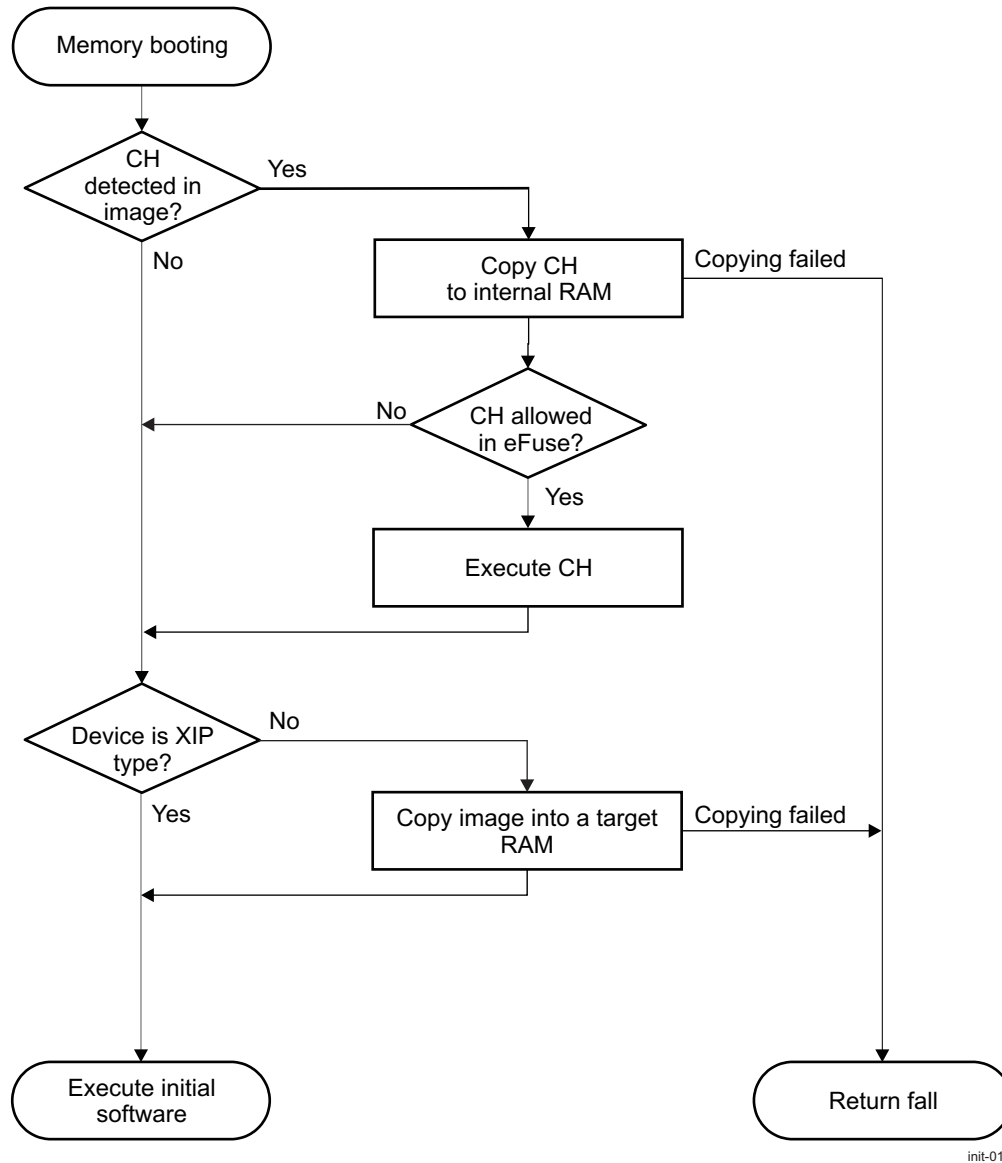

[Figure 27-20](#) shows the general memory booting procedure common to all types of devices. First, CH is copied to internal RAM. It is copied even for XIP devices, because the OMAP device can temporarily lose a connection with XIP memory during CH execution. The second step is to shadow the image, if the device is not XIP. The last step is image execution and any return from image results in a dead loop.

If CH copying or shadowing fails, memory booting returns to the main booting procedure, which selects the next device for booting.

During the first read sector (512 bytes) call, sectors are copied to a temporary RAM buffer. Once the image is found and the destination address is known, the content of the temporary buffer is moved to the target RAM location so it is required to reread the first image sector. On a GP device, the GP header is discarded; therefore, only executable code is located in RAM, with the first executable instruction located at the destination address.

eMMC/eSD embedded memories, MMC/SD cards, NAND, and OneNAND/Flex-OneNAND devices can hold up to four copies of the booting image. Therefore, the ROM code searches for one valid image out of the four, if present, by walking over the first blocks of mass storage space. Other XIP devices (NOR) use only one copy of the booting image.

Figure 27-20. Memory Booting Procedure

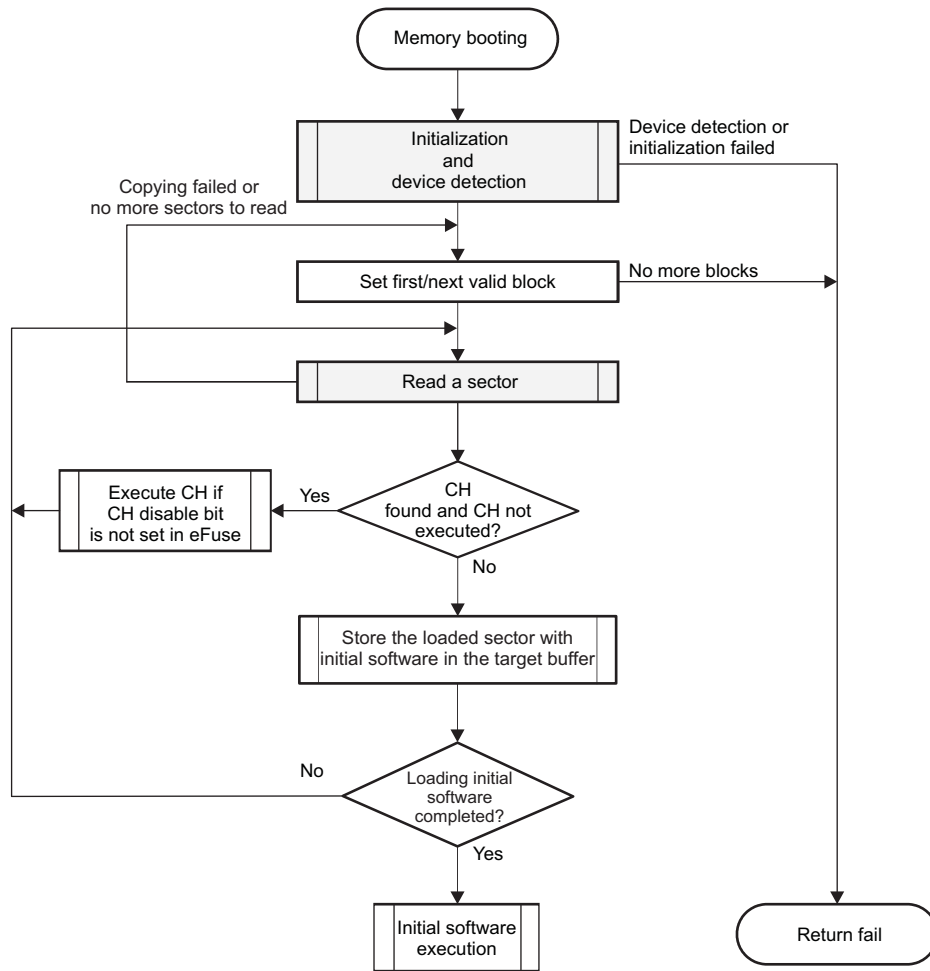

init-014

27.4.7.2 Non-XIP Memory

Figure 27-21 shows the procedure used when memory booting runs with non-XIP devices. The grayed procedures are specific to each device. NAND and OneNAND/Flex-OneNAND devices use up to four copies of the image in the first four physical blocks. Therefore, the ROM code searches for the image in the first four physical blocks of these devices. Other devices use only one copy of the image and the block loop runs only once.

During image shadowing on a GP device, the CH is expected to be in a separate sector before the initial software.

Figure 27-21. Image Shadowing on GP Device

init-015

Table 27-36 summarizes the number of blocks and sectors searched during memory booting from devices requiring image shadowing. A sector is assumed to be 512 bytes long. NANDs and OneNAND/Flex-OneNAND are organized with blocks, which are erasable units. MMC/SD/eMMC/eSD + FAT12/16/32 booting consists of reading a file.

Table 27-36. Blocks and Sectors Searched on Non-XIP Memories

| Memory | Maximum Number of Checked Blocks | Number of Sectors Searched |
|-------------------------------|----------------------------------|---------------------------------------------|
| NAND | First 4 | Number of sectors in a block ⁽¹⁾ |
| OneNAND/Flex-OneNAND | First 4 | 8 |
| eMMC/eSD raw | First 4 | 1 |
| MMC/SD raw | First 4 | 1 |
| MMC/SD/eMMC/eSD + FAT12/16/32 | 1 File | |

⁽¹⁾ Depends on NAND geometry

For more information about the GPMC module, see [Section 15.4, GPMC Overview](#).

The following sections describe the supported device types.

27.4.7.3 XIP Memory

The ROM code can boot directly from XIP devices, such as NOR flash memories, that have the following characteristics:

- The GPMC is the communication interface.
- Memories up to 1 Gb (128MB) can be connected.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- The GPMC clock is 50 MHz.
- The device is connected to CS0 mapped to address 0x0800 0000.
- The wait pin signal gpmc_wait0 is monitored according to the sys_boot configuration pins.

Depending on the SYSBOOT option, the GPMC can be configured to use the wait signal connected to the gpmc_wait0 pin. Wait pin polarity is set to stall accessing memory when gpmc_wait0 is low. Wait-signal monitoring is used with memories that require a long time for initialization after reset, or that must pause while reading data.

For an XIP memory booting, no user intervention is required; the following debugging steps are described. Only CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device.

Booting from an XIP device consists of the following steps:

1. Configure the GPMC for XIP device access.
2. Verify that the CH is present at address 0x0800 0000. If it is, copy the entire sector (512 bytes) to internal RAM and execute CH.
3. Set the image location:
 - 0x0800 0000 if the CH is not found
 - 0x0800 0200 if the CH is found
4. Verify that a bootable image is at the image location.
5. Execute the image if it is found.
6. If the image is not found, return from XIP booting to the main booting loop.

27.4.7.3.1 GPMC Initialization

[Table 27-37](#) lists the timing settings of the GPMC when set for XIP and other address-data accessible devices, such as OneNAND/Flex-OneNAND. [Table 27-37](#) is included for debug information.

Table 27-37. XIP Timing Parameters

| Parameter | Value [Clock Cycles] ⁽¹⁾ | Register Initialization (where i = 0–7) | Reset Value |
|--------------------|-------------------------------------------|----------------------------------------------------------------|-------------|
| Write cycle period | 17 | The GPMC_CONFIG5_i[12:8] WRCYCLETIME bit field is set to 0x11. | 0x11 |
| Read cycle period | 17 | The GPMC_CONFIG5_i[4:0] RDCYCLETIME bit field is set to 0x11. | 0x11 |
| CS low time | 1 | The GPMC_CONFIG2_i[3:0] CSONTIME bit field is set to 0x1. | 0x1 |
| CS high time | 16 | The GPMC_CONFIG2_i[12:8] CSRDOFFTIME bit field is set to 0x10. | 0x10 |
| ADV low time | 1 | The GPMC_CONFIG3_i[3:0] ADVONTIME bit field is set to 0x1. | 0x1 |
| ADV high time | 2 | The GPMC_CONFIG3_i[12:8] ADVRDOFFTIME bit field is set to 0x2. | 0x2 |
| OE low time | 3 | The GPMC_CONFIG4_i[3:0] OEONTIME bit field is set to 0x3. | 0x6 |
| OE high time | 16 | The GPMC_CONFIG4_i[12:8] OEOFFTIME bit field is set to 0x10. | 0x10 |
| WE low time | 3 | The GPMC_CONFIG4_i[19:16] WEONTIME bit field is set to 0x3. | 0x05 |

⁽¹⁾ The one clock cycle is 20 ns, which corresponds to 50-MHz frequency.

Table 27-37. XIP Timing Parameters (continued)

| Parameter | Value [Clock Cycles] ⁽¹⁾ | Register Initialization (where i = 0–7) | Reset Value |
|-----------------|-------------------------------------------|-----------------------------------------------------------------|-------------|
| WE high time | 15 | The GPMC_CONFIG4_i[28:24] WEOFFTIME bit field is set to 0xF. | 0x10 |
| Data latch time | 15 | The GPMC_CONFIG5_i[20:16] RDACCESSTIME bit field is set to 0xF. | 0x0F |

There is no specific identification routine executed before booting from an XIP device.

27.4.7.4 NAND

NAND flash memory is not an XIP device; it requires shadowing before the code can be executed. ROM code support for the NAND flash devices has the following characteristics:

- The GPMC is the communication interface.
- Device from 512 Mbit (64MB)
- x8 and x16 bus width
- Support for large page size (2048 bytes + 64 spare bytes) or very large page size 4096 bytes + 128/218 spare bytes)
- Chip enable (CE) don't care devices only
- Single-level cell (SLC) and multilevel cell (MLC) devices
- Device identification based on ONFI or ROM table
- ECC correction: 8 bits/sector for most devices (16 bits/sector for devices with large spare area)
- GPMC timings are adjusted for NAND access.
- The GPMC clock is 50 MHz.
- The device is connected to CS0.
- The wait pin signal gpmc_wait0 is connected to the NAND BUSY output.
- Four physical blocks are searched for an image. Block size depends on the device.

For NAND memory booting, no user intervention is needed; the information in the following subsections is included for debugging. Only the CH, which is not mandatory, lets the user change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

27.4.7.4.1 Initialization and NAND Detection

The initialization routine for NAND consists of three parts: GPMC initialization, device detection with parameter determination, and bad block detection.

- GPMC initialization

The GPMC interface is configured so that it can access NAND. Because NAND memories do not need the address bus, it is released. The data bus width is initially set to 8 bits. If necessary, it is changed to 16 bits after the device parameters are determined. [Table 27-38](#) shows the GPMC configuration used during NAND boot. [Table 27-38](#) is included for debug information.

Table 27-38. NAND Timing Parameters

| Parameter | Value (Clock Cycles) | Register Initialization (where i = 0–7) | Reset Value |
|------------------------|----------------------|-----------------------------------------|-------------|
| Write cycle time | 20 | GPMC_CONFIG5_i[12:8] WRCYCLETIME = 0x14 | 0x11 |
| Read cycle time | 20 | GPMC_CONFIG5_i[4:0] RDCYCLETIME = 0x14 | 0x11 |
| CS low time | 0 | GPMC_CONFIG2_i[3:0] CSONTIME = 0x0 | 0x1 |
| CS low to OE low time | 5 | GPMC_CONFIG4_i[3:0] OEONTIME = 0x5 | 0x6 |
| CS low to OE high time | 16 | GPMC_CONFIG4_i[12:8] OEOFFTIME = 0x10 | 0x10 |

Table 27-38. NAND Timing Parameters (continued)

| Parameter | Value (Clock Cycles) | Register Initialization (where i = 0–7) | Reset Value |
|---------------------------|----------------------|------------------------------------------|-------------|
| CS low to WE low time | 1 | GPMC_CONFIG4_i[19:16] WEONTIME = 0x1 | 0x5 |
| CS low to WE high time | 15 | GPMC_CONFIG4_i[28:24] WEOFFTIME = 0xF | 0x10 |
| CS low to data latch time | 14 | GPMC_CONFIG5_i[20:16] RDACCESSTIME = 0xE | 0xF |

- Device detection and parameters

The ROM code first performs an initial wait for device auto initialization (with 250-ms time-out) with polling of the ready information. Then, it needs to identify the NAND type connected to the GPMC interface. The GPMC is initialized using 8 bits, asynchronous mode. The NAND device is reset (command FFh) and its status is polled until ready for operation (with 100-ms time-out). The ONFI Read ID (command 90h/address 20h) is sent to the NAND device. If it replies with the ONFI signature (4 bytes) then a Read parameters page (command ECh) is sent. The information provided in [Table 27-39](#) is then extracted: page size, spare area size, number of pages per block, and the addressing mode. The remaining data bytes from the parameter page stream are simply ignored.

Table 27-39. ONFI Parameters Page Description

| Offset | Description | Size (Bytes) |
|--------|--------------------------------|--------------|
| 6 | Features supported | 2 |
| 80 | Number of data bytes per page | 4 |
| 84 | Number of spare bytes per page | 2 |
| 92 | Number of pages per block | 4 |
| 101 | Number of address cycles | 1 |

If the ONFI Read ID command fails (it will be the case with any device not supporting ONFI) then the device is reset again with polling for device to be ready (with 100ms timeout). Then, the standard Read ID (command 90h / address 00h) is sent. If the Device ID (2nd byte of the ID byte stream) is recognized as being a supported device then the device parameters are extracted from an internal ROM Code table. [Table 27-40](#) lists the supported devices.

Table 27-40. Supported NAND Devices

| Capacity | Device ID | Bus Width | Page Size in Bytes |
|----------|-----------|-----------|--------------------|
| 512 Mb | F0h | 8 | 2048 |
| 512 Mb | C0h | 16 | 2048 |
| 512 Mb | A0h | 8 | 2048 |
| 512 Mb | B0h | 16 | 2048 |
| 512 Mb | F2h | 8 | 2048 |
| 512 Mb | C2h | 16 | 2048 |
| 512 Mb | A2h | 8 | 2048 |
| 512 Mb | B2h | 16 | 2048 |
| 1 Gb | F1h | 8 | 2048 |
| 1 Gb | C1h | 16 | 2048 |
| 1 Gb | A1h | 8 | 2048 |
| 1 Gb | B1h | 16 | 2048 |
| 2 Gb | DAh | 8 | 2048 (4096) |
| 2 Gb | CAh | 16 | 2048 (4096) |
| 2 Gb | AAh | 8 | 2048 (4096) |
| 2 Gb | BAh | 16 | 2048 (4096) |
| 2 Gb | 83h | 8 | 2048 (4096) |
| 2 Gb | 93h | 16 | 2048 (4096) |

Table 27-40. Supported NAND Devices (continued)

| Capacity | Device ID | Bus Width | Page Size in Bytes |
|----------|-----------|-----------|--------------------|
| 4 Gb | DCh | 8 | 2048 (4096) |
| 4 Gb | CCh | 16 | 2048 (4096) |
| 4 Gb | ACh | 8 | 2048 (4096) |
| 4 Gb | BCh | 16 | 2048 (4096) |
| 4 Gb | 84h | 8 | 2048 (4096) |
| 4 Gb | 94h | 16 | 2048 (4096) |
| 8 Gb | D3h | 8 | 2048 (4096) |
| 8 Gb | C3h | 16 | 2048 (4096) |
| 8 Gb | A3h | 8 | 2048 (4096) |
| 8 Gb | B3h | 16 | 2048 (4096) |
| 8 Gb | 85h | 8 | 2048 (4096) |
| 8 Gb | 95h | 16 | 2048 (4096) |
| 16 Gb | D5h | 8 | 2048 (4096) |
| 16 Gb | C5h | 16 | 2048 (4096) |
| 16 Gb | A5h | 8 | 2048 (4096) |
| 16 Gb | B5h | 16 | 2048 (4096) |
| 16 Gb | 86h | 8 | 2048 (4096) |
| 16 Gb | 96h | 16 | 2048 (4096) |
| 32 Gb | D7h | 8 | 2048 (4096) |
| 32 Gb | C7h | 16 | 2048 (4096) |
| 32 Gb | A7h | 8 | 2048 (4096) |
| 32 Gb | B7h | 16 | 2048 (4096) |
| 32 Gb | 87h | 8 | 2048 (4096) |
| 32 Gb | 97h | 16 | 2048 (4096) |
| 64 Gb | DEh | 8 | 2048 (4096) |
| 64 Gb | CEh | 16 | 2048 (4096) |
| 64 Gb | A Eh | 8 | 2048 (4096) |
| 64 Gb | B Eh | 16 | 2048 (4096) |

After retrieving parameters from the table, the page size and block size are updated based on the fourth byte of the NAND ID data. Because of inconsistency among manufacturers, only devices recognized to be at least 2Gb have these parameters updated. Therefore, the ROM code supports 4-KB page devices, but only if their size, according to the table, is at least 2Gb. Devices that are smaller than 2Gb have the block size parameter set to 128KB (when the page size is 2KB). [Table 27-41](#) shows the fourth ID data byte encoding used in the ROM code.

Table 27-41. Fourth NAND ID Data Byte

| Item | Description | I/O Number | | | | | | | |
|--------------------------|-------------|------------|---|---|---|---|---|---|---|
| | | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Page Size | 512 bytes | | | | | | | 0 | 0 |
| | 2048 bytes | | | | | | | 0 | 1 |
| | 4096 bytes | | | | | | | 1 | 0 |
| | 8192 bytes | | | | | | | 1 | 1 |
| Cell Type ⁽¹⁾ | 2 levels | | | | | | 0 | 0 | |
| | 4 levels | | | | | | 0 | 1 | |
| | 8 levels | | | | | | 1 | 0 | |
| | 16 levels | | | | | | 1 | 1 | |

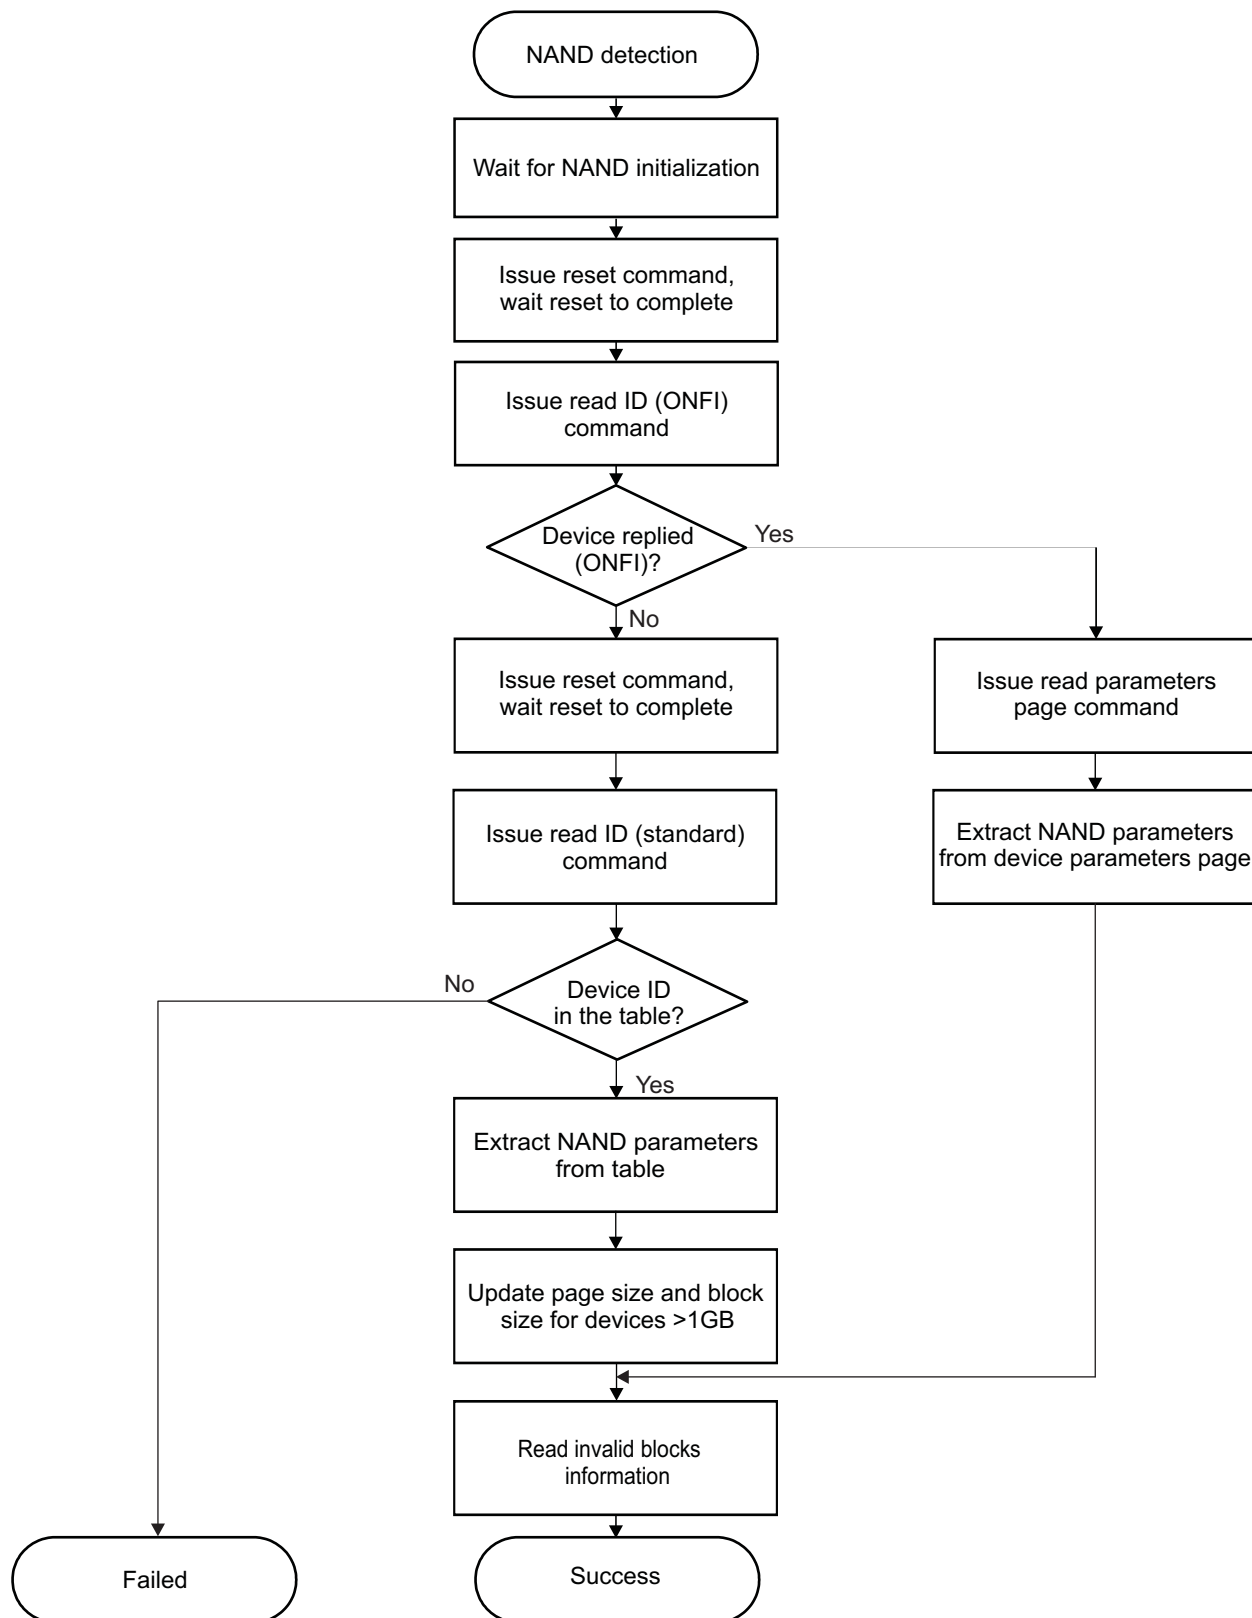

⁽¹⁾ (1) Read by ROM code only when the manufacturer code (first ID byte) is 98h

Table 27-41. Fourth NAND ID Data Byte (continued)

| Item | Description | I/O Number | | | | | | | |
|-------------------|-------------|------------|---|---|---|---|---|---|---|
| | | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Block Size | 64KB | | | 0 | 0 | | | | |
| | 128KB | | | 0 | 1 | | | | |
| | 256KB | | | 1 | 0 | | | | |
| | 512KB | | | 1 | 1 | | | | |

Figure 27-22 shows the detection procedure. Once the NAND device is successfully detected, the ROM code changes the GPMC to 16-bit bus width, if necessary.

