 - Compressed textures PVR-TC1, PVR-TC2, ETC1
 - Programmable support for all YUV formats
- Resolution support:
 - Frame buffer maximum size = 2048 x 2048
 - Texture maximum size = 2048 x 2048
- Texture filtering:
 - Bilinear, trilinear
 - Independent minimum and maximum control
- Antialiasing:
 - 4x multisampling
 - Programmable sample positions
- Indexed primitive list support
 - Bus mastered
- Programmable vertex DMA
- Render to texture:
 - Including twiddled formats
 - Auto MipMap generation
- Multiple on-chip render targets (MRTs)

NOTE: Performance is limited when on-chip memory is not available for the SGX core.

11.1.3 SGX Universal Scalable Shader Engine – Key Features

The USSE is the engine core of the POWERVR SGX architecture and supports a broad range of instructions.

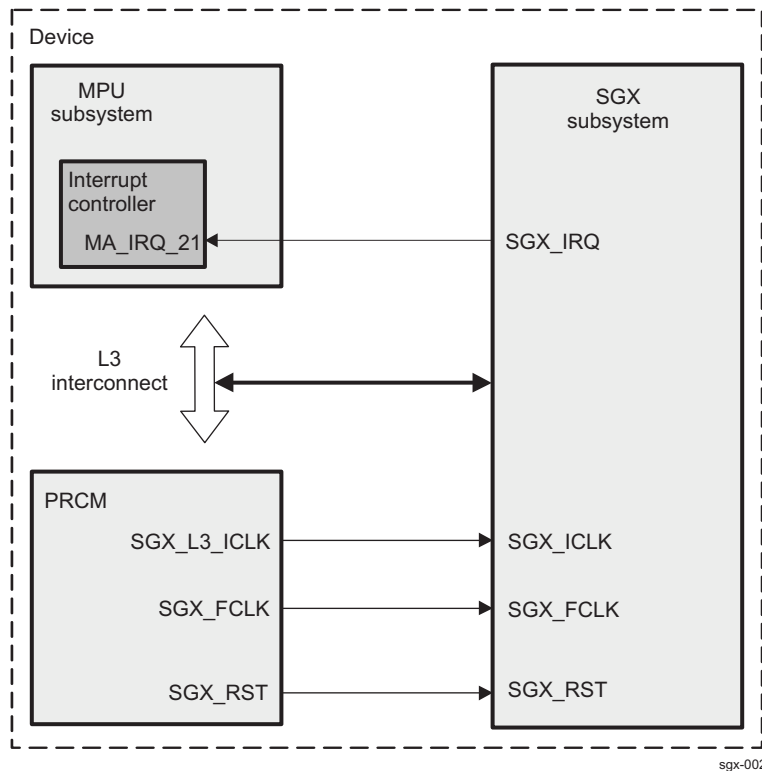

- Single programming model:
 - Multithreaded with 16 simultaneous execution threads and up to 64 simultaneous data instances
 - Zero-cost swapping in and out of threads
 - Cached program execution model
 - Dedicated pixel processing instructions
 - Dedicated vertex processing instructions
- SIMD execution unit supporting operations in:
 - 32-bit IEEE float
 - 2-way 16-bit fixed point
 - 4-way 8-bit integer
 - 32-bit bit-wise (logical only)
- Static and dynamic flow control:
 - Subroutine calls
 - Loops
 - Conditional branches
 - Zero-cost instruction predication
- Procedural geometry:
 - Allows generation of primitives
 - Effective geometry compression
 - High-order surface support
- External data access:
 - Permits reads from main memory using cache
 - Permits writes to main memory
 - Data fence facility
 - Dependent texture reads

11.2 SGX Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 11-2 shows SGX integration.

Figure 11-2. SGX Integration

The SGX subsystem is connected to the level 3 (L3) interconnect by a 128-bit master and a 64-bit slave interface.

Table 11-1 through Table 11-3 summarize the integration of the module in the device.