Figure 27-22. NAND Device Detection

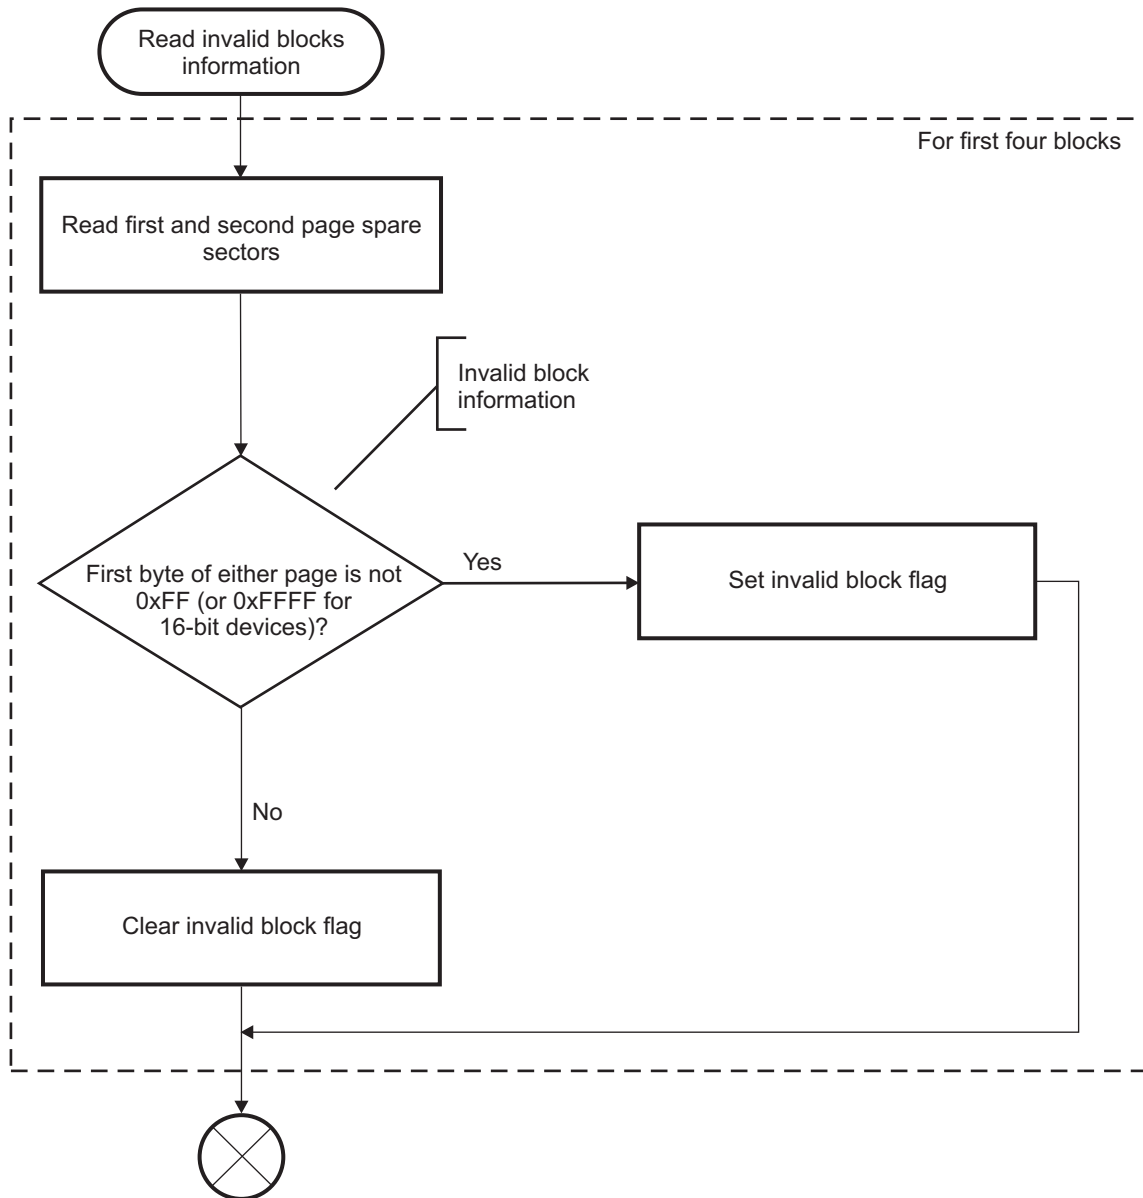

init-023

- **Bad block verification**
 Invalid blocks contain invalid bits whose reliability cannot be ensured by the manufacturer. These bits are identified in the factory or during the programming and reported in the initial invalid block information in the spare area on the first and second page of each block. Because the ROM code looks for an image in the first four blocks, it detects the validity status of these blocks. Blocks detected as invalid are not accessed later. Block validity status is coded in the spare areas of the first two pages of a block (first byte equal to FFh in the first and second pages for an 8-bit device/first word equal to FFFFh in the first and second pages for a 16-bit device).

Figure 27-23 shows the invalid block detection routine. The routine consists in reading spare areas and checking the validity data pattern.

Figure 27-23. Bad NAND Invalid Block Detection

init-033

27.4.7.4.2 Read Sector Procedure

During the booting procedure, the ROM code reads 512-byte sectors from the NAND device. The reading fails in two cases:

- The accessed sector is in a block marked as invalid.
- The accessed sector contains an error that cannot be corrected with ECC.

The ROM code uses normal read (command 00h 30h) for reading NAND page data.

Page data can contain errors caused by memory alteration. The ROM code uses an ECC correction algorithm to detect and possibly correct those errors. The default ECC correction applied is BCH 8b/sector using the GPMC and ELM hardware.

For device ID codes D3h, C3h, D5h, C5h, D7h, C7h, DEh, CEh when the manufacturer code (first ID byte) is 98h, the cell type information is checked in the 4th byte of ID data. If it is equal to 10b, the ECC correction applied is BCH 16b/sector.

The BCH data is automatically calculated by the GPMC on reading each 512-byte sector. The computed ECC is compared against the ECC stored in the spare area for the corresponding page. Depending on the page size, the amount of ECC data bytes stored in the corresponding spare area is different. [Figure 27-24](#) and [Figure 27-25](#) show the mapping of ECC data inside the spare area for 2KB-page and 4KB- page devices, respectively. If both ECC data are equal, the read sector function returns the read 512-byte sector without error. Otherwise, the ROM code tries to correct error(s) in the corresponding sector (this procedure is assisted by the ELM hardware) and returns the data if successful. If errors are uncorrectable, the function returns with FAIL.

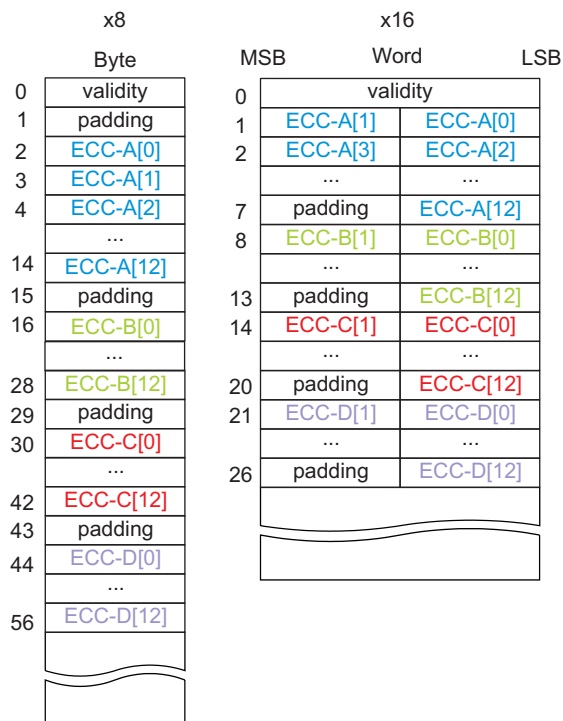

The first two bytes in the spare area are always reserved for block state information:

- First word equal to FFFFh for a 16 bits device to check block validity
- First byte equal to FFh for an 8 bits device to check block validity and the second byte is a padding

Concerning the length of ECC section in bytes, extra bytes can be added to make the access x16 compatible:

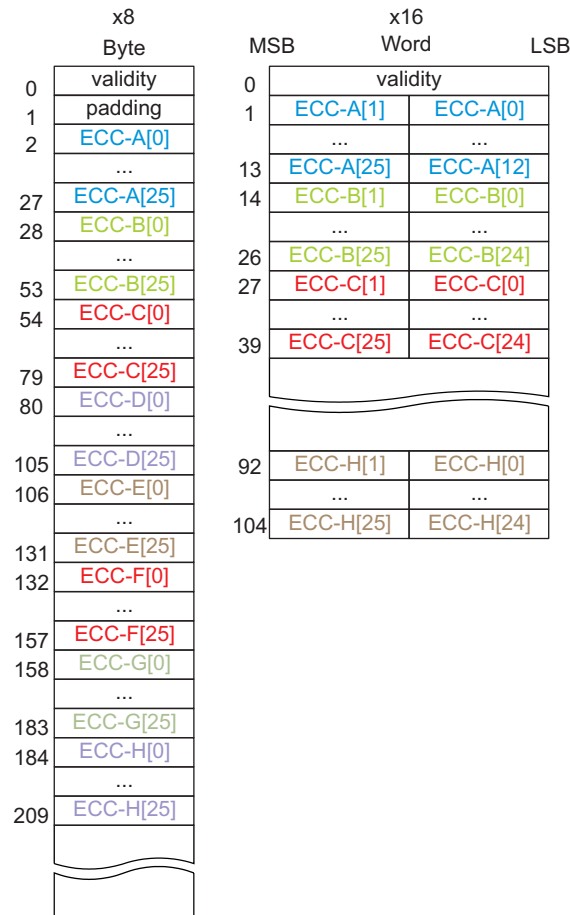

- For 8b BCH, there are 14 bytes ECC for each 512 bytes sector (that is, 13 bytes ECC + 1 byte padding)
- For 16b BCH, there are 26 bytes ECC for each 512 bytes sector (that is, no padding is needed)

Figure 27-24. ECC Data Mapping for 2-KB Page and 8b BCH Encoding

init-040

Figure 27-25. ECC Data Mapping for 4-KB Page and 16b BCH Encoding

init-041

27.4.7.5 OneNAND/Flex-OneNAND

The ROM code support for OneNAND/Flex-OneNAND devices has the following characteristics:

- Devices from 512 Mbits
- The GPMC is the communication interface.
- x16 data bus width only
- Asynchronous protocol and address/data multiplexed mode
- GPMC reset default timings are used.
- The GPMC clock is 50 MHz.
- The device is connected to GPMC CS0 mapped to address 0x0800 0000.
- The wait-pin signal gpmc_wait0 is not monitored.
- Four physical blocks are searched for image. The block size is 128KB (typically).
- Data correction is fully handled by the OneNAND/FlexOneNAND device

The OneNAND/Flex-OneNAND device is a NAND matrix coupled with RAM buffers and a NOR-type interface. ECC correction handling is done automatically by the internal state-machine. The page to be accessed is first loaded in the RAM buffer using memory-mapped registers. Then, the page is read directly from the buffer using a NOR-type interface.

For OneNAND/Flex-OneNAND memory booting, no user intervention is required. The information in the following sections is included for debugging. Only the CH, which is not mandatory, lets users change clock settings and GPMC parameters. Failure in CH copying causes a return to the main booting procedure, which selects the next device for booting.

27.4.7.5.1 Initialization and OneNAND/Flex-OneNAND Detection

The initialization routine for OneNAND/Flex-OneNAND consists of two parts: GPMC initialization and device detection with parameter determination.

- GPMC initialization

The ROM code first initializes the GPMC interface in XIP mode (that is, asynchronous 16-bit multiplexed mode). Wait signal monitoring is disabled.

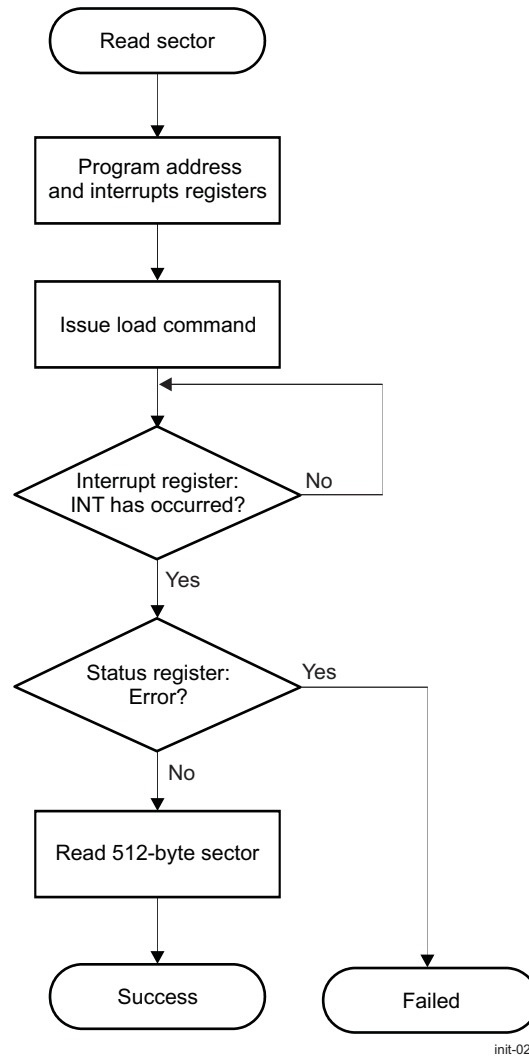

- Device detection and parameters

The ROM code identifies a OneNAND/Flex-OneNAND device by reading the device identification data. There are two ways to read identification data: using serial commands and reading from fixed memory-mapped registers. The ROM code reads identification data using both methods and compares the results. When the comparison passes, the ROM code assumes that the OneNAND/Flex-OneNAND device is connected. If the device is successfully recognized, the ROM code reads the device configuration (number and size of data buffers) and configures it for asynchronous mode (default).

27.4.7.5.2 OneNAND/Flex-OneNAND Read Sector Procedure

When booting requests a sector from the OneNAND/Flex-OneNAND device, the ROM code performs the load operation, which transfers the content of the requested sector to the data buffer RAM. The ROM code waits until the operation completes, polling the OneNAND/Flex-OneNAND interrupt register. The status register is then checked and the ROM code returns FAIL if the operation completes with an error. Otherwise, the data buffer RAM is copied to the destination buffer. [Figure 27-26](#) shows this procedure.

Figure 27-26. OneNAND/Flex-OneNAND Read Sector

27.4.7.5.3 OneNAND/Flex-OneNAND Support Limitations

As described in Section 27.4.7.5.1, *Initialization and OneNAND/Flex-OneNAND Detection*, the ROM code checks only the coherency of the device ID obtained by two different methods. There is no table of supported Flex-OneNANDs in ROM code. This removes any dependency of the ROM code on device IDs from different manufacturers. However, the driver works with the following assumption:

- Page size is assumed to be 2048 bytes, divided into four sectors of 512 bytes. In case of OneNAND/Flex-OneNAND, with pages of 4096 bytes in size, divided into eight sectors, users must program only the first sectors (sectors 0, 1, 2, 3) of each page. Sectors 4, 5, 6, and 7 of each page are not considered by the driver.

27.4.7.6 eMMC/eSD Embedded Memories and MMC/SD Cards

The OMAP device allows booting from eMMC/eSD embedded memories or MMC/SD cards connected to SD/MMC1 or SD/MMC2. The booting interface is selected by configuration of the sys_boot pins.

The HS MMC/SD/SDIO host controllers (MMCHS) handle the physical layer, while the ROM code handles the simplified logical protocol layer (read-only protocol). A limited range of commands is implemented in the ROM code.

The MMC interface 1 supports 1.8V/3V digital I/Os. The selection on I/O voltage level is done using the PBIAS circuitry. The PBIAS reference level is sensed by the ROM code and PBIAS cell voltage setup appropriately before any communication with the device. The MMC interface 2 supports only 1.8-V digital I/Os.

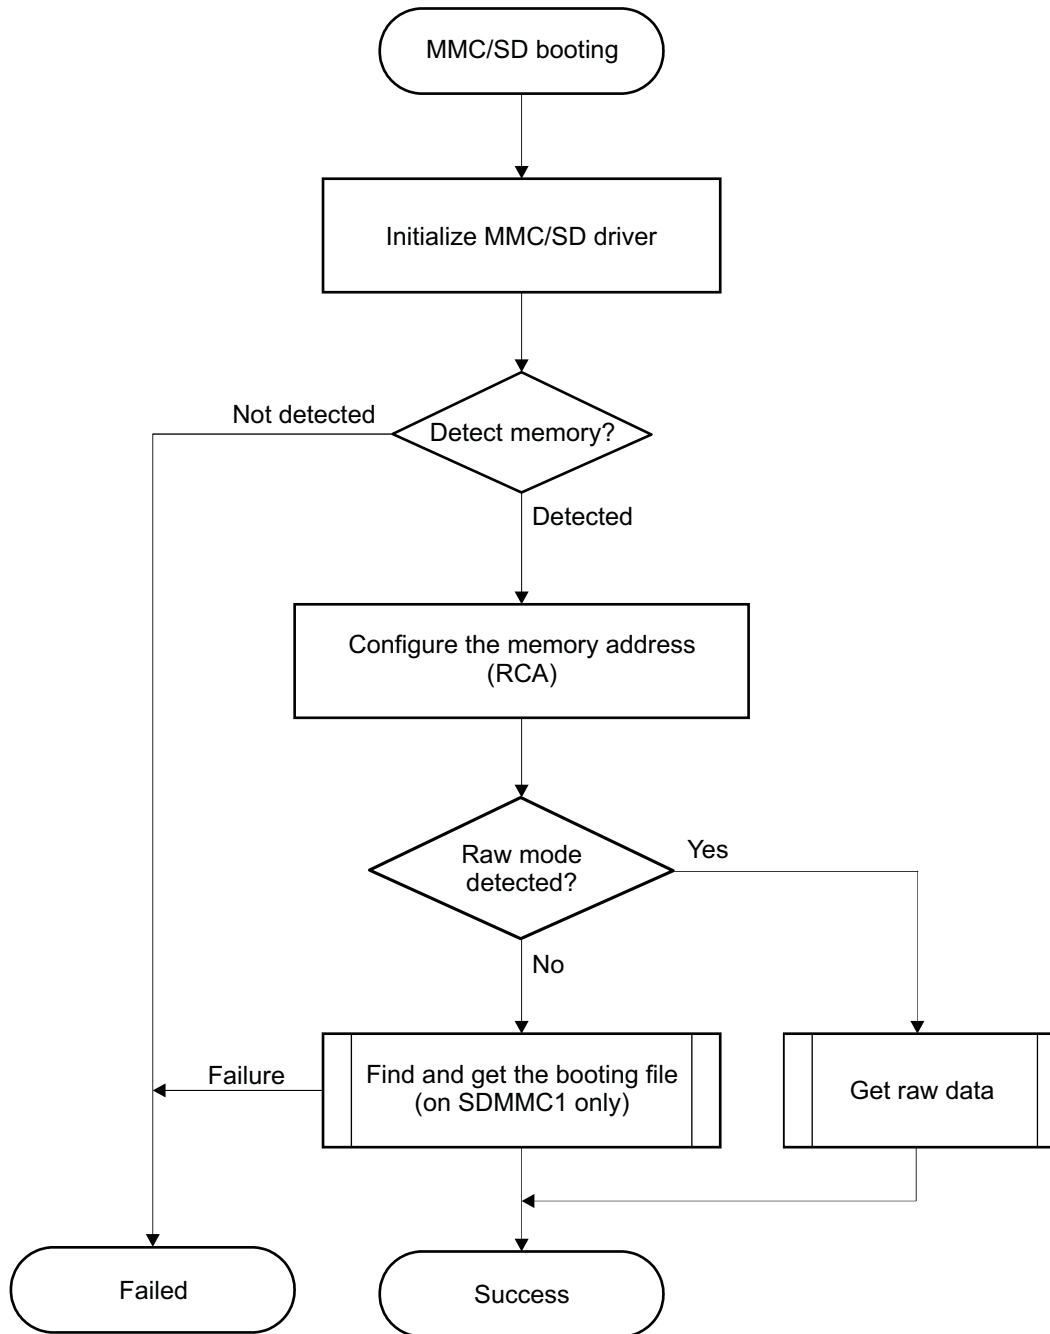

The OMAP device supports two booting modes:

- Raw: The booting image data is read directly from sectors in the user area.
- File system (FAT12/16/32 supported with or without master boot record): The image data is read from a booting file.

When using the SDMMC1 interface, raw and file system modes are supported. When using the SDMMC2 interface, only raw mode is supported. The purpose of this approach is to avoid the boot time penalty of searching for a file system hierarchy when it is not always necessary.

[Figure 27-27](#) shows the complete procedure.

Figure 27-27. eMMC/eSD and MMC/SD Booting

init-016

27.4.7.6.1 eMMC/eSD Overview

The ROM code supports eMMC/eSD cards, with the following conditions:

- eMMC devices compliant with *Embedded MultiMediaCard (eMMC) eMMC/Card Product Standard, High Capacity, including Reliable Write Boot, and Sleep Modes, Dual Data Rate, Multiple Partitions Supports and Security Enhancement v4.41* from the MMCA Technical Committee. The exception is the hardware reset feature. If the user software requires MMC hardware reset, it can be accomplished with a GPIO.
- eSD devices compliant with *SD Specification Part 1 eSD (Embedded SD) Specification Addendum v2.1)* from the SD Card Association

- The eMMC/eSD memory device is powered externally by a power-management IC or other power supply.
- Initial 1-bit MMC mode, optional 4-bit or 8-bit modes.
- Clock frequency:
 - Identification mode: 400 kHz
 - Data transfer mode: Up to 10 MHz, optionally up to 19.2 MHz
- Only one memory connected to the bus

27.4.7.6.1.1 System Conditions and Limitations

The ROM code does not support the specific details of the partition management and boot operations modes as defined in the eMMC Standard sections *Partition Management* and *Boot Operation Mode*. The booting image is assumed to be located in the User Data Area (no use of boot and/or RPMB partitions). Customers must set up the eMMC device appropriately so that the booting image is located in a reliable area within the User Data Area (possibly with the Enhanced User Data Area property).

The ROM code does not provide a bus direction control signaling in case of using MMC interface 2 with level shifters.

The ROM code expects that the eMMC device is powered externally and supplies are set and stable upon entering the booting procedure. The ROM code does not perform any software action to the companion device with respect to powering the eMMC/eSD device.

27.4.7.6.1.2 eMMC/eSD Memory Connection

An eMMC/eSD device typically requires two supplies: one for the core memory array (selectable 1.8/2.9 V at TWL6030 BOOT2 pin level) (see TWL6030 documentation), and one for the device interface I/Os and controller (typical VCCQ = 1.8 V). Both memory device supply pins can possibly be merged into one, thus requiring only one power supply.

The SD/MMC2 interface shares the same balls as the GPMC interface. Therefore, the ROM code performs the necessary pin mux configuration to route the MMC signal through the GPMC balls.

[Figure 27-28](#) shows an example of the system connection between the power-management IC, memory device, and OMAP device.

Figure 27-28. eMMC/eSD Connection

The ROM code supports the muxing of the MMC interface 2 through two paths:

- GPMC pins in configuration mode 1 (Mux1)
- SDMMC5/FREF_CLKx pins in Mux5

The ROM code performs the necessary I/O pin muxing configuration to route the MMC2 signals through the appropriate pins depending on the selected SYSBOOT configuration.

27.4.7.6.2 MMC/SD Overview

The ROM code supports booting from MMC/SD cards under the following conditions:

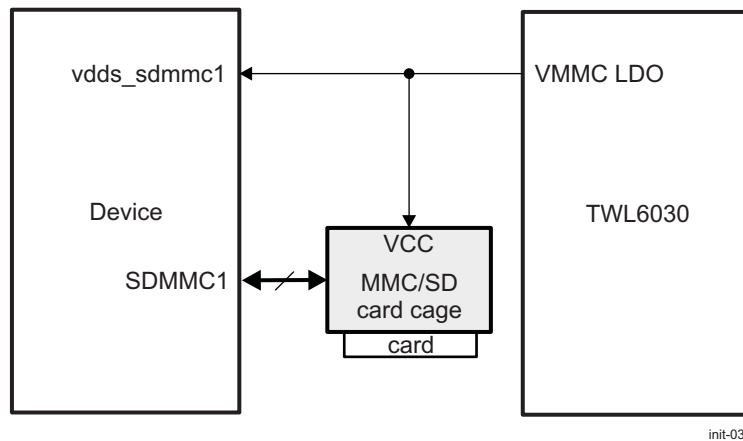

- MMC/SD cards compliant with *The MultiMediaCard System Specification* from the MMCA Technical Committee and the *SD Memory Card Specifications, File System Specification* from the SD Association. These Include low- and high-capacity cards
- MMC/SD cards connected to SDMMC interface 1
- 3-V VCC power supply, support for 3-V or 1.8-V I/O voltages
- Initial 1-bit MMC mode, optional 4-bit or 8-bit modes
- Clock frequency:
 - Identification mode: 400 kHz
 - Data transfer mode: Up to 10 MHz (optionally up to 19.2 MHz)
- Only one card connected to the bus

27.4.7.6.2.1 MMC/SD Card Connection

An SD/MMC card can be connected to the MMC1 interface, typically through a card cage. The ROM code sends the appropriate I²C sequence to the power-management IC to set the VMMC LDO to 3 V and switch it on.

Figure 27-29 shows the typical connection between the power IC, the card, and the OMAP device .

Figure 27-29. MMC/SD Card Connection

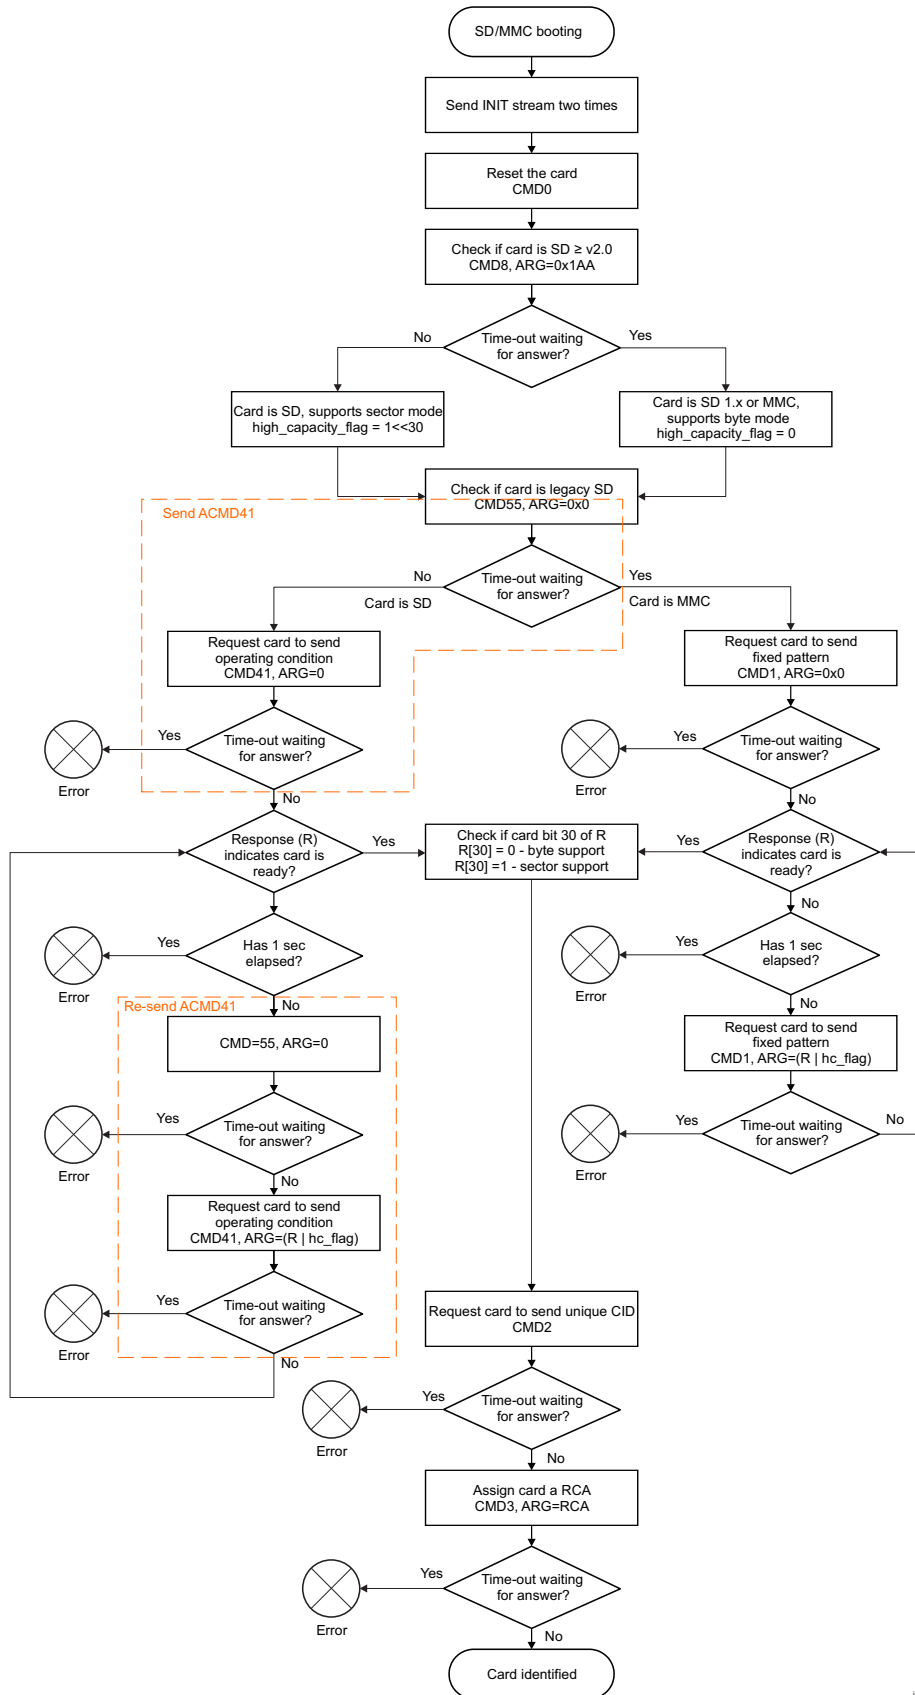

NOTE: The ROM code does not handle the card detection feature on the card cage.

27.4.7.6.3 Initialization and Detection

The ROM code initializes the memory device or card connected on the interface using the standard high-voltage range (3.0 V). If neither a card or memory device is detected, the ROM code moves on to the next booting device. The standard identification process and relative card address (RCA) assignment are used. However, the ROM code assumes that only one memory or card is connected on the bus. This is done using the CMD line common to the SD and MMC memory devices. The MMC and SD standards describe this phase as the initialization phase.

Figure 27-30 shows the MMC/SD detection procedure.

Figure 27-30. MMC/SD Detection Procedure

int-026

27.4.7.6.4 Read Sector Procedure

- Raw mode

In raw mode, an image can be located at one of the four consecutive locations in the main area: offset 0x0 (0KB)/0x20000 (128KB)/0x40000 (256KB)/0x60000 (384KB). For this reason, the size of a booting image must not exceed 128KB. However, a device with an image greater than 128KB can be flash starting at one of the aforementioned locations. Therefore, the ROM code does not check the image size. The only drawback is that the image crosses the subsequent image boundary. Raw mode is detected by reading sectors 0, 256, 512, and 768. The content of these sectors is verified for the presence of a TOC structure. For a GP device, a CH (if used) must be located in the first sector followed by a GP header. The CH can be void (containing only a CHSETTINGS item for which the Valid field is 0), as described in [Section 27.4.8.2, Configuration Header](#). Image data is read directly from continuous sectors of a card. If raw mode is not detected, file system mode is assumed.

- File system handling

File system support is available only for SDMMC1 interface. The sector read procedure uses the standard MMC/SD read data procedure. The sector address is generated based on the booting memory file map collected during initialization. Thus, the ROM code can freely address sectors in the booting file space.

27.4.7.6.5 File System Handling

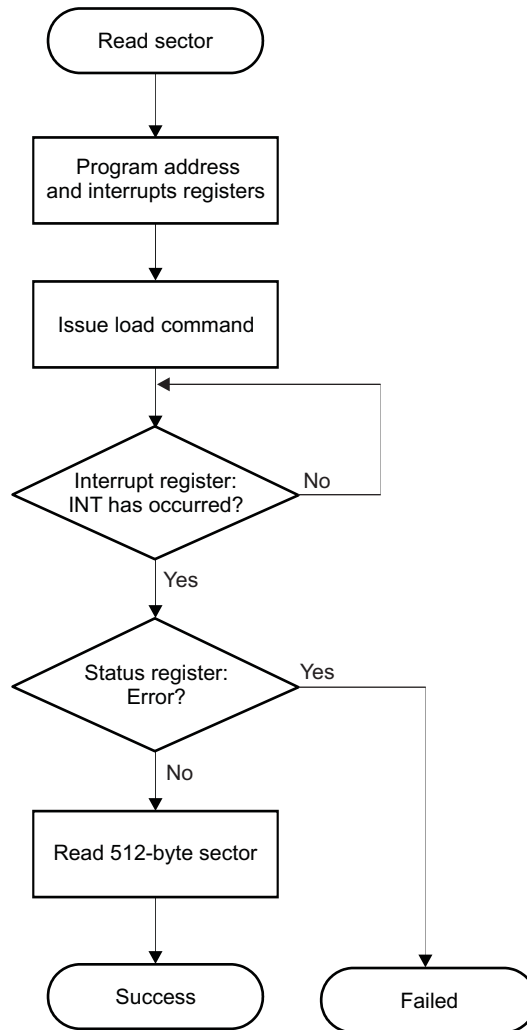

The MMC/SD cards can hold a file system that the ROM code reads. The image used by the booting procedure is taken from a booting file named MLO. This file must be in the root directory on an **active** primary partition of type FAT12/16 or FAT32.

An MMC/SD card can be configured as floppy-like or hard-drive-like:

- When acting like a floppy, the content of the card is a single FAT12/16/32 file system without an MBR holding a partition table.
- When acting like a hard drive, an MBR is present in the first sector of the card. This MBR holds a table of partitions, one of which must be FAT12/16/32, primary, and active.

According to the *MultiMediaCard FAT16 File System Specification* from the MMCA Technical Committee, the card must always hold an MBR, except for MMC cards using a floppy-like file system. However, depending on the operating system used, the MMC/SD card is formatted with or without partition(s) (using an MBR). The ROM code supports both types: floppy-like or hard-drive-like. The ROM code retrieves a map of the booting file from the FAT table. The booting file map is a collection of all FAT table entries related to the booting file (a FAT entry points to a cluster holding part of the file). The booting procedure uses this map to access any 512-byte sector in the booting file without involving the ROM code FAT module. [Figure 27-31](#) shows the complete process.

Figure 27-31. SD/MMC Get Booting File

init-025

27.4.7.6.5.1 MBR and FAT File System

This paragraph describes functions used by the ROM code to recognize whether an MBR with a FAT is used. It is not intended to fully describe the MBR and the FAT file system detection and reading procedure. The ROM code can detect FAT12/16/32 allocation table types. It cannot boot on devices with NTFS or Linux® FS partitions. Some memory devices that support file systems can be formatted with or without MBR; therefore, the first task of the ROM code is to detect whether the device is holding an MBR in the first sector.

The MBR is the first sector of a memory device. It consists of executable code, four partition entries, and one signature. The aim of such a structure is to divide the hard disk in partitions used primarily to boot different systems (for instance, Microsoft Windows™). This structure is described in [Table 27-42](#), and the partition table entry is described in [Table 27-43](#).

Table 27-42. Master Boot Record Structure

| Offset | Length (Bytes) | Entry Description |
|--------|----------------|-----------------------|
| 0000h | 446 | Optional code |
| 01BEh | 16 | Partition table entry |
| 01CEh | 16 | Partition table entry |
| 01DEh | 16 | Partition table entry |
| 01EEh | 16 | Partition table entry |
| 01FEh | 2 | Signature (0xAA55) |

Table 27-43. Partition Table Entry

| Offset | Length [Bytes] | Entry Description | Value |
|--------|----------------|----------------------------------------------------------|------------------------------------------------------------------------------------|
| 0000h | 1 | Partition state | 00h: Inactive 80h: Active |
| 0001h | 1 | Partition start head | Hs |
| 0002h | 2 | Partition start cylinder and sector | Cs[7:0]-Cs[9:8]-Ss[5:0] |
| 0004h | 1 | Partition type | 01h: FAT12 04h, 06h, 0Eh: FAT16 0Bh, 0Ch, 0Fh: FAT32 |
| 0005h | 16 | Partition end head | He |
| 0006h | 2 | Partition end cylinder and sector | Ce[7:0]-Ce[9:8]-Se[5:0] |
| 0008h | 4 | First sector position relative to the beginning of media | LBA _s = Cs.H.S+ Hs.S+ Ss-1 |
| 000Ch | 4 | Number of sectors in partition | LBA _e = Ce.H.S+ He.S+ Se-1 Nb s= LBA _e -LBA _s + 1 |

SD/MMC booting consists of the following steps:

Step 1. MBR detection

The ROM code first checks whether the MBR signature is present, and then it searches an active FAT12/16/32 partition in all four MBR partition entries, based on the type field. If the MBR entries are not valid, or if no usable partition is found, the ROM code returns to the booting procedure with FAIL. The extended partitions are not checked; the booting file must reside in a primary partition. Each partition entry is checked:

- (a) If its type is set to 00h, all fields in the entry must be 00h.
- (b) The partition is checked to be within physical boundaries (that is, the partition is inside and it fits the total physical sectors).

See [Figure 27-32](#) for more information about MBR detection.

Figure 27-32. MBR Detection Procedure

init-028

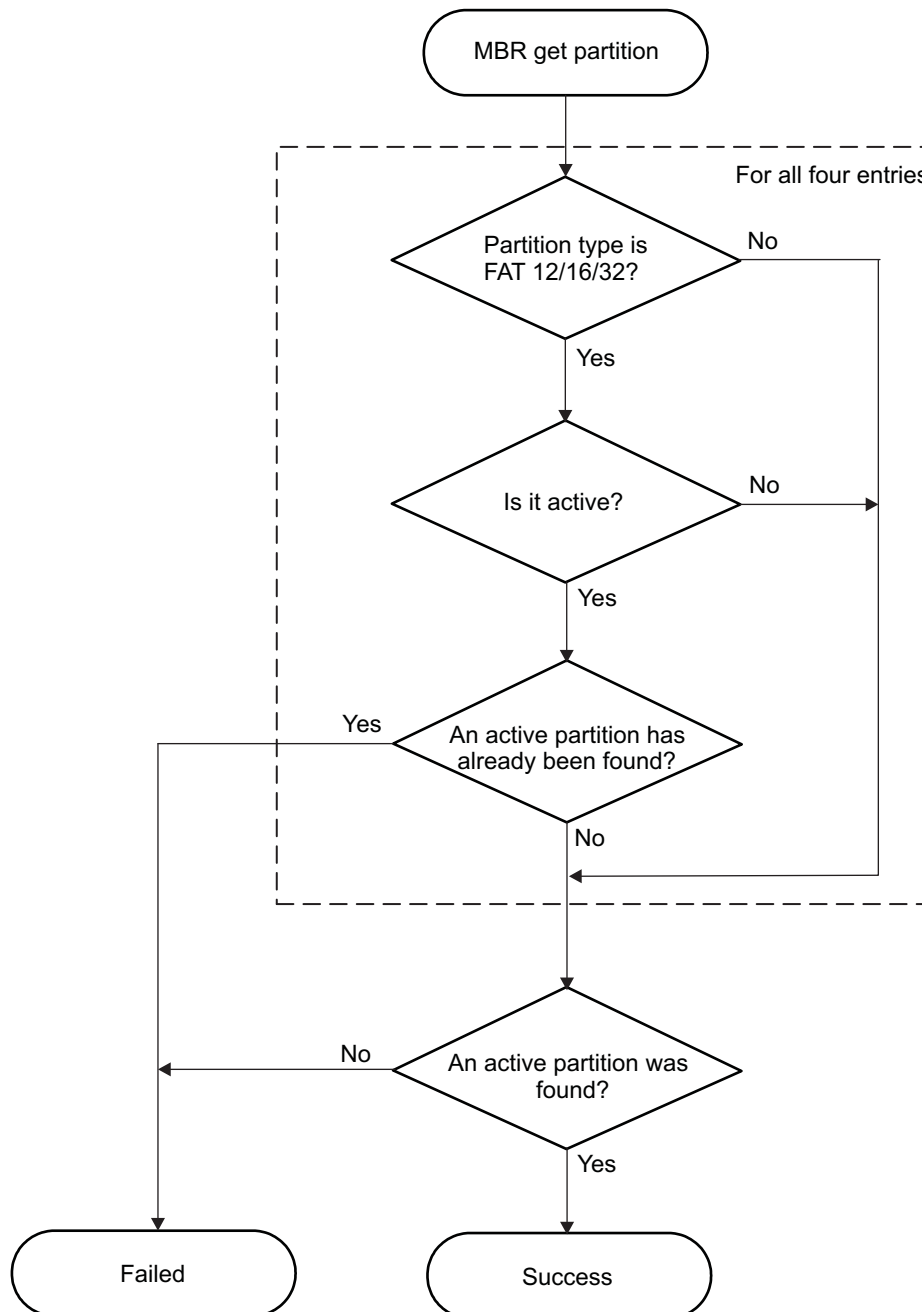

Step 2. Get the MBR partition.

Once identified, the ROM code gets the partition using the procedure described in Figure 27-32. The partition type is checked to be FAT12/16 or FAT32. Its state must be 00h (inactive) or 80h (active.) The ROM code returns with FAIL if no active primary FAT12/16/32 is found, or the test fails if there is more than one active partition. If an active partition is found, its first sector is read and used later. If no MBR is present (in case of a floppy-like system), the first sector of the device is read and used later. The read sector is checked to be a valid FAT12/16 or FAT32 partition. If this fails, the ROM code returns with FAIL if another partition type is used (for instance, Linux FS) or if the partition is not valid.

The FAT file system consists of several parts:

- Boot sector, which holds the BIOS parameter block (BPB). Not all are used by the ROM code.
- FAT, which describes the use of each cluster of the partition
- Data area, which holds the files, directories, and root directory (for FAT12/16, the root directory has a specific fixed location)

To check whether a sector holds a valid FAT12/16/32 partition, many fields of the boot sector (used by all FAT types) that must have specific values are checked. Figure 27-33 shows more about getting the partition.

Figure 27-33. MBR, Get Partition

init-029

Step 3. Find the booting file.

When a partition is found, the root directory entries are searched for a booting file named MLO in the root directory of the FAT12/16/32 file system. The file is not searched in any other location. For a FAT12/16 file system, the root directory has a fixed location, which is cluster 0. For a FAT32 file system, its cluster location is given by BPB_RootClus. The formula to find the sector number (relative to device sector 0, not partition sector 0) of a cluster is given by the following equation:

$$Cluster_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BPB_NumFATs \cdot BPB_FATSz + Cluster \cdot BPB_SecPerCLus$$

init-E001

NOTE: BPB_FatSz is BPB_FatSz16 for FAT12/16, or BPB_FatSz32 for FAT32.

NOTE: The BPB_HiddSec field can contain 0, even though the FAT file system is somewhere other than on sector 0 (floppy-like). The ROM code uses the partition offset taken from the MBR instead of this field, which can be wrong. If no MBR is found (floppy-like), the value 0 is used.

Each entry in the root directory is 32 bytes and holds information about the file (the filename, date of creation, rights, cluster location, etc.). (See [Table 27-44](#).)

Table 27-44. FAT Directory Entry

| Offset | Length [Bytes] | Name | Description |
|--------|----------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0000h | 11 | DIR_Name | Short Name (8 + 3) |
| 000Bh | 1 | DIR_Attr | File Attributes: 01h - ATTR_READ_ONLY 02h - ATTR_HIDDEN 04h - ATTR_SYSTEM 08h - ATTR_VOLUME_ID 10h - ATTR_DIRECTORY 20h - ATTR_ARCHIVE 0Fh - ATTR_LONG_NAME |
| 000Ch | 1 | DIR_NTRes | Reserved. Set to 00h |
| 000Dh | 1 | DIR_CrtTimeTenth | Millisecond stamp at file creation |
| 000Eh | 2 | DIR_CrtTime | Time file was created. |
| 0010h | 2 | DIR_CrtDate | Date file was created. |
| 0012h | 2 | DIR_LstAccDate | Last access date |
| 0014h | 2 | DIR_FstClusHi | High word of the first cluster number of this entry |
| 0016h | 2 | DIR_WrtTime | Time of last write |
| 0018h | 2 | DIR_WrtDate | Date of last write |
| 001Ah | 2 | DIR_FstClusLo | Low word of the first cluster number of this entry |
| 001Ch | 4 | DIR_FileSize | File size in bytes |

The ROM code checks each entry in the root directory until either the booting file is found or the entry is empty (first byte is 00h), or when the end of the root directory is reached. Entries with the ATTR_LONG_NAME attribute (LFN) and first byte at E5h (erased file) are ignored. When found, the first cluster offset of the file is read from the DIR_FstClusHi/DIR_FstClusLo fields. There is a slight difference between FAT12/16 and FAT32 when handling the root directory. On FAT12/16, this directory has a fixed location (see above) and length fixed by BPB_RootEntCnt, which is the total of 32-byte entries. Handling this directory is therefore straightforward. On FAT32, the root directory is like a standard file. The FAT must be used to retrieve each sector of the directory. The way in which the FAT is handled is described in the following paragraph.