Table 11-1. Integration Attributes

| Module Instance | Attributes | |
|-----------------|--------------|--------------|
| | Power Domain | Interconnect |
| SGX | PD_GFX | L3 |

Table 11-2. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|----------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SGX | SGX_ICLK | SGX_L3_ICLK | PRCM | SGX interface clock |
| SGX | SGX_FCLK | SGX_FCLK | PRCM | SGX functional clock |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SGX | SGX_RST | SGX_RST | PRCM | SGX reset signal |

Table 11-3. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|----------------|--------------------------------------------------------------|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| SGX | SGX_IRQ | MA_IRQ_21 | Cortex-A9 INTC | SGX interrupt request to the MPU interrupt controller (INTC) |

NOTE:

- For a description of the interrupt source, see [Section 11.3.5, Interrupt Requests](#).
-

11.3 SGX Functional Description

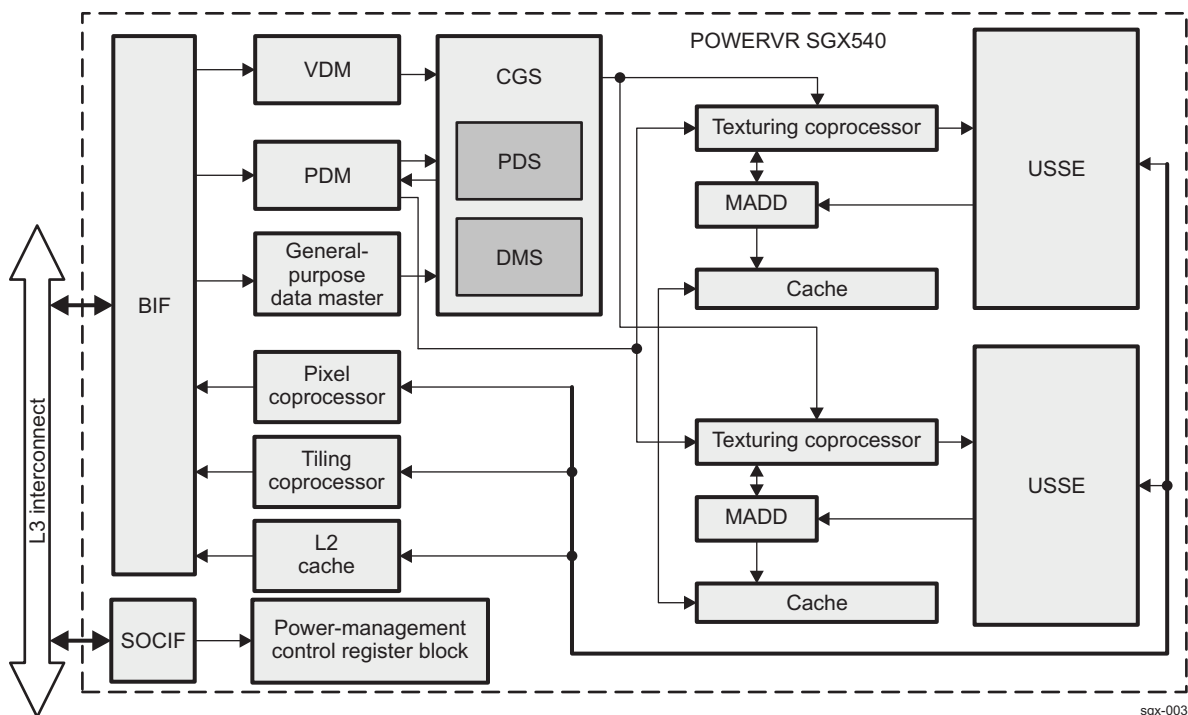

11.3.1 SGX Block Diagram

The SGX subsystem is based on the POWERVR SGX540 core from Imagination Technologies. The architecture uses both programmable and hard-coded pipelines to perform various processing tasks required in 2D, 3D, and video processing. The SGX architecture comprises the following elements:

- Coarse grain scheduler (CGS)
 - Programmable data sequencer (PDS)
 - Data master selector (DMS)
- Vertex data master (VDM)
- Pixel data master (PDM)
- General-purpose data master
- USSE
- Tiling coprocessor
- Pixel coprocessor
- Texturing coprocessor
- Multilevel cache

Figure 11-3 shows the SGX block diagram.

Figure 11-3. SGX Block Diagram

sgx-003

11.3.1.1 CGS

The CGS is the main system controller for the POWERVR SGX architecture and consists of two stages: the DMS and the PDS. The DMS processes requests from the data masters and determines which tasks can be executed given the resource requirements. The PDS then controls the loading and processing of data on the USSE.