Step 4. Buffer FAT entries in the FAT buffer

When the booting file is found, the ROM code reads the FAT and buffers the singly-linked chain of clusters in a FAT buffer used by booting to access the file directly, sector by sector. For FAT12/16 and for FAT32, multiple copies of the FAT exist (ROM code supports only two copies), after the boot sector.

$$FATn_{sector} = BPB_HiddSec + BPB_RsvdSecCnt + BP_FatSz \cdot n$$

init-E002

The size of the FAT buffer is given by BPB_FATSz16 or BPB_FATSz32. The ROM code checks each copy of the FAT if they are identical. If the values are different, the ROM code uses the value from the last FAT copy. With the FAT32 file system, the copy system can be disabled according to a flag in BPB_ExtFlags[7]. If this flag is set, the FAT BPB_ExtFlags[3:0] bit field is used. In this case, no verification is made by the ROM code with other copies of FAT.

The FAT is a simple array of values, each referring to a cluster located in the data area. One entry of the array is 12, 16, or 32 bits, depending on the file system in use. The value in an entry defines

whether the cluster is being used or not, and if another cluster must be considered. This creates a singly-linked chain of clusters defining the file. The meaning of an entry is described in [Table 27-45](#).

NOTE: For compatibility, cluster 0 and cluster 1 are not used for files, and these entries must contain:

- FF8h and FFFh (for FAT12)
- FFF8h and FFFFh (for FAT16)
- 0FFFFFFF8h and 0FFFFFFFh (for FAT32)

Table 27-45. FAT Entry Description

| FAT12 | FAT16 | FAT32 | Description |
|-----------|-----------------|---------------------------|--------------------------------------------|
| 000h | 0000h | 00000000h | Free cluster |
| 001h | 0001h | 00000001h | Reserved cluster |
| 002h-FEFh | 0002h- FFEFh | 00000002h- 0FFFFFFEFh | Used cluster; value points to next cluster |
| FF0h-FF6h | FFF0h- FFF6h | 0FFFFFFF0h- 0FFFFFFF6h | Reserved values |
| FF7h | FFF7h | 0FFFFFFF7h | Bad cluster |
| FF8h-FFFh | FFF8h- FFFh | 0FFFFFFF8h- 0FFFFFFFh | Last cluster in file |

NOTE: FAT32 uses only bits [27:0]; the upper 4 bits are usually 0 and must be left untouched.

When accessing the root directory for FAT32, the ROM code starts from the root directory cluster entry and follows the linked chain to retrieve the clusters.

When the booting file has been found, the ROM code buffers each FAT entry corresponding to the file in a sector way. This means each cluster is translated to one or several sectors, depending on how many sectors are in a cluster (BPB_SecPerClus). This buffer is used later by the booting procedure to access the file.

27.4.7.7 LPDDR2-NVM

The OMAP device allows booting from a LPDDR2-NVM device connected to the EMIF interface. After setup, the NVM device can be accessed in XIP mode and instructions fetched directly through the EMIF interface (similarly as the XIP/NOR-like interfaces described in [Section 27.4.7.3, XIP Memory](#)).

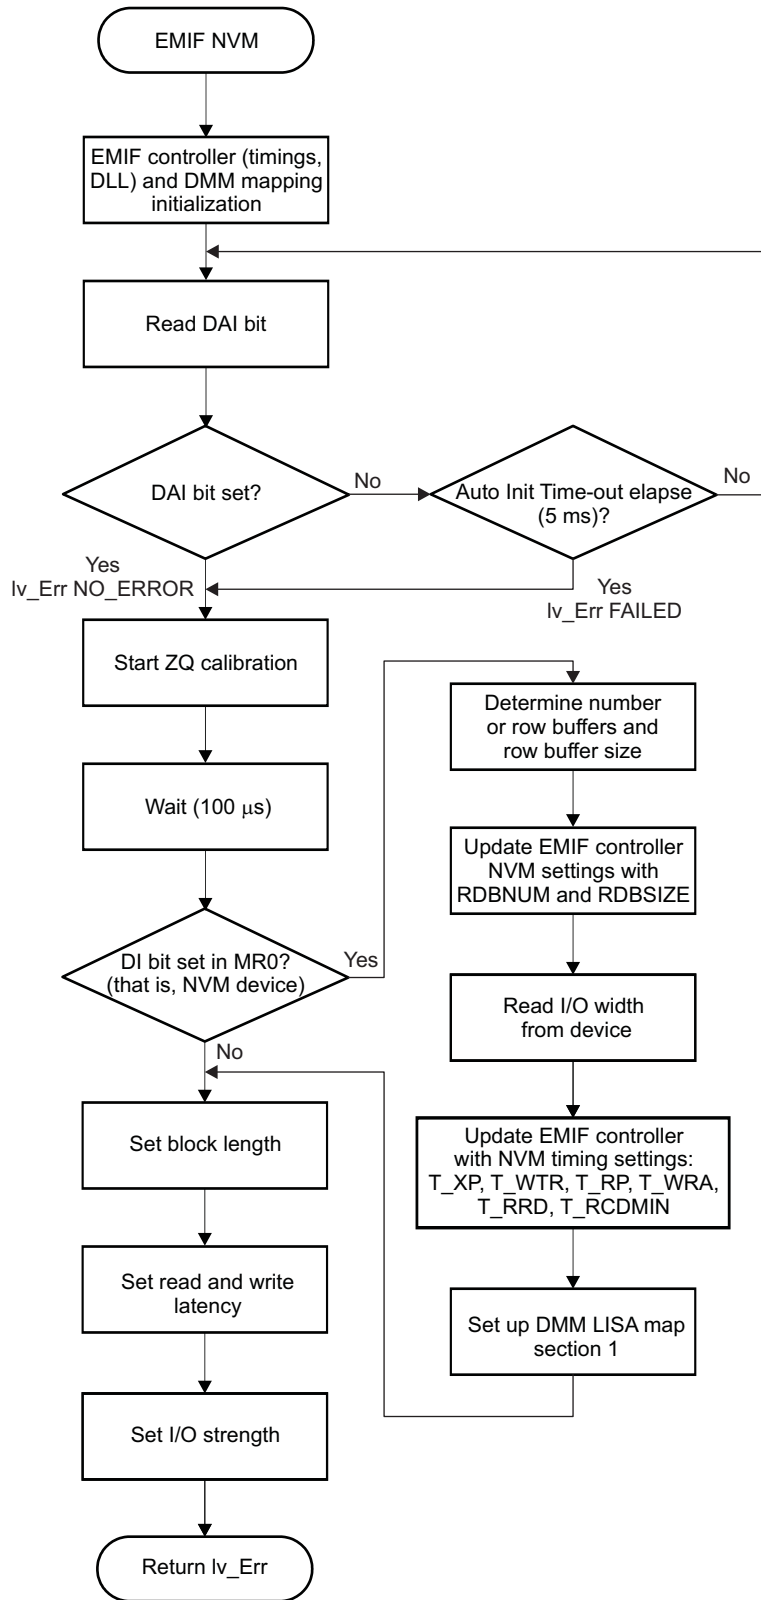

Features:

- XIP addressable
- Uses EMIF as the communication interface
- Up to 2-GB memories can be connected
- x32 data bus width only
- Supports 4/8 row data buffers of 32/64 bytes
- EMIF DDR clock frequency at boot time is 50 MHz
- Device connected to EMIF1/CS1, mapped at address C000000h

27.4.7.7.1 Initialization and Detection

[Figure 27-26](#) shows the initialization and detection procedure.

Figure 27-34. EMIF LPDDR2-NVM Detection and Initialization

init-043

The ROM code first performs basic initialization of the EMIF controller and prepares for communication through EMIF1/CS1. The clock frequency at device boundary (ck pin) has been setup during the clocks setup (see [Section 27.4.4.2, Clocking Configuration](#)) to be 50 MHz (as defined as the upper boundary of the JEDEC specification for boot).

The device auto-initialization (DAI) status bit in Mode Register 0 (MR0) is polled for completion of device auto-initialization. This must complete within a 5-ms timeframe. If not, the initialization procedure returns with FAIL and the ROM code moves to the next device in the booting list. The MR0 device information (DI) bit reflects whether the attached device is an NVM device.

Then, the ROM code sends a ZQ calibration command (mode register write to MR10) and waits for completion (simple wait for 100 μ s). If the DI bit is set (it has been detected during the auto-initialization sequence), the ROM code determines the number and size of row data buffers and sets up the EMIF controller accordingly. Additionally, the NVM registers of the EMIF controller are updated with appropriate NVM timings.

The DMM (LISA map section 1) is set up to open a 2-GB window from system address C0000000h. This leaves the possibility for using a CHRAM configuration header to enable further SDRAM access.

The last steps consist in sending three configuration commands for:

- Block length setup, burst sequence, wrapping, and nWR (MR1)
- Read/write latency (MR2)
- I/O strength (MR3)

[Table 27-46](#) summarizes the list of mode registers used during NVM device configuration.

Table 27-46. Summary of Mode Register Commands

| Mode Register (JEDEC Name) | Read/Write | Use |
|----------------------------|------------|---------------------------------------------------------------------------------------------------|
| MR0 (Device_info) | MRR | Polling for auto-initialization and NVM device type determination |
| MR1 (Device_Feature1) | MRW | Block length setup (BL = 8), sequential burst (default), wrap enable (default), nWR = 3 (default) |
| MR2 (Device_Feature2) | MRW | Read/Write latency (RL = 3 / WL = 1, default) |
| MR3 (IO_Config1) | MRW | I/O strength (40 Ω , default) |
| MR8 (Basic_Config4) | MRR | I/O width determination (not used currently) ⁽¹⁾ |
| MR10 (IO_Calibration) | MRW | ZQ calibration (FFh, calibration command after initialization) |
| MR20 (NVM_Geometry) | MRR | Determination of number and size of row data buffers |

⁽¹⁾ The MR8 register is read for I/O width determination; however, no specific action is performed with this information. The device is assumed to be 32 bits wide.

27.4.8 Image Format

27.4.8.1 Overview

An image has two major parts:

- An optional configuration header (CH)
- Software to execute

The CH can contain several parameters set by users to speed up booting. It is further described in [Section 27.4.8.2, Configuration Header](#).

The second part contains the software that is loaded into the memory and executed.

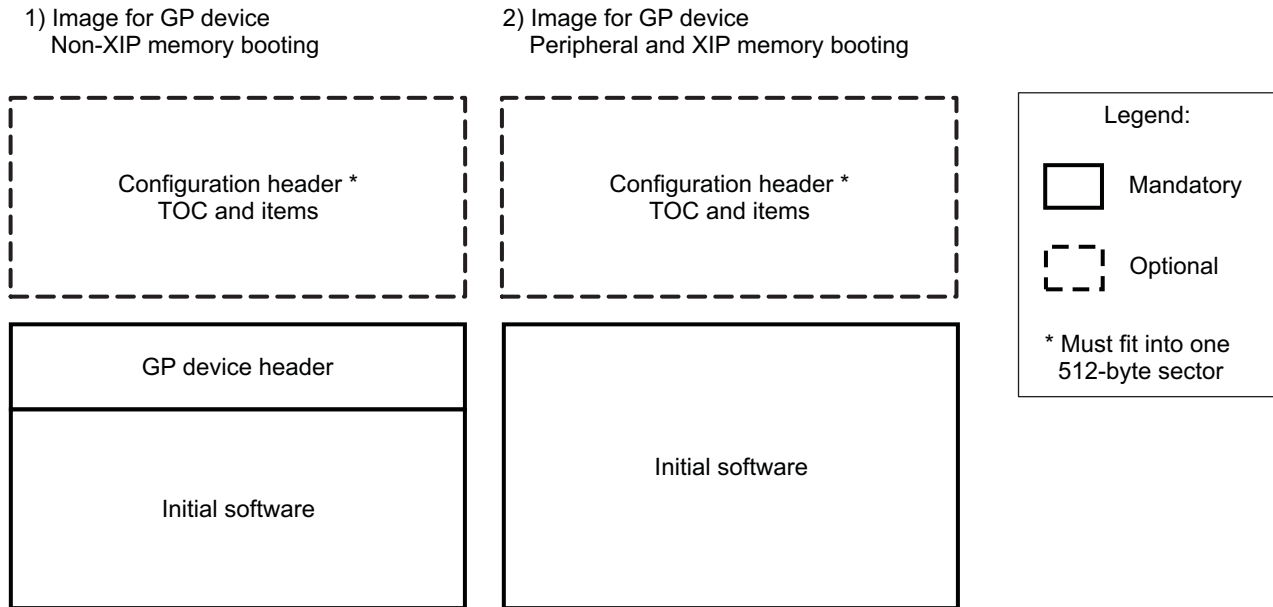

[Figure 27-35](#) is an overview of the boot image formats. There are two image types:

1. GP non-XIP memory booting: This image type is used for memories that require shadowing (for example, MMC). An image can contain a CH that includes at least a CHSETTINGS item entry. Next, there must be a small header (referred to as a GP header) that contains information about the size and

the destination address.

- When the memory device is of XIP type (for example, NOR), the GP header is not required, and the image can contain code for direct execution. Optionally, the first sector can contain a CH. The same image format is used for peripheral booting (where the code is transferred to internal RAM).

Figure 27-35. Image Formats

init-018

27.4.8.2 Configuration Header

The ROM code default settings (such as clock frequencies, EMIF, GPMC, or MMCHS interfaces) can be tuned by the user by using the CH.

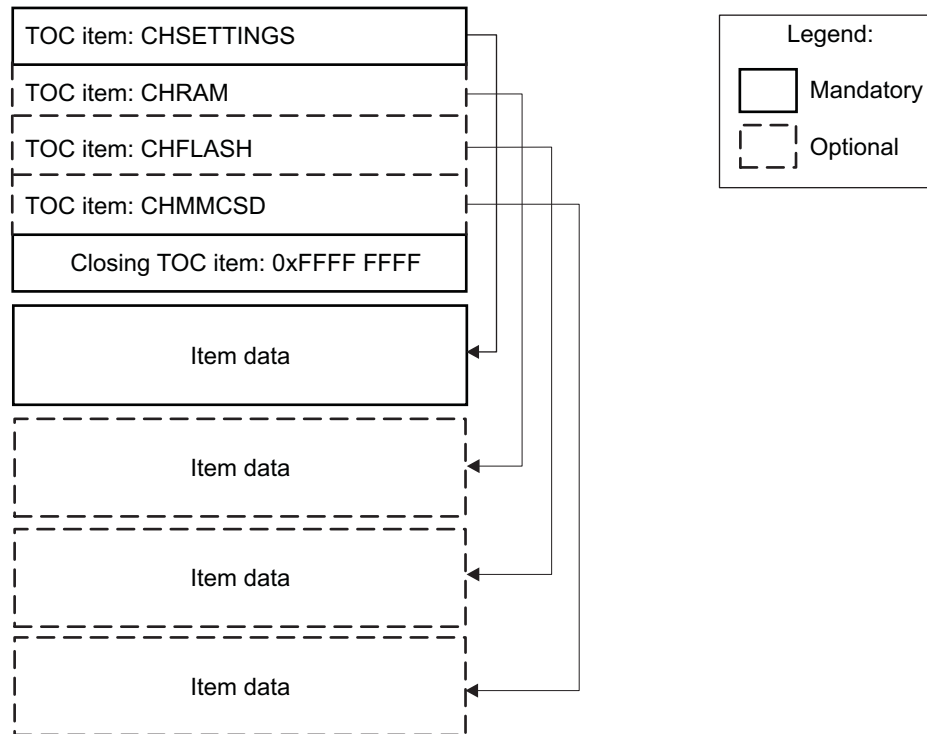

The CH can contain the following parts:

- Settings: Various clock settings (mandatory)
- RAM: EMIF settings
- FLASH: Flash interface (GPMC) settings
- MMC/SD: MMCHS interface settings

The beginning of the CH is a table of contents (TOC), which points to each item. This is described in [Figure 27-36](#). Each TOC item is a simple structure described in [Table 27-47](#). The complete CH (CH TOC and items) should fit in a 512-byte sector.

The ROM code identifies the presence of a CH by reading the first TOC item if it contains a known string (CHSETTINGS, CHRAM, etc.). Next, the TOC is identified and searched until a 0xFFFFFFFF offset is found. The CH is read and parameters are executed sequentially.

For the sake of simplicity, each field represents the content of a register to be modified. Only fields required for the configuration are used; fields for status, for instance, are not modified and therefore are not shown in the tables.

Figure 27-36. CH Format

init-019

Table 27-47. CH TOC Item

| Offset | Field | Size (Bytes) | Description |
|--------|----------|--------------|---------------------------------------------------------------------------------|
| 0x0000 | Start | 4 | Offset from the start address of the TOC to the actual address of item contents |
| 0x0004 | Size | 4 | Size of item |
| 0x0008 | Reserved | 4 | Unused |
| 0x000C | Reserved | 4 | Unused |
| 0x0010 | Reserved | 4 | Unused |
| 0x0014 | Filename | 12 | 12-character name of a item, including the zero (0) termination character |

27.4.8.2.1 CHSETTINGS Item

The CHSETTINGS configuration header contains settings specific to the clock system. The ROM code configures the OMAP clocking to some default settings as described in [Section 27.4.4.2, Clocking Configuration](#). The CH CHSETTINGS section contains a method to override the ROM code default clock settings.

[Table 27-48](#) describes the fields. The clocking procedure and the clocking setting structure are described in [Section 27.4.4.4, Software Booting Configuration](#).

Table 27-48. CHSETTINGS Item

| Offset | Field | Description |
|--------|-------------|----------------------------------------------|
| 0000h | Section key | Key used for item verification: C0C0C0C1h |
| 0004h | Valid | Enables/disables the section 00h: Disable |

Table 27-48. CHSETTINGS Item (continued)

| Offset | Field | Description |
|--------|-------------------|-------------------------------------------------------------------------|
| | | Others: Enable |
| 0005h | Version | Configuration header version 01h Others: Reserved |
| 0006h | Reserved | |
| 0008h | Clocking settings | Described in Table 27-16 starting from the FLAGS field. |

27.4.8.2.2 CHRAM Item

The CHRAM configuration header contains settings specific to the SDRAM memory controller (EMIF). [Table 27-49](#) describes the fields. The ROM code does not configure the EMIF by default, because it cannot assume any external SDRAM type. Therefore, if the ROM code is needed to configure the SDRAM access, the user must provide the appropriate timing details in the CHRAM structure. For more information, see [Section 15.3, EMIF Controller](#), and [Section 15.3.6, EMIF Register Manual](#).

Table 27-49. CHRAM Item

| Offset | Field | Description |
|--------|----------------------|----------------------------------------------------------------------------------------------------------------------|
| 0000h | Section key | Key used for section verification: C0C0C0C2h. |
| 0004h | Valid | Enables/disables the section: 00h: Disable Other: Enable |
| 0005h | Reserved | |
| 0008h | SdramConfig (EMIF1) | SDRAM configuration register (EMIF1.EMIF_SDRAM_CONFIG) |
| 000Ch | SdramRefresh (EMIF1) | SDRAM Refresh control register (EMIF1.EMIF_SDRAM_REF_CTRL) |
| 0010h | SdramTim1 (EMIF1) | SDRAM timing 1 register (EMIF1.EMIF_SDRAM_TIM_1) |
| 0014h | SdramTim2 (EMIF1) | SDRAM timing 2 register (EMIF1.EMIF_SDRAM_TIM_2) |
| 0018h | SdramTim3 (EMIF1) | SDRAM timing 3 register (EMIF1.EMIF_SDRAM_TIM_3) |
| 001Ch | PwrMgtCtrl (EMIF1) | Power-management control register (EMIF1.EMIF_PWR_MGMT_CTRL) |
| 0020h | DdrPhyCtrl1 (EMIF1) | DDR PHY control 1 register (EMIF1.EMIF_DDR_PHY_CTRL_1) |
| 0024h | DdrPhyCtrl2 (EMIF1) | DDR PHY control 2 register (EMIF1.EMIF_DDR_PHY_CTRL_2) |
| 0028h | ModeReg1 (EMIF1) | Mode register MR1 (in the LPDDR2 device) |
| 0029h | ModeReg2 (EMIF1) | Mode register MR2 (in the LPDDR2 device) |
| 002Ah | ModeReg3 (EMIF1) | Mode register MR3 (in the LPDDR2 device) |
| 002Bh | Reserved | |
| 002Ch | SdramConfig (EMIF2) | SDRAM configuration register (EMIF2.EMIF_SDRAM_CONFIG) |
| 0030h | SdramRefresh (EMIF2) | SDRAM refresh control register (EMIF2.EMIF_SDRAM_REF_CTRL) |
| 0034h | SdramTim1 (EMIF2) | SDRAM timing 1 register (EMIF2.EMIF_SDRAM_TIM_1) |
| 0038h | SdramTim2 (EMIF2) | SDRAM timing 2 register (EMIF2.EMIF_SDRAM_TIM_2) |
| 003Ch | SdramTim3 (EMIF2) | SDRAM timing 3 register (EMIF2.EMIF_SDRAM_TIM_3) |
| 0040h | PwrMgtCtrl (EMIF2) | Power-management control register (EMIF2.EMIF_PWR_MGMT_CTRL) |
| 0044h | DdrPhyCtrl1 (EMIF2) | DDR PHY control 1 register (EMIF2.EMIF_DDR_PHY_CTRL_1) |
| 0048h | DdrPhyCtrl2 (EMIF2) | DDR PHY control 2 register (EMIF2.EMIF_DDR_PHY_CTRL_2) |
| 004Ch | ModeReg1 (EMIF2) | Mode register MR1 (in the LPDDR2 device) |
| 004Dh | ModeReg2 (EMIF2) | Mode register MR2 (in the LPDDR2 device) |
| 004Eh | ModeReg3 (EMIF2) | Mode register MR3 (in the LPDDR2 device) |
| 004Fh | Reserved | |
| 0050h | DMM LISA Map 0 | DMM LISA section 0 mapping (see Section 15.2 for more information about the DMM module architecture) |

Table 27-49. CHRAM Item (continued)

| Offset | Field | Description |
|--------|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0054h | Flags | Setting bits 0 to 3 requests ROM code to configure the appropriate channel/chip select: Bit[0]: Configure EMIF1 CS0 Bit[1]: Configure EMIF1 CS1 Bit[2]: Configure EMIF2 CS0 Bit[3]: Configure EMIF2 CS1 Other bits: Reserved |

NOTE:

- The ROM code supports only the LPDDR2 memory type (as set in the SDRAM configuration register).
- It is assumed that the same kind of SDRAM (same type and timings) is attached to both CSs when requesting the configuration of both CSs for a given EMIF (for example, if bit 0 and 1 of the flags field are set, it is assumed that both EMIF1 CSs are attached to the same kind of memory).

27.4.8.2.3 CHFLASH Item

The CHFLASH configuration header contains settings specific to the general-purpose memory controller (GPMC). For more information, see [Section 15.4, GPMC Overview](#). [Table 27-50](#) describes the fields.

Table 27-50. CHFLASH Item

| Offset | Field | Description |
|--------|-----------------------------|-----------------------------------------------------------------|
| 0000h | Section Key | Key used for section verification: C0C0C0C3h. |
| 0004h | Valid | Enables/disables the section: 00h: Disable Others: Enable |
| 0005h | Reserved | |
| 0008h | GPMC_SYSCONFIG (LSB) | Register values |
| 000Ah | GPMC_IRQENABLE (LSB) | |
| 000Ch | GPMC_TIMEOUT_CONTROL (LSB) | |
| 000Eh | GPMC_CONFIG (LSB) | |
| 0010h | GPMC_CONFIG1_0 | |
| 0014h | GPMC_CONFIG2_0 | |
| 0018h | GPMC_CONFIG3_0 | |
| 001Ch | GPMC_CONFIG4_0 | |
| 0020h | GPMC_CONFIG5_0 | |
| 0024h | GPMC_CONFIG6_0 | |
| 0028h | GPMC_CONFIG7_0 | |
| 002Ch | GPMC_PREFETCH_CONFIG1 | |
| 0030h | GPMC_PREFETCH_CONFIG2 (LSB) | |
| 0032h | GPMC_PREFETCH_CONTROL (LSB) | |
| 0034h | GPMC_ECC_CONFIG | |
| 0036h | GPMC_ECC_CONTROL | |
| 0038h | GPMC_ECC_SIZE_CONFIG (LSB) | |
| 003Ch | Enable_A1_A10 | 0: Do not change A1– A10 pads Others: Enable A1 – A10 pads |

27.4.8.2.4 CHMMCS D Item

The CHMMCS D configuration header contains settings specific to the high-speed MMC/SD/SDIO host controller (MMCHS). For more information, see [Chapter 24, MMC/SD/SDIO](#). [Table 27-51](#) describes the fields.