11.3.1.2 Data Masters

The SGX core includes three data masters:

- **VDM:** the initiator of transform and lighting processing within the system. The VDM reads an input control stream, which contains triangle index data and state data. The state data indicates the PDS program, the size of the vertices, and the amount of USSE output buffer resource available to the VDM. The triangle data is parsed to determine unique indices that must be processed by the USSE. These are grouped together based on the configuration provided by the driver and presented to the DMS.
- **PDM:** the initiator of the rasterization processing within the system. Each pixel pipeline processes pixels for a different half of a given tile, which allows for optimum efficiency within each pipe due to the locality of the data. For each task it determines the amount of resource required within the USSE. It merges this with the state address and issues a request for execution on the USSE to the DMS.
- **General-purpose data master:** responds to events within the system (such as the end of a pass of triangles from the ISP, end of a tile from the ISP, end of a render, or parameter stream breakpoint event). Each event causes either an interrupt to the host or the synchronized execution of a program on the PDS. The program might or might not cause a subsequent task to be executed on the USSE.

11.3.1.3 USSE

The USSE is a user-programmable processing unit. Although general in nature, its instructions and features are optimized for three types of task: processing vertices (vertex shading), processing pixels (pixel shading), and video/imaging processing.

11.3.1.4 Multilevel Cache

The multilevel cache is a 2-level cache consisting of two modules: the main cache and the mux/arbiter/demux/decompression unit (MADD). The MADD is a wrapper around the main cache module designed to manage and format requests to and from the cache as well as provide level 0 caching for texture and USSE requests.

The MADD can accept requests from the PDS, USSE, and texture address generator modules. Arbitration is performed between the three data streams; any required texture decompression is also performed.

11.3.1.5 Texturing Coprocessor

The texturing coprocessor performs texture address generation and formatting of texture data. It receives requests from the iterators or the USSE modules and translates these into requests to the multilevel cache. Data returned from the cache are then formatted based on the texture format selected and sent to the USSE for pixel-shading operations.

11.3.1.6 Tiling Coprocessor

To process pixels in a tiled manner, the screen is divided into tiles and arranged as groups of tiles by the tiling coprocessor. An inherent advantage of tiling architecture is that a large amount of vertex data can be rejected at this stage, thus reducing both the memory storage requirements and the amount of pixel processing performed.

11.3.1.7 Pixel Coprocessor

The pixel coprocessor is the final stage of the pixel-processing pipeline and controls the format of the final pixel data sent to the memory. It supplies the USSE with an address to the output buffer, and the USSE returns the relevant pixel data. The address order is determined by the mode of the frame buffer. The pixel coprocessor contains a dithering and packing function.

11.3.2 SGX Clock Configuration

The SGX subsystem operates from two clocks: an interface clock (SGX_ICLK) and a functional clock (SGX_FCLK). The power, reset, and clock management (PRCM) module generates and distributes both clocks inside the device.

- The SGX_ICLK interface clock manages the data transfer on the L3 master and slave ports. The SGX_ICLK frequency is selected based on the whole device L3 interconnect clock frequency. For more information on the interface clock, see [Section 3.6.12, CD_SGX Clock Domains](#). When no longer required by the SGX subsystem, SGX_ICLK can be disabled by software at the PRCM level. For more information, see [Section 3.7.8, PD_SGX Description](#).

NOTE: SGX_ICLK is cut only if the SGX is ready to go into IDLE state.

- SGX_FCLK is the functional clock and is used inside the SGX subsystem to generate clock signals to multiple SGX clock domains. Depending on the clock source selection and the DPLL settings, SGX_FCLK can support a frequency of up to 307 MHz. The SGX_FCLK clock is provided by either the PRCM module or the peripheral DPLL, as described in [Section 3.6.12, CD_SGX Clock Domains](#). Selection is made at the PRCM level. When no longer needed by the SGX subsystem, SGX_FCLK can be cut by software at the PRCM level, if the module is ready to enter the IDLE state. For more information, see [Section 3.7.8, PD_SGX Description](#).

11.3.3 SGX Software Reset

The SGX subsystem has its own reset domain. Global reset of the SGX is performed by activating the SGX_RST signal in the SGX_RST domain.

NOTE: The APIs delivered with the SGX provide a software reset functionally equivalent to a hardware reset.