Table 27-51. CHMMCS D Item

| Offset | Register Modified | Description |
|--------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| 0000h | Section key | Key used for section verification C0C0C0C4h |
| 0004h | Valid | Enables/disables the section 00h: Disable Other: Enable |
| 0005h | Reserved | |
| 0008h | MMCHS_SYSCTRL(MSW) | Update MMCHS SYSCTRL interface register with the value specified in these fields. The register is not updated if the value is 0xFFFFFFFF. |
| 000Ah | MMCHS_SYSCTRL(LSW) | |
| 000Ch | MMCHS interface bus width | 1: 1 bit 2: 4 bits 4: 8 bits 0xFFFF FFFF: Do not update bus width. Others: Reserved |

The ROM code provides a booting parameter structure to the Initial software (see [Section 27.4.8.4, Image Execution](#)). This structure contains a field that indicates whether the configuration header items have been correctly processed. For a CHMMCS D item, if the MMCHS_SYSCTRL and bus width fields are set to 0xFFFF FFFF, the booting parameters report that the CHMMCS D section has not been executed, regardless of the value of the Valid field.

27.4.8.3 GP Header

When the booting memory device is non-XIP (for example, MMC) the image must contain a small header, located before the executable code, and having the size of the software to load and the destination address of where to store it. [Table 27-52](#) describes the image format. The GP header is not required when booting from an XIP memory device (for example, NOR) or in case of peripheral booting. In this case, the peripheral or memory booting image starts directly with executable code.

Table 27-52. GP Header Format

| Field | Non-XIP Device Offset | XIP Device Offset | Size (Bytes) | Description |
|-------------|-----------------------|-------------------|--------------|------------------------------------------------------|
| Size | 0x0000 | - | 4 | Size of the image |
| Destination | 0x0004 | - | 4 | Address where to store the image or code entry point |
| Image | 0x0008 | 0x0000 | x | Executable code |

NOTE: The destination address field stands for:

- Target address for the image copy from the non-XIP storage to the target XIP location (for example, internal RAM or SDRAM)
- Entry point for image code

Users must take care to locate the code entry point to the target address for image copy.

27.4.8.4 Image Execution

The image is executed at the time the ROM code performs the branch to the first executable instruction in the initial software. For a GP device in non-XIP, the execution address is the first word after the GP header. The branch is performed in public ARM supervisor mode. The R0 register points to the booting parameter structure that contains information about booting execution. [Table 27-53](#) shows the booting parameter structure.

Table 27-53. Booting Parameter Structure

| Offset | Field | Size (Bytes) | Description |
|--------|----------------------------------|--------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0x00 | Booting message | 4 | Last received booting message |
| 0x04 | Memory booting device descriptor | 4 | Pointer to a descriptor of the memory that has been used during the booting process. The pointer and the descriptor are required when user software uses the ROM code built-in API functions for that memory device. |
| 0x08 | Current booting device | 1 | Code of device used for booting: 0x00: void, no device 0x02: XIP memory 0x02: XIPWAIT memory (wait-signal monitoring on) 0x03: NAND 0x04: OneNAND 0x05: MMC1 0x06: MMC2(1) 0x07: MMC2(2) 0x08: EMIF 0x43: UART3 0x45: USB (internal transceiver) 0x46: USB-ULPI Others: Reserved |
| 0x09 | Reset reason | 1 | Current reset reason bit mask (bit = 1, event present): [0]: Power-on reset [1]: Global software warm reset [2]: Reserved [3]: MPU watchdog or WDTIMER2 reset [4]: Reserved [5]: External warm reset [6]: VDD MPU voltage manager reset [7]: VDD IVA voltage manager reset This is a direct copy of the lowest byte in the PRM_RSTST register. |
| 0x0A | CH flags | 1 | Configuration header items flag. Each item is described by 1 bit. A set bit indicates that the item was executed: [0]: CHSETTINGS [1]: CHRAM [2]: CHFLASH [3]: CHMMCS Other bits: Reserved |

27.4.9 Tracing

Tracing in the public ROM code consists in three 32-bit vectors for which each bit corresponds to a particular way point in the ROM code execution sequence. [Table 27-54](#) through [Table 27-56](#) list the organization of the tracing data in RAM. Tracing vectors are initialized at the beginning of the start-up phase and are updated all along the boot process.

There are two sets of tracing vectors ([Table 27-13](#)). The first set is the current trace information (after cold or warm reset). The second set holds a copy of trace vectors collected at the first ROM code run after cold reset. As a result, after a warm reset it is possible to have visibility on the boot scenario that occurred during cold reset.

[Table 27-54](#) lists the organization of tracing vector 1.

Table 27-54. Tracing Vector 1

| Bit | Group | Meaning |
|-----|--------------------------------|--------------------------------------------------|
| 0 | General | Passed the public reset vector |
| 1 | General | Entered main function |
| 2 | General | Running after the cold reset |
| 3 | Boot | Main booting routine entered |
| 4 | Memory boot | Memory booting started |
| 5 | Peripheral boot | Peripheral booting started |
| 6 | Boot | Booting loop reached last device |
| 7 | Boot | GP header (non-XIP) found |
| 8 | Boot | Booting message Skip peripheral booting received |
| 9 | Boot | Booting message Change device received |
| 10 | Peripheral boot | Booting message Peripheral booting received |
| 11 | Peripheral boot | Booting message Get ASIC ID received |
| 12 | Peripheral boot | Device initialized |
| 13 | Peripheral boot | ASIC ID sent |
| 14 | Peripheral boot | Image received |

27.5 Services for HLOS Support

The ROM code provides different services that can be called on GP devices for L2 cache maintenance, wake up of slave CPU(s), etc. These services are implemented in monitor mode (the service must be called by writing the function ID into the R12 register and using the SMC instruction) and do not use any resources like RAM/stack or hardware outside the master CPU. The caller must ensure the save and restore of the processor registers before and after calling the monitor service.

The following code example shows how the monitor ROM code functions can be accessed by an application running in public mode:

```

;----- ;
FUNCTION: PL310_SetDebugL2Cache
;
; DESCRIPTION: Function calls the Monitor Service to configure the debug
;               control register of the L2 cache.
;
; INPUTS: r0 Value to set in the debug control register
;
; RETURN:
;
;-----
PL310_SetDebugL2Cache FUNCTION
    PUSH {R1-R12, LR}
    LDR R12, =API_MONITOR_L2CACHE_SETDEBUG_INDEX
    SMC 0x1 POP {R1-R12, PC}
    ENDFUNC

```

27.5.1 L2 Cache Maintenance

Table 27-57. L2 Cache Write Debug Register

| Function ID | Description | |
|-------------|--------------------------------------------------------------|-----------------------------|
| R12 = 0x100 | Set the input parameter value in the L2 Cache Debug register | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Debug register value to set |
| Output | | |
| Return | | |

Table 27-58. L2 Cache Clean and Invalidate Range of Physical Address

| Function ID | Description | |
|-------------|-----------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| R12 = 0x101 | This function cleans and invalidates a range Physical Addresses. This is a workaround of the clean and invalidate L2 cache. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | Physical Start Address of the range Size of the range to invalidate |
| Output | | |
| Return | | |

Table 27-59. Enable/Disable L2 Cache

| Function ID | Description |
|-------------|--------------------------------------------------------------------------------------------|
| R12 = 0x102 | This function sets the given input value in the L2 Cache Control Register (enable/disable) |
| Parameters | |

Table 27-59. Enable/Disable L2 Cache (continued)

| Function ID | Description | |
|-------------|-------------|-------------------------------|
| Type | Location | Description |
| Input | R0 | Control register value to set |
| Output | | |
| Return | | |

Table 27-60. Write Auxiliary Control Register

| Function ID | Description | |
|-------------|---------------------------------------------------------------------------------------------|------------------------------|
| R12 = 0x109 | This function writes the PL310 Auxiliary Control Register with the input given value in R0. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to set in the register |
| Output | | |
| Return | | |

Table 27-61. Write Tag and Data RAM Latency Control Register

| Function ID | Description | |
|-------------|-------------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| R12 = 0x112 | This function writes the PL310 Tag and Data RAM Latency Control Register with the input given value in R0 and R1. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | Tag RAM latency to set Data RAM latency to set |
| Output | | |
| Return | | |

Table 27-62. Write Prefetch Control Register

| Function ID | Description | |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| R12 = 0x113 | This function writes the PL310 Prefetch Control Register with the input given value in R0. This function is available from Silicon Revision 2.2. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to set in the register |
| Output | | |
| Return | | |

27.5.2 Multicore Infrastructure Maintenance

Table 27-63. Read AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 Registers

| Function ID | Description | |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| R12 = 0x103 | Read both AUX_CORE_BOOT_0/1 registers. This function is kept for compatibility with ES1.0. AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 have memory-mapped access. See Chapter 4, Dual Cortex-A9 Subsystem . | |
| Parameters | | |
| Type | Location | Description |
| Input | | |

Table 27-63. Read AUX_CORE_BOOT_0 and AUX_CORE_BOOT_1 Registers (continued)

| Function ID | Description | |
|-------------|-------------|------------------------------------------------------------------|
| Output | R0 R1 | AUX_CORE_BOOT_0 register value AUX_CORE_BOOT_1 register value |
| Return | | |

Table 27-64. Modify AUX_CORE_BOOT_0

| Function ID | Description | |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| R12 = 0x104 | Modify the AUX_CORE_BOOT_0 register used as a status bit. The function sets and clears the bit given in the parameter and returns the new register value after operation. This function is kept for compatibility with ES1.0. AUX_CORE_BOOT_0 has memory-mapped access. See Chapter 4, Dual Cortex-A9 Subsystem . | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | Bit mask to set Bit mask to clear |
| Output | | |
| Return | R0 | AUX_CORE_BOOT_0 register new value |

Table 27-65. Write AUX_CORE_BOOT_1

| Function ID | Description | |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------|
| R12 = 0x105 | Set the value of the AUX_CORE_BOOT_1 register value used to give the CPU1 boot address. The given address can be virtual or physical. CPU1 MMU must be enabled before jumping to this address. This function is kept for compatibility with ES1.0. AUX_CORE_BOOT_1 has memory-mapped access. See Chapter 4, Dual Cortex-A9 Subsystem . | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to set in the register |
| Output | | |
| Return | | |

Table 27-66. Read WKG_CONTROL_0/1 Register

| Function ID | Description | |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|
| R12 = 0x106 | Function returns the value of the WKG_CONTROL_0/1 register (CPU0 or CPU1) depending on the input parameter value. This function is kept for compatibility with ES1.0. See the memory mapping and description in Chapter 4, Dual Cortex-A9 Subsystem . | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | CPU ID |
| Output | | |
| Return | R0 | Value of the WKG_CONTROL_0/1 register |

Table 27-67. Clear WKG_CONTROL_0/1 Register

| Function ID | Description | |
|-------------|--------------------------------------------------------------------------------------------------|--|
| R12 = 0x107 | This function clears the given bit mask of the WKG_CONTROL_0/1 register depending on the CPU ID. | |

Table 27-67. Clear WKG_CONTROL_0/1 Register (continued)

| Function ID | Description | |
|-------------------|-------------|-----------------------------|
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | CPU ID Bit Mask to clear |
| Output | | |
| Return | | |

27.5.3 Snoop Control Unit (SCU)

Table 27-68. Set Power Status Register

| Function ID | Description | |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| R12 = 0x108 | This function sets the power status register of the CPU and cleans the full CPU L1 data cache, if the cache will be switched OFF when CPU enters into low-power state. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 R1 | CPU power state value to set (0x2: CSWRET, 0x3: OFF) L1 data cache state (0x00: RET, 0xFF: OFF) |
| Output | | |
| Return | | |

27.5.4 Lockdown Translation Lookaside Buffers (TLBs)

Table 27-69. Select the TLB Entry for Read

| Function ID | Description | |
|-------------------|-----------------------------------------------------------------------|-------------|
| R12 = 0x10A | This function writes the Select Lockdown TLB Entry for Read register. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | TLB entry |
| Output | | |
| Return | | |

Table 27-70. Select the TLB Entry for Write

| Function ID | Description | |
|-------------------|------------------------------------------------------------------------|-------------|
| R12 = 0x10B | This function writes the Select Lockdown TLB Entry for Write register. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | TLB entry |
| Output | | |
| Return | | |

Table 27-71. Read the TLB VA Entry

| Function ID | Description | |
|-------------|---------------------------------------------------------------------------------|-----------------------|
| R12 = 0x10C | This function reads the Lockdown TLB VA register (Selected TLB Entry for Read). | |
| Parameters | | |
| Type | Location | Description |
| Input | | |
| Output | | |
| Return | R0 | Value of the register |

Table 27-72. Write the TLB VA Entry

| Function ID | Description | |
|-------------|--------------------------------------------------------------------------------------------------------------|----------------|
| R12 = 0x10D | This function writes the Lockdown TLB VA register (Selected TLB Entry for Write). The NS bit is forced to 1. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to write |
| Output | | |
| Return | | |

Table 27-73. Read the TLB PA Entry

| Function ID | Description | |
|-------------|---------------------------------------------------------------------------------|-----------------------|
| R12 = 0x10E | This function reads the Lockdown TLB PA register (Selected TLB Entry for Read). | |
| Parameters | | |
| Type | Location | Description |
| Input | | |
| Output | | |
| Return | R0 | Value of the register |

Table 27-74. Write the TLB PA Entry

| Function ID | Description | |
|-------------|-----------------------------------------------------------------------------------|----------------|
| R12 = 0x10F | This function writes the Lockdown TLB PA register (Selected TLB Entry for Write). | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to write |
| Output | | |
| Return | | |

Table 27-75. Read the TLB Attributes Entry

| Function ID | Description | |
|-------------|-----------------------------------------------------------------------------------------|-------------|
| R12 = 0x110 | This function reads the Lockdown TLB Attributes register (Selected TLB Entry for Read). | |
| Parameters | | |
| Type | Location | Description |
| Input | | |
| Output | | |

Table 27-75. Read the TLB Attributes Entry (continued)

| Function ID | Description | |
|-------------|-------------|-----------------------|
| Return | R0 | Value of the register |

Table 27-76. Write the TLB Attributes Entry

| Function ID | Description | |
|-------------|----------------------------------------------------------------------------------------------------------------------|----------------|
| R12 = 0x111 | This function writes the Lockdown TLB Attributes register (Selected TLB Entry for Write). The NS bit is forced to 1. | |
| Parameters | | |
| Type | Location | Description |
| Input | R0 | Value to write |
| Output | | |
| Return | | |

On-Chip Debug Support

This chapter describes the on-chip debug support.

28.1 Introduction

Debugging a system containing an embedded processor involves an environment that connects high-level debugging software, executing on a host computer, to a low-level debug interface supported by the target device. In between these levels is a debug and trace controller (DTC) that facilitates communication between the host debugger and the debug support logic on the target chip.

A combination of hardware and software that connects the host debugger to the target system, the DTC uses one or more hardware interfaces and/or protocols to convert actions dictated by the debugger user to JTAG commands and scans that execute the core hardware.

The debug software and hardware components let the user control multiple central processing unit (CPU) cores embedded in the device in a global or local manner. This environment provides:

- Synchronized global starting and stopping of multiple processors
- Starting and stopping of an individual processor
- Each processor can generate triggers that can be used to alter the execution flow of other processors.

System topics include but are not limited to:

- System clocking and power-down issues
- Interconnection of multiple devices
- Trigger channels

For easy integration into applications, a set of libraries (APIs) for debug-IP programming and software message library are being provided. CToolsLib is a collection of embedded target APIs/library to enable easy programmatic access to the chip tools (CTools), which are system-level debug facilities included in the debug subsystem capabilities of TI devices. More information about the APIs, download files, and other useful links for available libraries can be found on the CToolsLib Wiki site:

<http://processors.wiki.ti.com/index.php/CToolsLib>

The previous link(s) connect to TI community resources. Linked contents are provided "AS IS" by the respective contributors. They do not constitute TI specifications and do not necessarily reflect TI's views; see TI's [Terms of Use](#).

28.2 Debug Ports

28.2.1 IEEE1149.1

The target debug interface has the following signals:

- Five standard IEEE1149.1 JTAG signals: nTRST, TCK, TMS, TDI, and TDO
- A return clock (RTCK) due to the clocking requirements of the ARM968™ processor
- Two EMU [1:0] or five EMU [4:0] TI extensions, depending on the pin count (14 pins or 20 pins) in the JTAG header of the device.

Table 28-1 describes the IEEE1149.1 signals.

Table 28-1. IEEE1149.1 Signals

| Pin Name | Internal Signal Name | Type ⁽¹⁾ | Pull Type ⁽²⁾ | Function | Description |
|-------------------------|----------------------|---------------------|--------------------------|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| jtag_nrst | nTRST | I | PD | Test reset | When asserted (active low), causes all test and debug logic in the device to be reset along with the IEEE1149.1 interface |
| jtag_tck | TCK | I | PD | Test clock | This is the test clock used to drive an IEEE1149.1 test access port (TAP) state-machine and logic. This is a free-running clock or a gated clock, depending on the DTC attached to the device and the RTCK monitoring. |
| jtag_rtck | RTCK | O | N/A | Returned (synchronized) test clock | Depending on the DTC attached to the device, either the JTAG signals are clocked from RTCK or the RTCK is monitored by the DTC to the gate TCK. |
| jtag_tms_tmsc | TMS | I | PU | Test mode select | Directs the next state of the IEEE1149.1 TAP state-machine |
| jtag_tdi | TDI | I | PU | Test data input | Scans data input to the device |
| jtag_tdo | TDO | O | PU | Test data output | Scans data output by the device |
| dpm_emu0 | EMU0 | IO | PU | Emulation 0 | Channel 0 trigger OR boot mode OR trace port |
| dpm_emu1 | EMU1 | IO | PU | Emulation 1 | Channel 1 trigger OR boot mode OR trace port |
| dpm_emu2 ⁽³⁾ | EMU2 ⁽³⁾ | O | PD | Emulation 2 | Trace port |
| dpm_emu3 ⁽³⁾ | EMU3 ⁽³⁾ | O | PD | Emulation 3 | Trace port |
| dpm_emu4 ⁽³⁾ | EMU4 ⁽³⁾ | O | PD | Emulation 4 | Trace port |

⁽¹⁾ I = Input; O = Output

⁽²⁾ Internal pullup (PU)/pulldown (PD)

⁽³⁾ 20-pin JTAG header only

For information about the JTAG ID code value, see Table 1-3 through Table 1-6 in, *Introduction*.

28.2.2 IEEE1149.7

Besides the standard (legacy) JTAG mode of operation, the target debug interface can also be switched to a compressed JTAG mode of operation, commonly referred to as IEEE1149.7 standard. An IEEE1149.7 adapter module runs a 2-pin communication protocol on top of an IEEE1149.1 JTAG TAP. The debug-IP logic serializes the IEEE1149.1 transactions, using a variety of compression formats, to reduce the number of pins needed to implement a JTAG debug port. The device implements only a subset of the IEEE1149.7 protocol (see Table 28-3).

NOTE: At power-on-reset (POR), the default debug interface mode is IEEE1149.1. See the IEEE1149.7 specification for the scan sequence required to switch modes.

The IEEE1149.7 communication protocol can switch between serial and parallel formats. The parallel format consists of the IEEE1149.1 signals, TCK, TMS, TDI, TDO, nTRST, and a RTCK return clock, if stalls are required. The serial format uses two signals, TCK and TMSC. The values of the TMS, TDI, TDO, and RTCK signals are multiplexed on the bidirectional pin, jtag_tms_tmsc, by the Debug-IP logic. Each TCK of the DTC is serialized into a packet, which is transmitted to the IEEE1149.7 adapter, where it is converted back to parallel. The TDO and RTCK information are returned during the packet transmission.

NOTE: Only MScan, Oscan0, and Oscan4 formats can be used if the device requires stalls.

Table 28-2 describes the IEEE1149.7 signals.

Table 28-2. IEEE1149.7 Signals

| Pin Name | Internal Signal Name | Type ⁽¹⁾ | Pull Type ⁽²⁾ | Function | Description |
|---------------|----------------------|---------------------|--------------------------|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| jtag_tck | TCK | I | PD | Test clock | This is the test clock used to drive an IEEE1149.1 TAP state-machine and logic. This is a free-running clock or a gated clock, depending on the DTC attached to the device and the TMSC RDY field monitoring. |
| jtag_tms_tmsc | TMSC | I/O | PU | Test mode control and data scan | Compressed JTAG packet. The TMSC signal is driven only when the TCK signal is low. The signal level must be maintained by a keeper while the TCK signal is high. |

⁽¹⁾ I = Input; O = Output

⁽²⁾ Internal pullup (PU)/pulldown (PD)

Table 28-3 summarizes the IEEE1149.7 features subset supported by the device.

Table 28-3. IEEE1149.7 Features Subset

| | IEEE1149.7 Feature | Device Support | Comment |
|----------------------------|--------------------|-----------------------------|-------------------------------------|
| Configuration | Class 4 TAP | ✓ | Supports 2-pin operation |
| | Class 5 TAP | – | No BDX or CDX channel |
| Optional Components | FRST | – | Functional reset (done via ICEPick) |
| | TRST | – | Test reset |
| | RDBK capability | ✓ | Read back of register data |
| | Aux Pin Functions | – | Reuse of TDI and TDO pins |
| | TCKWID | ✓ | Programmable TCK width |
| Scan Formats | JScan0 | ✓ | Parallel mode |
| | JScan1 | ✓ | Parallel with firewall |
| | JScan2 | ✓ | Parallel with super-bypass select |

28.2.3 Trace Port

On-chip debug and trace events can be exported to external equipment through the trace port in the device. The following exportable debug events and trace sources are supported:

- Debug events
 - Triggers. For more information about triggers, see [Section 28.4.2, Cross-Triggering](#).
- Trace sources
 - Processor trace: Cortex-A9 MPU trace supported by program trace macrocell (PTM) and trace port interface unit (TPIU) modules. For more information about processor trace, see [Section 28.7, Processor Trace](#).
 - System trace: Trace coming from various system Instrumentation modules and supported by system trace module (STM). For more information about system trace, see [Section 28.8, System Instrumentation](#).

Note that not all debug and trace features can be supported concurrently due to limited amount of pins allocated to debug. Thus, a multiplexing among debug and trace sources is implemented. The configuration and the debug/trace source selection are done through the debug resource manager (DRM) module embedded in the debug subsystem.

[Table 28-4](#) describes the trace port signals.

Table 28-4. Trace Port Signals

| Pin Name | Internal Signal Name | I/O | Pull Type ⁽¹⁾ | Description |
|-----------|----------------------|-----|--------------------------|-------------------------------|
| dpm_emu19 | EMU19 | O | PD | Debug resource manager pin 19 |
| dpm_emu18 | EMU18 | O | PD | Debug resource manager pin 18 |
| dpm_emu17 | EMU17 | O | PD | Debug resource manager pin 17 |
| dpm_emu16 | EMU16 | O | PD | Debug resource manager pin 16 |
| dpm_emu15 | EMU15 | O | PD | Debug resource manager pin 15 |
| dpm_emu14 | EMU14 | O | PD | Debug resource manager pin 14 |
| dpm_emu13 | EMU13 | O | PD | Debug resource manager pin 13 |
| dpm_emu12 | EMU12 | O | PD | Debug resource manager pin 12 |
| dpm_emu11 | EMU11 | O | PD | Debug resource manager pin 11 |
| dpm_emu10 | EMU10 | O | PD | Debug resource manager pin 10 |
| dpm_emu9 | EMU9 | O | PD | Debug resource manager pin 9 |
| dpm_emu8 | EMU8 | O | PD | Debug resource manager pin 8 |
| dpm_emu7 | EMU7 | O | PD | Debug resource manager pin 7 |
| dpm_emu6 | EMU6 | O | PD | Debug resource manager pin 6 |
| dpm_emu5 | EMU5 | O | PD | Debug resource manager pin 5 |
| dpm_emu4 | EMU4 | O | PD | Debug resource manager pin 4 |
| dpm_emu3 | EMU3 | O | PD | Debug resource manager pin 3 |
| dpm_emu2 | EMU2 | O | PD | Debug resource manager pin 2 |
| dpm_emu1 | EMU1 | I/O | PU | Debug resource manager pin 1 |
| dpm_emu0 | EMU0 | I/O | PU | Debug resource manager pin 0 |

⁽¹⁾ Internal pullup (PU)/pulldown (PD)

NOTE: The dpm_emu[19:0] pins are shared with other functional (application) pins on the device boundary. To use the dpm_emu[19:0] pins, the user must program the device application pin manager (control module) appropriately. For more information, see [Chapter 18, Control Module](#).

For more information about DRM multiplexing and concurrent debug modes, see [Section 28.9, Concurrent Debug Modes](#).

28.2.4 End Product

For an end product phone, there are usually severe connectivity constraints and the standard debug ports may not be available at the board level. This can make it difficult to trace and debug software.

To ease tracing and debugging, a Narrow Interface for Debug and Test (NIDnT) concept defined by MIPI is used. NIDnT is based on IEEE1149.7 and STM interfaces and reuses application interface pins. In the context of the device, the application interface that can serve as an NIDnT port is the MMC1 interface. To use the NIDnT port, the relevant MMC1 pins must be set to the appropriate MUX mode through the control module.

[Table 28-5](#) shows the NIDnT port reuse of the MMC interface pins along with the corresponding MUX modes.

Table 28-5. NIDnT Port Reusing MMC Interface Pins

| Module | Control Module Multiplexing | | |
|-------------------------|-----------------------------|---------------|----------------------|
| | MUX0 (MMC) | MUX2 (STM) | MUX4 (IEEE1149.7) |
| Extension card (MMC) | sdmmc1_clk | dpm_emu19 | – |
| | sdmmc1_cmd | uart1_rx | – |
| | sdmmc1_dat0 | dpm_emu18 | – |
| | sdmmc1_dat1 | dpm_emu17 | – |
| | sdmmc1_dat2 | dpm_emu16 | jtag_tms_tmssc |
| | sdmmc1_dat3 | dpm_emu15 | jtag_tck |

NOTE: The nTRST signal must be driven high for the MMC1 interface to be used for IEEE1149.7 protocol.

NOTE: Uart1_rx is an optional return channel. Depending on the trace receiver, the return channel is implemented by IEEE1149.1/IEEE1149.7.

For more information about how to configure the proper MUX mode, see [Chapter 18, Control Module](#).

For more information about the NIDnT concept, see the *MIPI Alliance Test and Debug – NIDnT-Port* specification.

28.2.5 Trace Connector and Board Layout Considerations

Because the device supports processor trace and system trace export, a 60-pin header in place of the traditional TI 14-pin, or a TI 20-pin emulation header may be required at board level. For more information about the trace connectors and board layout considerations for these high-speed signals, see *Emulation and Trace Headers* (TI literature number SPRU655).

28.3 Debugger Connection

28.3.1 ICEPick Module

The debugger connects to the device through its JTAG interface. The first level of debug interface seen by the debugger is the IEEE1149.7 adapter connected to the ICEPick module embedded in the debug subsystem.

NOTE: ICEPick version D (ICEPick-D) is used in the device.

System-on-chip (SoC) designs typically have multiple processors, each having a JTAG test access port (TAP) embedded in the processor. The ICEPick module manages these TAPs and the power, reset, and clock controls for modules that have TAPs.

The ICEPick module is visible only from the debugger point of view, and thus cannot be programmed by application software. The debugger can configure ICEPick through its own TAP controller. The ICEPick TAP has an instruction length of 6 bits and is the primary TAP. It is always visible in the scan chain and is used to control and monitor the other secondary TAPs.

ICEPick provides the following debug capabilities:

- Debug connect logic for enabling or disabling most ICEPick instructions
- Dynamic TAP insertion
 - Serially linking up to 16 TAP controllers
 - Individually selecting one or more of the TAPs for scan without disrupting the instruction register (IR) state of other TAPs
- Power, reset, and clock management
 - Provides the power and clock states of each domain
 - Provides debugger control of the power domain of a processor. Can force the domain power and clocks on, and prohibit the domain from being clock-gated or powered down while a debugger is connected.
 - Applies system reset
 - Provides wait-in-reset (WIR) boot mode
 - Provides global and local WIR release
 - Provides global and local reset blocking

The ICEPick module implements a connect register, which must be configured with a predefined key to enable the full set of JTAG instructions. Once the debug connect key is properly programmed, ICEPick signals and subsystems emulation logics must be turned on.

For more information about ICEPick dynamic TAP insertion, see [Section 28.3.3, Dynamic TAP Insertion](#).

For more information about ICEPick power, reset, and clock management features, see [Section 28.5, Power, Reset, and Clock Management Debug Support](#).

28.3.2 Boot Modes

The initial configuration of ICEPick is determined by the level of the dpm_emu0 and dpm_emu1 pins upon POR release. At POR, dpm_emu0 and dpm_emu1 are automatically configured as inputs. The dpm_emu0 and dpm_emu1 pins are free once POR is released.

[Table 28-6](#) summarizes the ICEPick boot modes.

Table 28-6. ICEPick Boot Modes Upon POR

| dpm_emu1 | dpm_emu0 | TAPs in the TDI → TDO Path | Other Effects/Comments |
|----------|----------|----------------------------|-------------------------------|
| 0 | 0 | None | Reserved (do not use) |
| 0 | 1 | None | Reserved (do not use) |
| 1 | 0 | ICEPick | TAP only + wait-in-reset mode |

Table 28-6. ICEPick Boot Modes Upon POR (continued)

| dpm_emu1 | dpm_emu0 | TAPs in the TDI → TDO Path | Other Effects/Comments |
|----------|----------|----------------------------|-------------------------|
| 1 | 1 | ICEPick | TAP only (default mode) |

28.3.2.1 Default Boot Mode

In ICEPick-only configuration, none of the secondary TAPs are selected. The ICEPick TAP is the only TAP between device-level TDI and TDO pins. This is the recommended boot mode.

28.3.2.2 Wait-In-Reset

The device can boot to invoke WIR mode. If the device is booted in this mode, all processors within the device that support a TAP through ICEPick are held in reset until released. Individual processors may be released from reset (local), or all processors held in the reset state may be released at the same time (global).

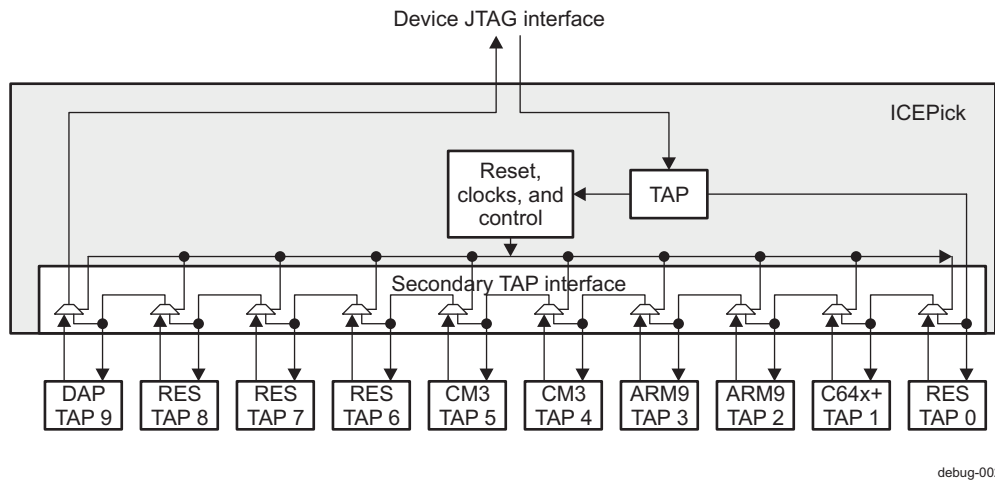

28.3.3 Dynamic TAP Insertion

28.3.3.1 ICEPick Secondary TAPs

To include more or fewer secondary TAPs in the scan chain, the debugger must use the ICEPick TAP router to program the TAPs. At its root, ICEPick is a scan-path linker that lets the DTC selectively choose which subsystem TAPs are accessible through the device-level debug interface. Each secondary TAP can be dynamically included in or excluded from the scan path. From external JTAG interface point of view, secondary TAPs that are not selected appear not to exist.

Figure 28-1 shows the TAPs in the ICEPick scan chain.

Figure 28-1. ICEPick Scan Chain

28.4 Primary Debug Support

28.4.1 Processor Native Debug Support

28.4.1.1 Cortex-A9 MPU

The dual Cortex-A9 processor supports the following native debug features:

- Halt mode and monitor mode debugging
- Six breakpoints and four watch points
- Asynchronous aborts
- Performance monitoring
- Cross-triggering: Allows stopping one CPU upon debug event (for example, breakpoint) detection in the other CPU

For more information about Cortex-A9 native debug support features, see the *Cortex-A9 Technical Reference Manual*.

28.4.1.2 Cortex-M3 MPU

The Cortex-M3 processor supports the following native debug features:

- Program halt and stepping
- Hardware breakpoints, breakpoint instruction
- Data watch point on access to data add, add range, and data value
- Register value accesses
- Debug monitor exception
- Memories accesses

For more information about Cortex-M3 native debug support features, see the *Cortex-M3 Technical Reference Manual*.

28.4.1.3 DSP

The DSP core supports limited Advanced Event Triggering (AET), with the following capabilities:

- Hardware program breakpoints: Specify addresses or address ranges that can generate events such as halting the processor or triggering the trace capture
- Data watch points: Specify data variable addresses, address ranges, or data values that can generate events such as halting the processor or triggering the trace capture

Known restrictions of this DSP core:

- No DSP processor trace support
- No real-time mode debug mode support
- Limited AET support, only two watch point units
- No HSRTDX support

28.4.1.4 IVA-HD ARM968

The ARM968E-S processor supports the following native debug features through its EmbeddedICE-RT logic:

- Two hardware watch points/breakpoints
- Halt mode and monitor mode debugging
- Debug control and status registers
- Debug communications channel

For more information about ARM968 native debug support features, see the *ARM968E-S Technical Reference Manual*.

28.4.1.5 IVA-HD Hardware Accelerators

Hardware accelerators offer the following debug capabilities through their embedded SyncBox module:

- Manual halt: Halt occurs at the SyncBox task boundary, when requested by the debugger
- Single-step execution at SyncBox task level (from 1 to n macroblocks depending on the user software)
- Cross-triggering: Hardware accelerator can halt, after the execution of current SyncBox task, based on trigger event detection
- Global run

[Table 28-9](#) summarizes the debug capabilities of the hardware accelerator SyncBox.

Table 28-9. Hardware Accelerator Debug Capability Options

| Feature | iME3 | iPE3 | MC3 | CALC3 | iLF3 | ECD3 |
|--------------------------------|------|------|-----|-------|------|------|
| Core reset | - | - | - | - | - | - |
| Execution request | - | - | - | - | - | - |
| Trigger output | - | - | - | - | - | - |
| Trigger input | ✓ | ✓ | ✓ | ✓ | ✓ | ✓ |
| Number of trigger channels | 1 | 1 | 1 | 1 | 1 | 1 |
| Number of counters | 0 | 0 | 0 | 0 | 0 | 0 |
| Number of watch points | 0 | 0 | 0 | 0 | 0 | 0 |
| Number of hardware breakpoints | 0 | 0 | 0 | 0 | 0 | 0 |

28.4.2 Cross-Triggering

The device supports a cross-triggering feature, which provides a way to propagate debug (trigger) events from one processor subsystem/module to another. For example, a given *subsystem A* can be programmed to generate a debug event, which can then be exported as a global trigger across the device. Another *subsystem B* can be programmed to be sensitive to the trigger line input and to generate an action upon trigger detection.

Examples of debug events are: processor entering debug state, watch point match, PTM trigger, ETB full, ETB acquisition complete, etc.

Examples of debug actions are: debug request generation, restart (Cortex-A9 synchronous run), interrupt request generation, start/stop trace, etc.

Subsystems cross-triggering is consolidated at the device level by the XTRIGGER module, which is embedded in the debug subsystem.

NOTE: XTRIGGER is not programmatically visible from the JTAG interface or any device processor. Thus, cross-triggering is programmed at the subsystem level.

28.4.2.1 SOC Level Cross-Triggering

Table 28-10 summarizes the device cross-triggering capabilities.

Table 28-10. XTRIGGER

| Subsystem | Module | | Cortex-A9 | PTM/E TB | Cortex-M3 | Cortex-M3 | Target Core | IVA3-C64x | IVA-HD ARM968 | IVA-HD ARM968 | HWA | PMI | CMI | OCP-WP | EMU0/EMU1 |
|------------------------------|--------------|--------------------------------|-----------|----------|-----------|-----------|-------------|-----------|---------------|---------------|-----|-----|-----|--------|-----------|
| | | Trigger Input / Trigger Source | ✓ | ✓ | ✓ | ✓ | - | ✓ | ✓ | ✓ | - | ✓ | ✓ | ✓ | ✓ |

| Device | OCP-WP | ✓ | ✓ | ✓ | ✓ | ✓ | - | ✓ | ✓ | ✓ | - | ✓ | ✓ | | ✓ |
| | EMU0, EMU1 | ✓ | ✓ | ✓ | ✓ | ✓ | - | ✓ | ✓ | ✓ | - | ✓ | ✓ | ✓ | |

NOTE: The following modules support only trigger inputs:

- IVA-HD hardware accelerators
- IVA-HD SMSET
- PMI
- CMI

28.4.3 Suspend

The device supports a suspend feature, which provides a way to stop a "closely coupled" hardware process running on a peripheral-IP when the host processor enters debug state. The suspend mechanism is important for debug to ensure that peripheral-IPs operate in a lock-step manner with a host controller processor.

An entry is provided for each peripheral-IP that must consider the suspend signals from a number of processors (MPU or DSP). For each peripheral-IP, sensitivity to the suspend signals is defined within two possibilities (and so coded using 1bit):

- Peripheral-IP is sensitive to the suspend line request.
- Peripheral-IP ignores the suspend line request.

For more information about how to program the sensitivity, see the corresponding peripheral-IP TRM chapter.

28.4.3.1 Debug Aware Peripherals and Host Processors

Table 28-11 lists the mapping of the device processors to the suspend control input lines.

Table 28-11. Debug Subsystem Suspend Input Lines

28.5 Power, Reset, and Clock Management Debug Support

The global PRCM module implements facilities to support debug across power and clock domain cycles. The debugger can control or get the status of each power and clock domain associated with an ICEPick secondary TAP.

ICEPick provides a set of directives allowing the debugger to:

- Get visibility on the associated power and clock domains state. This includes:
 - Current power setting indicating whether the power domain is on or off
 - Loss of power detected since the software last checked the status
 - Current clock setting indicating whether the clock domain is on or off
 - Sleep desired (PM and CM indicate that the debug settings in ICEPick are changing the application state. If it were not for the ICEPick controls, the power or clock would be turned off.)
 - Subsystem reset state
 - Subsystem has entered a debug state that requires the attention of the host debug software.
- Override power/clock control settings to wake up a power or clock domain or to prevent a power or clock domain from going to sleep once it is in ACTIVE state
- Assert/block/extend reset; release from extended reset (WIR)

ICEPick handles debug power management at the device level. In addition, the device implements a second level of debug power management through the DAP-PC module integrated in the Cortex-A9 MPU subsystem, which provides the same capabilities as ICEPick for the two Cortex-A9 CPUs. Each Cortex-A9 CPU core is in its own independent power domain, which DAP-PC manages. The hierarchical debug power-management approach provided by DAP-PC at the subsystem level and by ICEPick at the device level ensures a theoretically independent debug capability for each Cortex-A9 CPU core.

NOTE: The debugger must properly sequence global ICEPick and local DAP-PC commands:

- To force clocks/power:
 1. The debugger must first force it for the Cortex-A9 MPU subsystem at the ICEPick level.
 2. The debugger must then force it for a specific Cortex-A9 CPU at the DAP-PC level.
 - To release clocks/power:
 1. The debugger must first release it for a specific Cortex-A9 CPU at the DAP-PC level.
 2. The debugger must then release the Cortex-A9 MPU subsystem controls at the ICEPick level.
-

28.6 Performance Monitoring

28.6.1 Cortex-A9 MPU Subsystem Performance Monitoring

28.6.1.1 Performance Monitoring Unit

The Cortex-A9 processor includes a performance monitoring unit (PMU) that enables events, such as cache misses and instructions executed, to be counted over a period of time. The PMU provides six counters to gather statistics about the operation of the processor and memory system. Each counter can count any of the events available in Cortex-A9.

The Cortex-A9 PMU outputs 52 events (PMUEVENT[51:0]) to PTM (see [Table 28-13](#)).

Table 28-13. PMU Events

| PMU Event | Description |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------|
| 0 | Software increment |
| 1 | Instruction fetch that causes a refill |
| 2 | Instruction fetch that causes a TLB refill |
| 3 | Data read or write operation that causes a refill |
| 4 | Data read or write operation that causes a cache access |
| 5 | Data read or write operation that causes a TLB refill |
| 6 | Data read architecturally executed |
| 7 | Data write architecturally executed |
| 8, 9 | Number of instructions renamed: b00 = No instructions renamed b01 = One instruction renamed b10 = Two instructions renamed |
| 10 | Exception taken |
| 11 | Exception return architecturally executed |
| 12 | Change to context ID retired |
| 13 | Software change of PC |
| 14 | Immediate branch architecturally executed |
| 15 | Number of predictable function returns |
| 16 | Unaligned access architecturally executed |
| 17 | Branch mispredicted or not predicted |
| 18 | Branches or other change in program flow |
| 19 | Java byte code executed |
| 20 | Software Java byte code executed |
| 21 | Jazelle backward branches executed |
| 22 | Coherent line fill request that misses in other uniprocessors |
| 23 | Request for coherent line fill that hits in other uniprocessors |
| 24 | Instruction cache dependent stalls |
| 25 | Data cache dependent stalls |
| 26 | TLB miss dependent stalls |
| 27 | STREX passed |
| 28 | STREX failed |
| 29 | Data eviction |
| 30 | Issue does not dispatch any instruction. |
| 31 | Issue is empty. |
| 32 | Main execution unit pipe |
| 33 | Second execution unit pipe |
| 34 | Load/store pipe |

Table 28-13. PMU Events (continued)

| PMU Event | Description |
|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 35, 36 | Number of floating-point instructions renamed: b00 = No floating-point instruction renamed b01 = One floating-point instruction renamed b10 = Two floating-point instructions renamed |
| 37, 38 | Number of NEON instructions renamed: b00 = No NEON instruction renamed b01 = One NEON instruction renamed b10 = Two NEON instructions renamed |
| 39 | PLD stall |
| 40 | Write stall |

| 42 | Data main TLB miss stall |
| 43 | Instruction micro TLB miss stall |
| 44 | Data micro TLB miss stall |
| 45 | DMB stall |
| 46 | Integer core clock enabled |
| 47 | Data engine clock enabled |
| 48 | ISB |
| 49 | DSB |
| 50 | DMB |
| 51 | External interrupt |

For more information about Cortex-A9 PMU, see the *ARM Cortex-A9 Technical Reference Manual*.

28.6.1.2 Snoop Control Unit

The individual CPU event monitors can be configured to gather statistics about the operation of the snoop control unit (SCU).

28.6.1.3 L2 Cache (PL310)

The Cortex-A9 MPU subsystem includes 512KB of L2 cache and uses PL310 as the L2 cache controller. The PL310 includes logic to support cache event monitoring.

[Table 28-14](#) summarizes the PL310 L2 cache events.

Table 28-14. PL310 L2 Cache Events

| Event | Event Description |
|-------|--------------------------------------------------------------------------------------------------------|
| 0 | Eviction of a line from the L2 cache |
| 1 | Data read hit in the L2 cache |
| 2 | Data read lookup to the L2 cache. Subsequently results in a hit or miss. |
| 3 | Data write hit in the L2 cache |
| 4 | Data write lookup to the L2 cache. Subsequently results in a hit or miss. |
| 5 | Data write lookup to the L2 cache with Write-Through attribute. Subsequently results in a hit or miss. |
| 6 | Instruction read hit in the L2 cache |
| 7 | Instruction read lookup to the L2 cache. Subsequently results in a hit or miss. |
| 8 | Prefetch line-fill sent to L3 |
| 9 | Allocation into the L2 cache caused by a write (with Write-Allocate attribute) miss |

The PL310 implements two 32-bit event counters. The PL310 can be configured to generate interrupts on error conditions or event counter overflow or increment. The PL310 interrupt is routed to MA_IRQ_0. When an interrupt occurs, software can look at the relevant interrupt status register to determine the source of the interrupt.

For more information about PL310, see the *ARM PrimeCell Level 2 Cache Controller (PL310) Technical Reference Manual*.

28.6.2 Cortex-M3 MPU Subsystem Performance Monitoring

28.6.2.1 Subsystem Counter Timer Module

The dual Cortex-M3 MPU subsystem includes a subsystem counter timer module (SCTM), which is embedded in shared cache and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect:

- Forty-four shared cache events
- Four sleep/deep-sleep events from Cortex-M3 cores (one sleep and one deep sleep event per core)

[Table 28-15](#) describes the repartition of the Cortex-M3 SCTM counters.

Table 28-15. Cortex-M3 SCTM Counters Repartition

| Counters | Features |
|----------|----------------------------|
| 0–1 | Timer and event |
| 2–3 | 64-bit chained + shadowing |
| 4–5 | 64-bit chained + shadowing |
| 6–7 | Event |

28.6.2.2 Cache Events

[Table 28-16](#) summarizes the SCTM events for the Cortex-M3 MPU subsystem.

Table 28-16. SCTM Events for Cortex-M3 MPU Subsystem

| Input Index | Event Description |
|-------------|----------------------------------------|
| 1 | Cache locks |
| 2 | Cache line replacements |
| 3 | Cache evictions |

28.6.3 DSP Subsystem Performance Monitoring

28.6.3.1 Subsystem Counter Timer Module

The DSP subsystem includes an SCTM, which is embedded in the DSP megamodule and provides additional data to the user timing or profiling capability. SCTM integrates eight profiling counters that collect L1 and L2 events.

[Table 28-15](#) describes the repartition of the DSP SCTM counters.

Table 28-17. DSP SCTM Counters Repartition

| Counters | Features |
|----------|---------------------|
| 0–1 | Timer and event |
| 2–7 | Event (no chaining) |

28.6.3.2 L1 and L2 Events

Table 28-18 summarizes the SCTM events for DSP subsystem.

Table 28-18. SCTM Events for DSP Subsystem

| Event | Event Description |
|--------------|---------------------------------------------------|
| 1 | L1 Slave0 (program) tag hit |
| 2 | L1 Slave1 (data) tag hit |
| 3 | L1 Slave0 (program) tag miss |
| 4 | L1 Slave1 (data) tag miss |
| 5 | L1 Slave0 (program) fill buffer hit |
| 6 | L1 Slave1 (data) fill buffer hit |
| 7 | L1 Slave1 (data) write buffer access |
| 8 | L1 Allocation FIFO |

| 10 | L1 Slave1 (data) bank conflict |
| 11 | L1 Slave0 (program) cached request |
| 12 | L1 Slave1 (data) cached request |
| 13 | L1 Slave0 (program) waiting for fill buffer |
| 14 | L1 Slave1 (data) waiting for fill buffer |
| 15 | L1 Slave0 (program) waiting for maintenance |
| 16 | L1 Slave1 (data) waiting for maintenance |
| 17 | L1 Eviction occurred |
| 18 | L1 Replacement occurred |
| 19 | L1 Allocation failed due to locked lines occurred |
| 20 | L2 tag hit |
| 21 | L2 tag miss |
| 22 | L2 fill buffer hit |
| 23 | L2 write buffer access |
| 24 | L2 allocation FIFO |
| 25 | L2 cached request |
| 26 | L2 waiting for fill buffer |
| 27 | L2 waiting for maintenance |
| 28 | L2 eviction occurred |
| 29 | L2 replacement occurred |
| 30 | L2 allocation failed due to locked lines occurred |
| 31 | Tied-off to 0 |

NOTE: Input index [0] is reserved for the free-running subsystem clock (used for total cycle profiling).

28.7 Processor Trace

The device supports only Cortex-A9 processor trace. The main Cortex-A9 processor trace characteristics are:

- Program trace only (no data trace)
- Separate PTM for each Cortex-A9 CPU
- Trace can be:
 - Exported off-chip through TPIU in the debug subsystem (maximum number of trace data pins = 18)
 - Stored on-chip to ETB through CS-TF in the debug subsystem
- Trace can be optionally:
 - Cycle accurate useful for profiling sections of code
 - Interleaved dynamically between the two Cortex-A9 CPUs by a CS-TF embedded in the Cortex-A9 MPU subsystem

NOTE: Depending on the use case, the device may not be able to interleave two cycle accurate traces without overflow (bandwidth restriction).

Figure 28-2 shows an overview of the processor trace flow.