11.3.4 SGX Power Management

The SGX subsystem has its own power domain (SGX power domain). For additional information about the SGX power domain, see [Section 3.7.8, PD_SGX Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: The SGX handles automatic clock gating performed on the multiple internal module clock domains.

In addition, software-controlled clock gating is managed inside the SGX and handled by the related API delivered with the module.

11.3.5 SGX Interrupt Requests

The SGX subsystem can generate one interrupt signal to the MPU INTC mapped to SGX_IRQ.

11.4 SGX Register Manual

CAUTION

All SGX registers are limited to 32-bit data accesses; 8- and 16-bit accesses are not allowed because they can corrupt register content.

Audio Back End

This chapter describes the audio back end (ABE) module.

| Topic | Page |
|--------------------------------|-------------|
| 12.1 ABE Overview | 3000 |

12.1 ABE Overview

The audio back end (ABE) module is a subsystem that manages various audio and voice uplink and downlink streams between the initiator (the Cortex™-A9 microprocessor unit [MPU], digital signal processor [DSP], or direct memory access [DMA] controller) and the peripheral physical interfaces (multichannel buffered serial port [McBSP], SLIMbus®, digital microcontroller [DMIC], multichannel pulse density modulation [McPDM], and multichannel audio serial port [McASP]).

The ABE module handles the audio processing for the applications. It receives voice or audio samples from the initiator or the external audio chip (TWL6040 or other) and sends them to the peripheral interfaces or memories after processing. The ABE can perform buffering of audio samples, mix audio with a voice down stream and/or a microphone up stream (sidetone), and can apply some post-processing.