Figure 28-2. Processor Trace Flow

debug-004

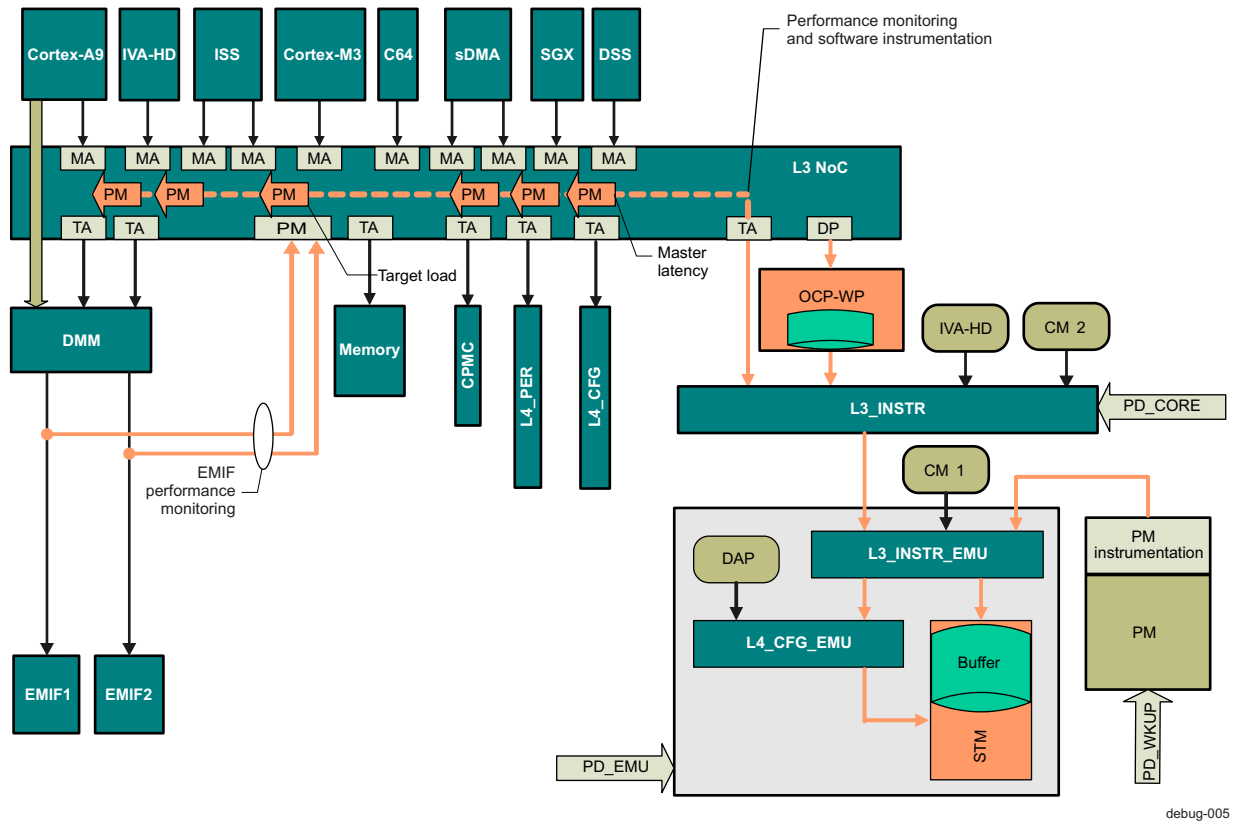

28.8 System Instrumentation

The device supports the following system instrumentation features:

- Real-time software trace (see Section 28.8.2, *Software Instrumentation*)
- OCP target traffic monitoring (see Section 28.8.3, *OCP Watch-Point*)
- OCP target load and master latency monitoring (see Section 28.8.5, *NoC Statistics Collector*)
- HWA load monitoring (see Section 28.8.4, *IVA-HD Pipeline*)
- PM events trace (see Section 28.8.6, *PM Instrumentation [PMI]*)
- CM events trace (see Section 28.8.7, *CM Instrumentation [CMI]*)

Figure 28-3 is an overview of the device system instrumentation framework.

Figure 28-3. System Instrumentation Framework

28.8.1 MIPI STM

MIPI-STM is a trace module that aids in software debugging. The main features of this module are:

- Implements MIPI STP protocol (rev 1.0) with the following characteristics:
 - Highly optimized for software-generated traces
 - Automatic timestamping of messages
 - Support for 8-, 16-, and 32-bit data types
- Collects the following information:
 - Software messages
 - Hardware instrumentation trace from hardware agents:
 - OCP-WP
 - PMI
 - CMI

- SMSET
- L3 NoC statistics collectors
- Exports trace data to:
 - External trace receiver
 - On-chip ETB buffer
- Available in 1-, 2-, or 4-pin mode with single- or dual-edge clock, depending on the trace bandwidth requirements and characteristics of the trace receiver
- Dedicated 128 × 32-bit FIFO buffer

A maximum of 255 different bus masters can be connected to the STM trace port through a bus arbiter. STP recognizes two distinct modes of tracing (software and hardware types), which use slightly different message combinations to output different types of data. The bus masters can be configured for either type to optimize the system for the different types of trace data.

28.8.2 Software Instrumentation

The device provides support for real-time software trace through user-defined message writes to specific memory mapped register (MMR) locations. Software masters can transmit trace data from the operating system (OS) processes or tasks on 256 different channels, with each channel being defined by the software protocol implemented. The different channels can be used to group different types of data logically so that it is easy to filter out the data irrelevant to the on-going debugging task. The message structures in STP are optimized to provide an efficient transport for software data through the STM module.

The software masters are:

- Cortex-A9 MPU subsystem
- DAP (for testing purpose)
- DSP subsystem
- Dual Cortex-M3 MPU subsystem
- sDMA controller write port (SDMA_WR)
- IVA-HD subsystem

Each software master has a master-ID assigned to it.

Software messages can be interleaved with other hardware messages.

Software messages are intrusive and use both processor cycles and memory.

28.8.3 OCP Watch-Point

The L3 interconnect provides five functional probes embedded and attached to the following L3 targets:

- GPMC
- L4-PER
- L4-CFG
- DMM1 (DMM target port 1)
- DMM2 (DMM target port 2)

The probes output are muxed together and then sent to the L3 interconnect debug port. A component called OCP-WP is used to collect data from functional probes and then transmit captured data to the STM module. The OCP-WP drives a Probe-ID signal to the L3 interconnect for probe selection. The probe selection is exclusive, meaning that interleaving is not possible.

The OCP-WP provides the following main features:

- Monitoring the OCP traffic originated by all initiators that can access the selected target where the probe is attached
- Filtering OCP monitored bus traffic by:
 - Address range

- Initiator-ID (see [Table 28-20](#))
- Transaction type
- Transaction qualifier
- Generating a trigger upon watch-point match
- Starting and stopping OCP traffic monitoring upon:
 - WP address match
 - External trigger
- OCP-WP messages can be interleaved with software messages
- Programming from:
 - Debugger
 - Application

NOTE: The OCP-WP is restricted to monitor request flow.

[Table 28-19](#) summarizes the OCP targets that can be monitored by the OCP-WP and their respective probe-ID.

Table 28-19. L3 Interconnect Functional Probe Mapping

| Probe-ID | L3 OCP Target |
|----------|--------------------------|
| 000 | Reserved |
| 001 | GPMC |
| 010 | L4-PER |
| 011 | L4-CFG |
| 100 | DMM1 (DMM target port 1) |
| 101 | DMM2 (DMM target port 2) |
| 110 | Reserved |
| 111 | Reserved |

[Table 28-20](#) summarizes the ConnID (Initiator-ID) mapping from a debug point of view.

Table 28-20. ConnID Mapping (Debug View)

| ConnID | Initiator |
|--------|------------------------------------------|
| 0x0 | Cortex-A9 MPU subsystem |
| 0x4 | CS-DAP |
| 0x8 | DSP |
| 0xC | IVA-HD |
| 0xD | IVA-HD iCONT1 (software instrumentation) |
| 0xE | IVA-HD iCONT2 (software instrumentation) |
| 0x10 | ISS |
| 0x11 | Dual Cortex-M3 MPU subsystem |
| 0x12 | Face detect |
| 0x14 | sDMA_RD |
| 0x15 | sDMA_WR |
| 0x18 | SGX |
| 0x1C | Display subsystem |
| 0x24 | HSI |
| 0x28 | MMC1 |
| 0x29 | MMC2 |
| 0x30 | HSUSBHOST |

Table 28-20. ConnID Mapping (Debug View) (continued)

| ConnID | Initiator |
|--------------|-----------|
| 0x31 | HSUSBOTG |
| 0x32 | FSUSB |
| Other values | Reserved |

NOTE: For information about ConnID values from a protection/error logging point of view, see [Section 13.2.3.2.3, Master NIU Identification](#), in [Chapter 13, Interconnect](#).

28.8.4 IVA-HD Pipeline

The device takes advantage of the system trace infrastructure to provide visibility to the user regarding IVA-HD micro-task sequencing. This is supported through a SMSET module instantiated in the IVA-HD subsystem. The micro-task boundaries are handled as generic events and encapsulated in STP messages with an event-ID and local timestamp and exported through the MIPI-STM module.

The IVA-HD instrumentation scheme allows the user to understand micro-task dependencies, hardware accelerators load balancing, and potential bottlenecks. DMA transfer boundaries are reported as IVA-HD events. Software messages from ARM968 execution can be interleaved with IVA-HD events.

28.8.5 NoC Statistics Collector

The L3 interconnect supports a built-in performance monitoring feature by implementing a statistics collector (SC) component, which computes traffic statistics within a user-defined window and periodically reports to the user through the MIPI-STM interface. Three SC instances are instantiated in the device:

- One statistics collector dedicated to SDRAM load monitoring – SC_SDRAM (see [Section 28.8.5.1, L3 Target Load Monitoring](#), for more information)
- Two statistics collectors dedicated to master latency monitoring – SC_LAT0 and SC_LAT1 (see [Section 28.8.5.2, L3 Master Latency Monitoring](#), for more information)

Statistics collectors (SDRAM and LAT0/1) can report:

- Average burst length in bytes/packet per sampling window
- Average throughput in bytes/cycle
- % Link occupancy on the request link (for store transactions) during a sampling window
- % Link occupancy on the response link (for load transactions) during a sampling window
- % Arbitration conflict cycles on the request link
- % Initiator busy cycles on the response link
- Histogram of payload length in bytes (for example, 0–16 , 16–32, 32–128) each sampling window.
- Histogram of quality of service (QoS) metric for IVA-HD initiator (for example, low priority, high priority) each sampling window.

The performance metrics are interleaved with software instrumentation data at the L3 interconnect level.

The performance monitoring probes implement three main functions:

- Events detection
- Transactions filtering
- Aggregation

The probes can be configured to detect the events summarized in [Table 28-21](#).

Table 28-21. Performance Monitoring Events Detection

| Event | Definition |
|----------|--------------------------------------------------------------------------------|
| NONE | No event selected |
| ANY | Any clock cycles |
| TRANSFER | Word has been accepted by the receiver. |
| WAIT | Transfer has been initiated but the transmitter currently has no data to send. |
| BUSY | Receiver applies flow control |
| PKT | Transfer of a new packet header |
| DATA | Transfer of a payload word |
| IDLES | No communication over the link |
| LATENCY | Debug bit detection |

The probes can be configured to filter the traffic based on the criteria summarized in [Table 28-22](#).

Table 28-22. Performance Filtering Options

| Probe Filtering Options | Comment |
|------------------------------|----------------|
| Master address | Mask and match |
| Slave address ⁽¹⁾ | |
| UserInfo | |
| Read | |
| Write | |
| Error | |

⁽¹⁾ SC_LAT0/1 only

The probes implement a user-defined set of counters that aggregate the events sampled by the detector and filtered according to the user setup.

NOTE: Statistics collectors counter values are not accessible by application software.

[Table 28-23](#) summarizes the performance probe aggregation modes.

Table 28-23. Aggregation Modes

| Aggregation Mode | Description |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FILTER_HIT | The counter increments by 1 when the filter hits. |
| MIN_MAX_HIT | The counter increments by 1 when the filter hits and the selected event information is within range. <ul style="list-style-type: none"> - Payload length (bytes) - Pressure value - Request/response latency (clock cycles) |
| EVT_INFO | The selected event information is added to the counter value when the filter hits. <ul style="list-style-type: none"> Payload length (bytes) Pressure value Request/response latency (clock cycles) |
| AND_FILTER | The counter increments by 1 when all unit filters hit. |
| OR_FILTER | The counter increments by 1 when at least one unit filter hits. |
| SUM_REQ_EVT | The counter sums the events from any request port. |
| SUM_RSP_EVT | The counter sums the events from any response port. |
| SUM_ALL_EVT | The counter sums the events from any port. |
| EXT_EVT | The counter increments by 1 when selected external event input signal is sampled high. |

28.8.5.1 L3 Target Load Monitoring

The L3 interconnect implements three performance monitoring probes on LPDDR2 memory channels. The traffic statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

SC_SDRAM supports the following main features:

- Three probe inputs
 - Probe 0 – EMIF1 (DMM-EMIF1 128-bit port)
 - Probe 1 – EMIF2 (DMM-EMIF2 128-bit port)
 - Probe 2 – Reserved
- Five 16-bit counters shared concurrently
 - Counter 0 with two filters
 - Counter 1 with one filter
 - Counter 2 with two filters
 - Counter 3 with one filter
 - Counter 4 without any filter
- Simple (with one element) or complex (with several elements) filters available
- Filtering according to:
 - Initiator of traffic
 - Access priorities
- No latency counter. Only bandwidth measurement on this collector
- 16-bit collecting window counter
- Dump Identifier is 0x0 (tie-off value)
- Dumps frames at L3 interconnect slave address 0x19 (debug subsystem)

Table 28-24 summarizes the SC_SDRAM configuration.

Table 28-24. SC_SDRAM Configuration

| Counters | Min Max | Filter Elements | L3 Target | | |
|-----------|------------|-----------------|-----------|-------|----------|
| | | | EMIF1 | EMIF2 | Reserved |
| Counter 0 | Yes | 2 | EMIF1 | EMIF2 | Reserved |
| Counter 1 | Yes | 1 | EMIF1 | EMIF2 | Reserved |
| Counter 2 | Yes | 2 | EMIF1 | EMIF2 | Reserved |
| Counter 3 | Yes | 1 | EMIF1 | EMIF2 | Reserved |
| Counter 4 | Yes | No | No | No | Reserved |

28.8.5.2 L3 Master Latency Monitoring

The device L3 interconnect implements nine performance monitoring probes on the main L3 initiators:

- Cortex-A9 MPU subsystem
- DSP
- sDMA controller read port (SDMA_RD)
- sDMA controller write port (SDMA_WR)
- IVA-HD
- DSS
- ISS
- SGX
- Dual Cortex-M3 MPU subsystem

The master latency statistics are computed within a user-defined window and periodically reported to the user through the MIPI-STM interface.

The probes can be configured to filter latencies in four classes and report to the user a latency distribution along execution.

Because the performance metrics and the software events are exported through a unified export channel, it is possible to correlate latency trends with on-going execution and system context.

Because computing latency requires maintaining the state between request and response ports, the probe cannot compute latency statistics on 100 percent of the initiator traffic. Hence, latency histograms must be extracted on large execution windows to be accurate.

28.8.5.2.1 SC_LAT0 Configuration

SC_LAT0 supports the following main features:

- Six probe inputs:
 - Probe 0: Cortex-A9 MPU subsystem
 - Probe 1: DSP subsystem
 - Probe 2: SDMA_RD
 - Probe 3: SDMA_WR
 - Probe 4: DSS
 - Probe 5: ISS
- Four 16-bit counters shared concurrently:
 - Counter 0 with one filter
 - Counter 1 with one filter
 - Counter 2 with one filter
 - Counter 3 with one filter
- Filtering according to:
 - L3 target
 - Access priorities
- 10-bit counter for latency measurement
- 16-bit collecting window counter
- Identifier is 0x1 (tie-off value)
- Dumps frames at slave address 0x19 (DEBUGSS)

Table 28-25 summarizes the SC_LAT0 configuration.

Table 28-25. SC_LAT0 Configuration

| Counters | Min Max | Filter Elements | L3 Master | | | | | |
|-----------|------------|--------------------|----------------------------|-----|---------|---------|-----|-----|
| | | | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS |
| Counter 0 | Yes | 1 | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS |
| Counter 1 | Yes | 1 | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS |
| Counter 2 | Yes | 1 | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS |
| Counter 3 | Yes | 1 | Cortex-A9 MPU subsystem | DSP | SDMA_RD | SDMA_WR | DSS | ISS |

28.8.5.2.2 SC_LAT1 Configuration

SC_LAT1 supports the following main features:

- Five probe inputs:

- Probe 0: IVA-HD
- Probe 1: Cortex-A9 MPU subsystem
- Probe 2: SDMA_WR
- Probe 3: SGX
- Probe 4: Dual Cortex-M3 MPU subsystem
- Four 16-bit counters shared concurrently:
 - Counter 0 with one filter
 - Counter 1 with one filter
 - Counter 2 with one filter
 - Counter 3 with one filter
- Filtering according to:
 - L3 target
 - Access priorities
- 10-bit counter for latency measurement
- 16-bit collecting window counter
- Identifier is 0x2 (tie-off value)
- Dumps frames at slave address 0x19 (DEBUGSS)

Table 28-26 summarizes the SC_LAT1 configuration.

Table 28-26. SC_LAT1 Configuration

| Counters | Min Max | Filter Elements | L3 Master | | | | |
|-----------|------------|-----------------|-----------|-------------------------|---------|-----|------------------------------|
| | | | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX | Dual Cortex-M3 MPU subsystem |
| Counter 0 | Yes | 1 | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX | Dual Cortex-M3 MPU subsystem |
| Counter 1 | Yes | 1 | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX | Dual Cortex-M3 MPU subsystem |
| Counter 2 | Yes | 1 | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX | Dual Cortex-M3 MPU subsystem |
| Counter 3 | Yes | 1 | IVA-HD | Cortex-A9 MPU subsystem | SDMA_WR | SGX | Dual Cortex-M3 MPU subsystem |

28.8.6 PM Instrumentation (PMI)

The device takes advantage of the system trace infrastructure to provide visibility to the user about the major power management events. This is supported through a PMI module (PM profiler) instantiated in the PRM module. The PRM state changes are handled as generic events and encapsulated in STP hardware messages and exported through the MIPI-STM module. The nature of the PM events does not require accurate timestamping and thus, timestamping is handled at STM or trace receiver level.

The PM events are organized by class. Any PM state change from a specific class refreshes the entire instrumentation frame associated with that class. The STP message structure includes a PM event-ID indicating the class of the PM events.

The PM event classes supported are:

- Logic voltage domain OPP change
- Memory voltage domain OPP change
- Logic power domain state change
- Memory power domain state change

The PMI has a unique hardware master-ID assigned to it.

The PMI supports the possibility to report on activity in different event classes in the same sampling window. The user has the flexibility to size the capture sampling window.

Software events from the PM routines instrumentation can be interleaved with the PM hardware events. The user can take advantage of that feature to understand latencies for a specific power-management scenario or strategy.

28.8.7 CM Instrumentation (CMI)

The device instantiates two CMI modules (CM profilers), one in CM1 (CMI1), and one in CM2 (CMI2). The CMI1 and CMI2 modules are instantiations of the same debug-IP and can operate concurrently. Each of them has a separate unique hardware master-ID assigned to it.

The CM events profiling is similar to the PM instrumentation. Two exclusive instrumentation modes are supported:

- Clock activity:
 - Exposes to the user a snapshot of the state of all the clock domains derived from the same DPLL when CM detects a state change in the clock domain
 - Exposes to the user a snapshot of the DPLL settings when the CM signals a DPLL programming
- Module activity:
 - Exposes to the user periodically the active cycles count of the target modules
 - Exposes to the user periodically the active cycles count of the initiator modules

It provides visibility to the user about the state of the major clock domains along the application code execution. The STP message reports the effective state of the clock domain and therefore can highlight scenarios where a particular dependency is preventing the clock domain from being switched off.

The CM event classes supported are:

- Events capture mode – four classes:
 - Clock domain state
 - DPLL settings update
 - Clock frequency divider ratio
 - Clock source selection update
- Module activity collection mode – two classes:
 - Target module activity
 - Initiator module activity

When in events capture mode, the CMI supports the possibility of reporting on activity in different event classes in the same sampling window. The user has the flexibility to size the capture sampling window.

28.9 Concurrent Debug Modes

The debugger or application software can program the DRM to route a specific debug function to each device debug port pin.

Because of the limited number of pins allocated to debug, debug and trace source signals are multiplexed.

Table 28-27 summarizes the trace port configuration.

Table 28-27. Trace Port Configuration

| Pin Name | Internal Signal Name | I/O | Trigger | JTAG 20-Pin Header | TPIU PTM (ARM Trace) | | STM (System Trace) | | |
|-----------|----------------------|-----|-----------|--------------------|----------------------|---------------|--------------------|-------------|-------------|
| | | | | | 16-Bit Mode | 18-Bit Mode | Option 1 | Option 2 | Option 3 |

| dpm_emu10 | EMU10 | O | | | TRACEDATA[6] | TRACEDATA[8] | | | |
| dpm_emu9 | EMU9 | O | | | TRACEDATA[5] | TRACEDATA[7] | | | |
| dpm_emu8 | EMU8 | O | | | TRACEDATA[4] | TRACEDATA[6] | | | |
| dpm_emu7 | EMU7 | O | | | TRACEDATA[3] | TRACEDATA[5] | | | |
| dpm_emu6 | EMU6 | O | | | TRACEDATA[2] | TRACEDATA[4] | | | |
| dpm_emu5 | EMU5 | O | | | TRACEDATA[1] | TRACEDATA[3] | | | |
| dpm_emu4 | EMU4 | O | | | TRACEDATA[0] | TRACEDATA[2] | STM_DATA[3] | | |
| dpm_emu3 | EMU3 | O | | | TRACECTL | TRACECTL | STM_DATA[2] | | |
| dpm_emu2 | EMU2 | O | | | TRACECLK | TRACECLK | STM_CLK | | |
| dpm_emu1 | EMU1 | I/O | Trigger 1 | EMU1 | | TRACEDATA[1] | STM_DATA[1] | | STM_CLK |
| dpm_emu0 | EMU0 | I/O | Trigger 0 | EMU0 | | TRACEDATA[0] | STM_DATA[0] | | STM_DATA[0] |

NOTE: The configuration of the trace port must comply with Table 28-27; otherwise, it will be ignored by DRM hardware. For example, if Trigger0 is programmed on EMU10 and Trigger1 is programmed on EMU11, this configuration will be ignored.

Table 28-28 summarizes the concurrent debug and trace in the device.

Table 28-28. Concurrent Debug and Trace

| Debug Use Case | Concurrent Debug Flows | Debug Pins | Trace Pins | | |
|----------------|------------------------|------------|------------|---------|-------|
| | | Triggers | Data | Control | Clock |
| 0 | PTM | | 18 | 1 | 1 |
| | STM | | | | |
| | Triggers | | | | |
| 1 | PTM | | 16 | 1 | 1 |
| | STM | | | | |
| | Triggers | 2 | | | |
| 2 | PTM | | 16 | 1 | 1 |
| | STM | | 1 | – | 1 |
| | Triggers | | | | |
| 3 | PTM | | 8 | 1 | 1 |
| | STM | | 4 | – | 1 |
| | Triggers | 2 | | | |
| 4 | PTM | | 11 | 1 | 1 |
| | STM | | 4 | – | 1 |
| | Triggers | 2 | | | |

28.10 Memory Mapping

Table 28-29 summarizes the memory mapping of the debug modules.

Table 28-29. Debug Modules Memory Mapping

| Memory Space | Module Name | Start Address (hex) | End Address (hex) | Size |
|---------------------------------------------|---------------------------------------------------|---------------------|-------------------|-------|
| L3_EMU | MIPI-STM (256 × 4K channels) (address space 0) | 0x5400 0000 | 0x540F FFFF | 1MB |
| | MIPI-STM (256 × 1K channels) (address space 1) | 0x5410 0000 | 0x5413 FFFF | 256KB |
| | Cortex-A9 CPU0 debug/PMU | 0x5414 0000 | 0x5414 1FFF | 8KB |

⁽¹⁾ Embedded in Cortex-A9 MPU subsystem

⁽²⁾ Embedded in debug subsystem

⁽³⁾ Private memory access per Cortex-M3 core

Glossary

3

3D— Three Dimensional

3G— 3rd Generation of mobile communication systems

A

A/D— Analog to Digital Converter

ABB— Adaptive Body Bias

ABE— Audio Back End

ABEFW— Audio Back End Firewall

ACB— ac-bias frequency

ACBI— ac-bias line transitions per interrupt

ACE— ASIC Compiler Environment.

ACK— Acknowledge

ADC— Analog-to-Digital Converter/Conversion.

ADMA— Audio DMA

ADPLL— All Digital Phase Locked Loop. A closed loop frequency control system whose function is based on the phase-sensitive detection of the phase difference between the input signal and the output signal of the controlled oscillator (CO).

AE— Audio Engine. The AESS own processor.

AES— Advanced Encryption Standard

AESS— Audio Engine Subsystem

AEW— Auto Exposure and Auto White Balance

AF— Auto Focus

AFE— Analog Front End

AHB— Advanced High-performance Bus

ALE— Address Latch Enable

AMMU— Attribute Memory Management Unit

ANSI— American National Standards Institute

AP— Address Protection

APB— Advanced Peripheral Bus

- APE**— Application Engine
- API**— Application Programming Interface
- AR**— Automatic Reload
- ARGB**— Alpha Red Green Blue
- ARM**— Advanced RISC Machine
- ASCII**— American Standard Code for Information Interchange
- ASIC**— Application-Specific Integrated Circuit. A chip built for a particular application. In the context of this document, this refers to the FPGA that resides on the EVM board.
- ASP**— Application-Specific Peripheral
- ATA**— Interface standard for the connection of storage devices
- ATB**— AMBA Advanced Trace Bus
- ATC**— Audio Traffic Controller
- AVDAC**— Audio-Video DAC
- AVS**— Adaptive Voltage Scaling
- AWB**— Auto White Balance

B

- B**— Byte, 8 bits
- BAYER**— Bayer Filter mosaic. A color filter array (CFA) for arranging RGB color filters on a square grid of photosensors.
- BB**— Bus Busy
- BCD**— Binary-Coded Decimal.
- BCH**— Bose-Chaudhuri-Hocquenghem
- BE**— Big Endian.
- BGA**— Ball Grid Array
- BGAP**— Band Gap
- BIOS**— Built-In Operating System
- BIST**— Built-In Self-Test
- BL**— Buffer Logic
- BOF**— Beginning of Frame
- BPP**— Bits Per Pixel
- BS**— Block Synchronization
- BSC**— Boundary Scan Chain
- BSMEM**— Bit Stream Memory
- BTA**— Bus Turn Around
- BTE**— Burst Translation Engine

BW— Band Width

Bluetooth— A short-range radio technology aimed at simplifying communications among network devices and between devices and the Internet. It also aims to simplify data synchronization between network devices and other computers.

C

CABAC— Context-Adaptive Binary Arithmetic Coding

CALC3— Transform and Quantization Calculation Engine

CAS— Column Address Strobe

CAVLC— Context-Adaptive Variable Length Coder

CB— Copy Back

CBP— Coded Block Pattern

CBUFF— Circular Buffer

CCCR— Card Common Control Registers (SDIO)

CCP— Compact Camera Port

CDP— Coprocessor Data Operation

CDR— Clock Data Recovery

CE— Chip Enable

CEA-861-D— HDMI 1.3 video standard. It defines the video timing requirements, discovery structures, and data transfer structure.

CEC— Consumer Electronics Control

CFA— Color Filter Array

CH— Configuration Header. To use different settings than ROM Code defaults, that is, clock frequencies, SDRAM/DDRAM settings, GPMC settings if the customer wants.

CID— Card Identification Number

CIR— Consumer Infra Red

CLE— Command Latch Enable

CLK— Clock

CLUT— Color Look-Up Table

CM— Clock Management

CMEM— Coefficient Memory

CMOS— Complimentary Metal Oxide Semiconductor

CODEC— Coder/Decoder or Compression/Decompression. A device that codes in one direction of transmission and decodes in another direction of transmission.

CP15— Coprocessor 15. This coprocessor controls the operation and configuration of the TI925T.

CPR— Clock, Power, Reset

CPU— Central Processing Unit.

CRC— Cyclic Redundancy Check

CS— Chip-Select

CS-ETB— CoreSight Embedded Trace Buffer

CS-ETM— CoreSight Embedded Trace Macrocell

CS-TPIU— CoreSight Trace Port Interface Unit

CSI— Camera Serial Interface

CSW— Control Space Width

CSWR— Closed switch retention

CTM— Counter-Timer Module

CTRL— Control

CTS— Clear to Send

CVBS— Composite Video Broadcast Signal

ConnID— Connection Identifier. An Initiator Module Identifier. A ConnID is transmitted in-band with the request and is used for protection and error logging mechanism.

D

D2D— Die-to-Die

DAC— Digital to Analog Converter

DBB— Digital Baseband

DBI— Display Buffer Interface

DCD— Data Carrier Detect

DCO— Digitally Controlled Oscillator

DCS— Display Command Set

DCT— Discrete Cosine Transform.

DDC— Display Data Channel

DDMA— DSP Subsystem Direct Memory Access module

DDR— Double Data Rate

DE— Data Enable

DFF— Digital Flip-Flop

DFT— Design For Test

DI— Data In

DISPC— Display Controller

DL— Data Length

DLB— Data Loopback.

DLL— Delay-Locked Loop

DMA— Direct Memory Access.

DMC— Data Memory Controller

DMEM— Data Memory

DMIC— Digital Microphone Controller

DTM— Dynamic Memory Management

DNL— Differential nonlinearity. It describes the deviation between two analog values corresponding to adjacent input digital values for a DAC.

DO— Data Out

DPC— Defect Pixel Correction

DPCM— Differential Pulse Code Modulation

DPI— Display Parallel Interface

DPLL— Digital Phase-Locked Loop. Digital implementation of PLL.

DPS— Digital Power Switching

DRD— Dual-Role Device (a type of OTG USB device)

DRDY— Data Ready

DRM— Digital Rights Management

DRP— Digital Radio Processor

DSI— Display Serial Interface

DSP— Digital Signal Processor.

DSR— Data Set Ready

DSS— Display Sub-System. Also DISS

DT— Data Type

DTBC— Data Buffer Controller

DTCM— Data Tightly Coupled Memory

DTR— Data Transmit Ready

DVFS— Dynamic Voltage and Frequency Scaling

DVI— Digital Video Interface

E

EA— Enumeration Address

EAV— End of Active Video

ECC— Error Checking and Correction. Also Error Correction Code.

ECD3— Entropy Coder/Decoder

ED— Endpoint Descriptor

EFUSE— Electrical Fuse. A one-time programmable memory location usually set at the factory

EHCI— Enhanced Host Controller Interface

EMC— External Memory Controller

EMI— Electromagnetic interference
EMIF— External Memory Interface
EOB— End of Block
EOF— End of Frame
EOL— End of Line
EOT— End of Transfer
EPM— Emulation Pin Manager
ES— Erase Status
ETB— Embedded Trace Bus
ETM— Embedded Trace Macrocell

F

FAT— File Allocation Table
FCLK— Functional Clock
FCS— Frame Check Sequence
FD— Face Detect
FE— Framing Error.
FEC— Frame End Code
FF— Flip-Flop
FIFO— First In First Out.
FIQ— Fast Interrupt Request. See ISR.
FIR— Fast Infrared
FM— Frequency Modulate
FPS— Frame per Second
FROM— eFuse ROM
FS— Full-Speed
FSC— Frame Start Code. Also Frame Start Count.
FSM— Finite State Machine.
FSR— Fault Status Register
FV— Focus Value
FW— Firewall

G

GBC— Green Balance Correction
GDP— Generic Dot Product
GHB— Global History Buffer

GPIO— Genreal Purpose Input Output

GPMC— General Purpose Memory Controller

H

H.263— Video Codec Standart

H.264— Video Codec Standart

H/W— Hardware

HAL— Hardware Abstraction Layer

HBP— Horizontal Back Porch

HC— Host Controller

HD— High Definition

HDCP— High-bandwidth Digital Content Protection

HDMI— High-Definition Multimedia Interface

HDQ— Single-wire communication interface

HDTV— High-Definition Television

HFP— Horizontal Front Porch

HLOS— High-Level Operating System

HNP— Host Negotiation Protocol (OTG feature)

HPF— High-Pass Filter

HPI— Host Port Interface

HS— High-Speed

HSE— Horizontal Sync End

HSI— High Speed Synchronous Serial Interface

HSS— Horizontal Sync Start

HSSCLL— High-Speed Serial Control Channel

HSW— Horizontal Synchronization Pulse Width

HSYNC— Horizontal Synchronization.

HW— Hardware

HWA— Hardware Accelerators.

HWOBS— Hardware Observability

HWSEQ— Hardware Sequencer

I

I/F— Interface

I/O— Input/Output

I2C— Inter-Integrated Circuit.

- I2S**— Inter-IC Sound.
- IA**— Identifier Address
- ICE**— In-Circuit Emulation
- ICEPICK**— Generic TAP for emulation control
- ICLK**— Interface Clock
- ICONT**— Imaging Controller
- ICR**— Intersystem Communication Registers
- ID**— Identification
- IDCT**— Inverse Discrete Cosine Transform. See DCT.
- ILF3**— Improved Loop Filter engine
- IM**— Initiator Module. A module is an initiator whenever it is able to initiate read and write requests to the chip interconnect (typically: processors , DMA...).
- IME3**— Improved Motion Estimation engine
- IMX**— Image Extension coprocessor
- INL**— Integral Nonlinearity. It describes the maximum deviation between the ideal output of a DAC and the actual output level.
- INT**— Interrupt .
- INTC**— Interrupt Controller
- IP**— Intellectual Property
- IPC**— Interprocessor Communication. (also referred to as mailbox on occasion)
- IPE3**— Intra Prediction Estimation engine
- IPIPE**— Image Pipe
- IPIPEIF**— Image Pipe Interface
- IQ**— Inverse Quantization
- IR**— Incremental Redundancy Buffer
- IRQ**— Interrupt Request.
- ISA**— Instruction Set Architecture
- ISIF**— Image Sensor Interface
- ISP**— Image Signal Processor
- ISR**— Interrupt Service Routine.
- ISS**— Image SubSystem
- IST**— Interrupt Service Thread.
- ITCM**— Instruction Tightly Coupled Memory
- IV**— Initialization Vector
- IVA**— Image and Video Accelerator

IVA-HD— High Definition Image and Video Accelerator

IrDA— Infrared Data Association.

J

JEDEC— Joint Electronic Devices Engineering Council

JPEG— Joint Photographics Experts Group

JTAG— Joint Test Action Group.

K

KB— Kilobyte, 1024 B

KBD— Keyboard

Kbps— Kilobits per second

L

L1— Level 1 cache/memory

L2— Level 2 cache/memory

L3— First level of interconnect in OMAP platform

L4— Second level of interconnect in OMAP platform

LA— Logical Address

LAN— Local Area Network

LC— Logical Channel

LCD— Liquid Crystal Display.

LCM— Logical Channel to Memory

LCh— Logical DMA Channel. Also LCH

LDC— Load (from memory) to Coprocessor

LDC2— Lens Distortion Correction

LDM— Load Multiple

LDO— Low Dropout

LE— Little Endian.

LEC— Line End Code

LED— Light Emitting Diode.

LF— Loop Filter

LFB— Line-Fill-Buffer

LFN— Long File Name

LH— Local Host

LINK— Link Layer Device

LLP— Low-Level Protocol

LP— Low-Power, operation mode for PHY
LPCM— Linear Pulse Code Modulation
LPDDR— Low Power Double Data Rate
LPF— Loop Filter
LPM— Low-Power Mode
LPP— Lines Per Panel
LRB— Line-Read-Buffer
LS— Low-Speed
LSB— Least Significant Bit
LSC— Line Start Code
LSR— Linear Shift Register
LSW— Least Significant Word
LUT— Look-up Table

M

M2— Micro Memory
MAC— Message Authentication Code
MB— Megabyte, 1024 KB
MBAFF— MB-Level Adaptive Frame/Field
MBR— Master Boot Record
MC3— Motion Compensation Engine
MCSPi— Multichannel Serial Port Interface
MCU— Microcontroller Unit. Refers to the MPU.
ME— Motion Estimation
MEMIF— Memory Interface
MIF— Memory InterFace
MIPI— Mobile Industry Processor Interface
MIR— Medium Infrared
MJPEG— Motion JPEG
MMC— Multimedia Card
MMC/SD— Multimedia Card/SD
MMU— Memory Management Unit.
MP3— MPEG Layer 3.
MPEG— Motion Pictures Expert Group.
MPEG1— The first MPEG compression scheme specification.

MPU— Microprocessor Unit.
MS— Memory Stick
MSB— Most Significant Bit
MSGIF— Message Interface
Mb— Megabit
Mbps— Mega bits per second
McBSP— Multichannel Buffered Serial Port.
Modem— Modulator Demodulator

N

N/A— Not Applicable
NAC— Network Access Control
NAK— Not Acknowledged
NAND— NAND Flash memory.
NC— Not Connected
NIU— Network Interface Unit
NMI— Nonmaskable Interrupt. An interrupt that can be neither masked nor disabled.
NOP— No OPeration (DSP/CPU instruction)
NOR— A type of flash memory
NRZI— Non-Return-to-Zero Inverted
NSF— Noise Filter
NTSC— National Television System Committee. Television broadcast system.
NVB— Number of Valid Bytes
NVIC— Nested Vectored Interrupt Controller
NVM— Non-volatile Memory

O

OCM— On-chip Memory
OCMC— On-chip Memory Controller
OCP— Open-Core Protocol
OCPI— Open-Core Protocol Interface
OE— Output Enable
OHCI— Open Host Controller Interface. This is an industry standard USB Host Controller Interface.
OMAP— Open Multimedia Application Platform
ON2— Video Codec Standart
OPP— Operating Performance Point

- OS**— Operating System
- OSI**— (OSI model) Open Systems Interconnection Basic Reference Model
- OTG**— On-The-Go (USB 2.0 specification)

P

- PA**— Program Address
- PBIAS**— PMOS Bias transistor to provide the bias voltage to extended drain IOs
- PC**— Program Counter
- PCB**— Printed Circuit Board
- PCI**— Peripheral Component Interconnect.
- PCLK**— Pixel Clock
- PCM**— Pulse Code Modulation.
- PD**— Program Data
- PDA**— Personal Digital Assistant
- PDC**— Power-down Controller
- PDM**— Pulse Density Modulation
- PDU**— Protocol Data Unit
- PE**— Parity Error
- PF**— Packet Footer
- PFPW**— Prefetch and Prewrite posting engine
- PH**— Packet Header
- PHY**— Physical Layer Device
- PI**— Pixel Interpolation
- PID**— Protocol Identifier. The PID register is used in Windows CE mode only.
- PLL**— Phase-Locked Loop.
- PM**— Programming Model
- PMC**— Program Memory Controller
- PMEM**— Program Memory
- PMP**— Power Management Port
- POR**— Power-On Reset
- PPA**— Primary Protected Application.
- PPC**— Palm-size PC
- PPI**— Physical Layer Protocol Interface
- PPL**— Pixels per Line
- PRCM**— Power, Reset, Clock Management module

- PRM**— Power and Reset manager
- PS**— Packet Start
- PSC**— Prescaler Counter
- PSS**— Program Suspend Status
- PT**— Packet Type
- PTM**— Program Trace Macrocell
- PTV**— Prescale Clock Timer Value. Sets the value of the divisor used in scaling the clock.
- PU/PD**— Pull-Up / Pull-Down
- PWL**— Pulse Width Light (modulator). A 4096-bit randomsequence generator that provides control of the LCD backlighting and keypad.
- PWM**— Pulse Width Modulation
- PWR**— Power

Q

- QIQ**— Quantization and Inverse Quantization
- QMEM**— Quantizer Memory
- QMR**— Quantizer Matrix
- QVGA**— Quarter Video Graphics Array. One-fourth the resolution of VGA.

R

- R/W**— Read/Write. Also RW.
- R5**— Release 5 of 3GPP specifications on IMS and HSDPA standards
- R6**— Release 6 of 3GPP specifications on Wireless LAN networks, HSUPA, MBMS and enhancements to IMS standards
- RAM**— Random Access Memory. A memory element that can be written to, as well as read.
- RCA**— Relative Card Address
- RDR**— Receive Data Register
- RE**— Read Enable
- REQ**— Request
- RF**— Radio Frequency
- RFB**— Remote Frame Buffer
- RFBI**— Remote Frame Buffer Interface
- RFF**— Retention Flip-Flop
- RGB**— Red Green Blue
- RGBA**— Red Green Blue Alpha
- RI**— Ring Indicator
- RM**— Reed-Muller code

RO— Read Only

ROM— Read Only Memory. A semiconductor storage element containing permanent data that cannot be changed.

RST— Reset

RT— Real-Time

RTA— Retention Till Access

RTC— Real-Time Clock. A clock that keeps track of the time even when the device is turned off.

RTL— Register Transfer Level

RTOS— Real-Time Operating System

RTS— Request to Send

RVLC— Reversible Variable Length Coder

RX— Receive/Receiver

RXD— Receive Data

S

S/PDIF— Sony/Philips Digital Interface

S/W— Software

SAM— Signal Amplitude Modulation

SAR— Save and Restore. Hardware context saving for power saving.

SAV— Start of Active Video

SB— Silicon Backplane (Trade Mark)

SBC— Stream Buffer Controller

SCCB— Serial Camera Control Interface. 3-wire and 2-wire serial bus defined and deployed by Omnivision Technologies, Inc.

SCL— Serial Clock. Programmable serial clock used in the I2C interface. Also SCLK.

SCM— System Control Module

SCP— Serial Configuration Port

SCR— SDIO Configuration Registers

SCRM— System Clock and Reset Manager

SCTM— System Counter Timer Module

SCU— Snoop Control Unit

SD— SD card. A non-volatile memory card.

SDA— Serial Data. Serial data bus in the I2C interface.

SDHC— SD High Capacity card

SDIO— SD Input/Output

SDMA— System Direct Memory Access module

- SDP**— Software Development Platform
- SDR**— Single Data Rate
- SDRAM**— Synchronous Dynamic Random Access Memory
- SDRC**— SDRAM Controller.
- SE**— Safe Environment. Execution environment inside a device, which is protected against tampering
- SFL**— Subframe Length
- SGX**— Acronym for Graphics Accelerator
- SIM**— Subscriber Identity Module
- SIMCOP**— Still image coprocessor
- SIMD**— Single Instruction-Stream, Multiple Data-Stream
- SIR**— Slow Infrared
- SL2**— Shared Level 2 (memory/interface)
- SLM**— Static Leakage Management
- SLVS**— Scalable Low Voltage Signaling
- SMC**— Shared Message Channel
- SMEM**— Sample Memory
- SMI**— Safe Monitor Interrupt
- SMP**— Symmetric Multiprocessor Platform
- SMPS**— Switch Mode Power Supply
- SMSET**— Software Message and System Event Trace module
- SNR**— Signal-to-Noise Ratio
- SOC**— System-On-a-Chip
- SOF**— Start Of Frame
- SP**— Serial Port or Small Page
- SPI**— Serial Port Interface. A signaling protocol for exchanging serial data.
- SR**— SmartReflex
- SRAM**— Static Random Access Memory
- SRC**— Sample Rate Conversion
- SRG**— Sample Rate Generator
- SRP**— Session Request Protocol (OTG feature)
- SS**— Subsystem
- SSC**— Spread Spectrum Clocking
- SSI**— Serial Synchronous Interface
- ST**— Start Timer

- STC**— Store from Coprocessor (to memory) or System Time Clock, which is the master clock in an MPEG-2 encoder or decoder system.
- STM**— Synchronous Transfer Mode or Store Multiple.
- STN**— Super-Twist Nematic. A technique for improving LCD display screens by twisting light rays.
- SW**— Software
- SWI**— Software Interrupt
- SXGA**— Super eXtended Graphics Array
- SYSC**— System Control Module
- SmartReflex**— Dynamic voltage sensing module that generates the voltage error signal proportional to the difference in desired voltage and the current voltage

T

- TA**— Target Agent
- TAP**— Test Access Port
- TC**— Traffic Controller. Allows asynchronous operation among the external memory interface, the MPU, and the DSP.
- TCK**— Test Clock
- TCM**— Tightly Coupled Memory
- TD**— Transfer Descriptor
- TDI**— Test Data Input
- TDM**— Time Division Multiplex/Multiplexing
- TDO**— Test Data Output
- TFT**— Thin Film Transistor. A type of LCD flat panel display screen in which each pixel is controlled by one to four transistors.
- TI**— Texas Instruments
- TL**— Transmission Line
- TLB**— Translation Lookaside Buffer. A cache that contains entries for virtual-to-physical address translation and access permission checking.
- TLL**— Transceiver Less Link. This is logic which allows the user to connect two USB transceiver interfaces together directly without the use of differential transceivers.
- TM**— Target Module. A target module cannot generate read/write requests to the chip interconnects, but respond to these requests. However it may generate interrupts or DMA request to the system (typically: peripherals, memory controllers).
- TMDS**— Transition Minimized Differential Signaling. A technology for transmitting high-speed serial data and is used by the DVI and HDMI video interfaces.
- TMS**— Test Mode Select
- TOC**— Table of Contents
- TP**— Tiny Page
- TRM**— Technical Reference Manual

TRST— Test Reset

TRX— USB Transceiver. The USB analog driver/receiver.

TSHUT— Temperature Shutdown.

TTB— Translation Tabbe Base. It points to the base of a table in physical memory that contains section and page table descriptors.

TTH— Translation Table Hierarchy

TTL— Transistor Transistor Logic

TWL— Table Walking Logic

TX— Transmit/Transmitter

U

UART— Universal Asynchronous Receiver/Transmitter. Another name for the asynchronous serial port.

UE— Unrecoverable Error

UHS— Definition of SD cards with higher frequency

ULPI— UTMI+ Low Pin Interface (12-pin interface standard for connecting USB core logic to a USB transceiver)

ULPM— Ultralow-Power Mode

ULPS— Ultralow-Power State

UMC— Unified Memory Controller

USB— Universal Serial Bus. An external bus standard that supports data transfer rates of 12M bps (12 million bits per second). A single USB port can be used to connect up to 127 peripheral devices.

USSE— Universal Scalable Shader Engine

UTMI— USB 2.0 Transceiver Macrocell Interface

V

VA— Volt–Amps. A form of power management. A VA rating is the volts rating multiplied by the amps (current) rating, used to indicate the output capacity of an uninterruptible power supply (UPS) or other power source.

VBP— Vertical Back Porch

VC— Virtual Channel

VC-1— Video Codec Standart

VDMA— Video Direct Memory Access module

VENC— Video Encoder

VESA— Video Electronics Standards Association

VFP— Vertical Front Porch

VGA— Video Graphics Array. An industry standard for video cards.

VLC— Variable Length Decoder

VLCD— Variable Length Coding and Decoding coprocessor

VLCDJ— Variable-Length Coder/Decoder for JPEG

VLD— Variable Length Coder

VLIW— Very Long Instruction Word

VMODE— Bi-level voltage control interface

VP— Video Port

VRFB— Virtual Rotation Fixed Buffer

VS— Vertical Synchronization

VSE— Vertical Sync End

VSS— Vertical Sync Start

VSW— Vertical Synchronization Pulse Width

VSYNC— Vertical Synchronization. A bidirectional vertical timing signal occurring once per frame with a pulse-width defined as an integral number of lines (half-lines for interlaced mode). Also VS.

W

WB— Write Buffer

WC— Word Count

WD— Watchdog. A timer that requires the user program or OS periodically write to the count register before the counter underflows.

WDT— Watchdog Timer

WE— Write Enable

WFI— Wait For Interrupt

WNP— Write Non-Posted

WP— Write Protect

WSS— Wide-Screen Signaling

WT— Write Through

WTBU— Wireless Terminal Business Unit

WUGEN— Wake-Up Generator

Word16— 16 bits word

X

XGA— eXtended Graphics Array. Also XVGA.

XIP— eXecution In Place

Y

YUV— Luminance-Bandwidth-Chrominance

e

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, enhancements, improvements and other changes to its semiconductor products and services per JESD46, latest issue, and to discontinue any product or service per JESD48, latest issue. Buyers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All semiconductor products (also referred to herein as "components") are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its components to the specifications applicable at the time of sale, in accordance with the warranty in TI's terms and conditions of sale of semiconductor products. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by applicable law, testing of all parameters of each component is not necessarily performed.

TI assumes no liability for applications assistance or the design of Buyers' products. Buyers are responsible for their products and applications using TI components. To minimize the risks associated with Buyers' products and applications, Buyers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any patent right, copyright, mask work right, or other intellectual property right relating to any combination, machine, or process in which TI components or services are used. Information published by TI regarding third-party products or services does not constitute a license to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of significant portions of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI components or services with statements different from or beyond the parameters stated by TI for that component or service voids all express and any implied warranties for the associated TI component or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

Buyer acknowledges and agrees that it is solely responsible for compliance with all legal, regulatory and safety-related requirements concerning its products, and any use of TI components in its applications, notwithstanding any applications-related information or support that may be provided by TI. Buyer represents and agrees that it has all the necessary expertise to create and implement safeguards which anticipate dangerous consequences of failures, monitor failures and their consequences, lessen the likelihood of failures that might cause harm and take appropriate remedial actions. Buyer will fully indemnify TI and its representatives against any damages arising out of the use of any TI components in safety-critical applications.

In some cases, TI components may be promoted specifically to facilitate safety-related applications. With such components, TI's goal is to help enable customers to design and create their own end-product solutions that meet applicable functional safety standards and requirements. Nonetheless, such components are subject to these terms.

No TI components are authorized for use in FDA Class III (or similar life-critical medical equipment) unless authorized officers of the parties have executed a special agreement specifically governing such use.

Only those TI components which TI has specifically designated as military grade or "enhanced plastic" are designed and intended for use in military/aerospace applications or environments. Buyer acknowledges and agrees that any military or aerospace use of TI components which have **not** been so designated is solely at the Buyer's risk, and that Buyer is solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI has specifically designated certain components as meeting ISO/TS16949 requirements, mainly for automotive use. In any case of use of non-designated products, TI will not be responsible for any failure to meet ISO/TS16949.