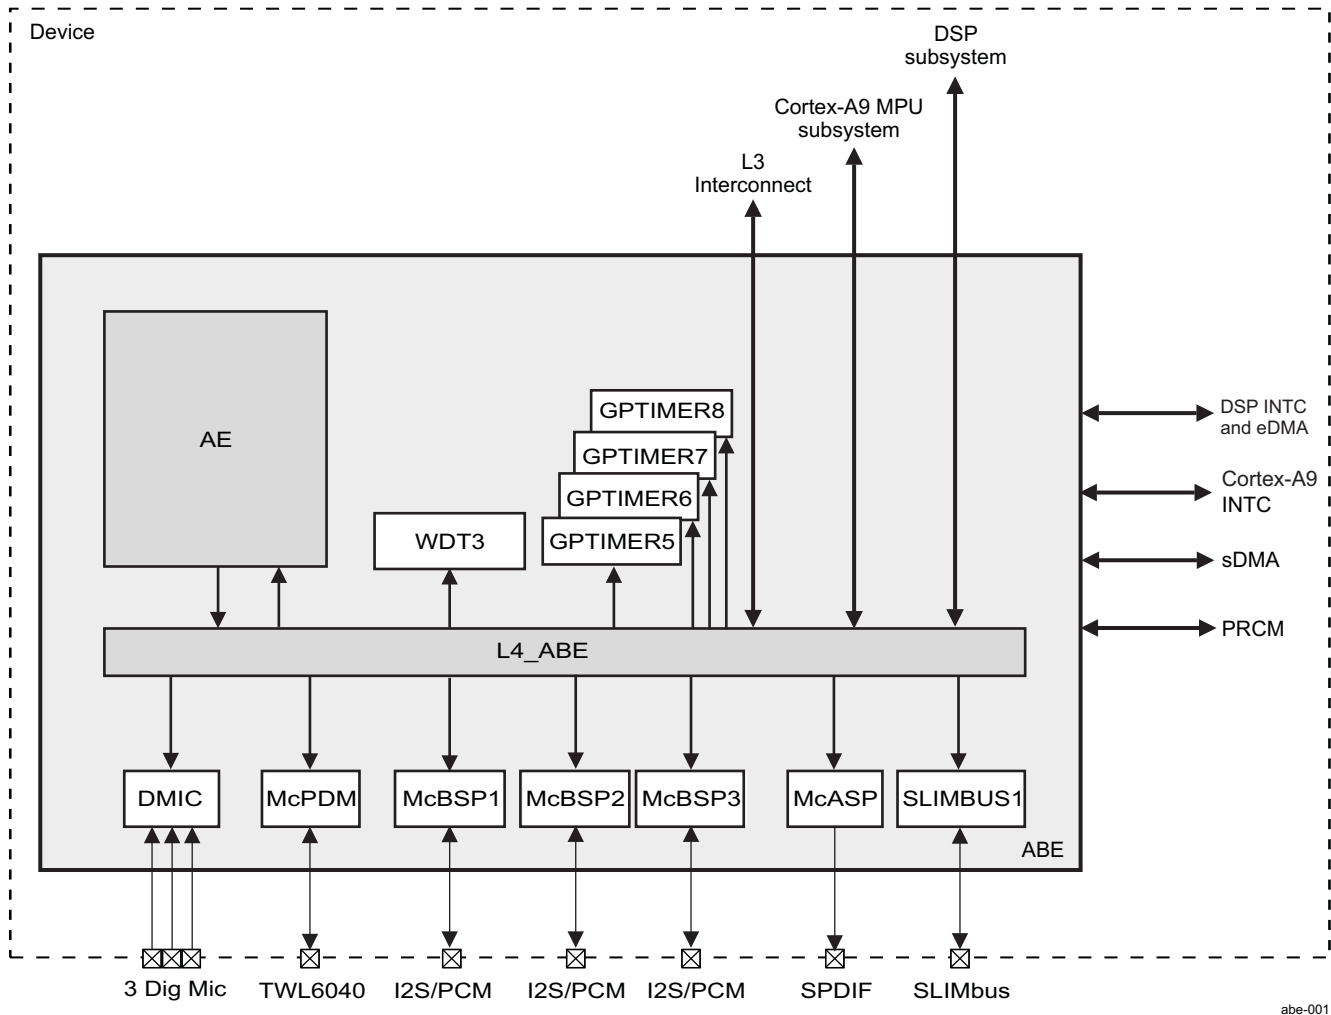

The ABE integrates the following modules:

- Peripheral physical interfaces:
 - Three McBSP modules
 - One McASP module
 - One mobile industry processor interface (MIPI) SLIMbus interface
 - One DMIC module to support up to six mono and up to three stereo digital microphones
 - One MCPDM module to support interconnect with an external audio chip.
- Audio engine (AE):
 - Performs real-time signal processing like sample rate conversion, filtering, equalizing, and side-tone
 - Audio traffic controller (ATC):
 - Performs data move in the ABE
 - Generates interrupt requests to the DSP and Cortex-A9 interrupt controllers
 - On-chip memory:
 - 64KB of RAM; 32-bit data memory (DMEM)
 - 6KB for coefficient memory RAM (CMEM)
 - 18KB for sample memory RAM (SMEM)
- Local L4 interconnect (L4_ABE) to:
 - L3 interconnect
 - Cortex-A9 MPU
 - DSP

The Cortex-A9 MPU and the DSP have private access to the L4_ABE interconnect. All other initiators (sDMA) can access the L4_ABE only through the L3 interconnect.
- Timers:
 - Four general-purpose (GP) timers
 - One watchdog timer
- Clock and reset management: Receives clock and reset signals from the device PRCM module. The audio engine operates from the DPLL_ABE, which is in the PRCM module. The ABE modules can be supplied with clock signals from the DPLL_ABE or the DPLL_PER. The ABE has its own hardware reset domain (AUDIO_RST).
- Power management: The ABE module is power-independent. It has its own dedicated power domain (PD_ABE) and can execute audio processing with the rest of the device in retention or in off mode.
- Each peripheral in the ABE can be accessed directly by the initiator when the AE is bypassed (legacy mode, for old software compatibility).

Figure 12-1 is a high-level overview of the ABE.

Figure 12-1. Audio Back End

abe-001

12.1.1 AE Subsystem

The AE is the core of the ABE subsystem. It performs the real-time audio processing within the ABE: mixing, muxing, volume control, smooth muting, sampling rate conversion, and side-tone equalization. The AE subsystem also processes and executes all data transfers. To optimize the global processing, the ATC moves the data. An IRQ/DMA controller controls system IRQ and DMA requests. Input DMA requests come from the ABE peripherals, and output DMA requests and IRQ are generated and sent to the system (Cortex-A9 MPU interrupt controller, DSP interrupt controller, system DMA [sDMA], and the DSP enhanced direct memory access controller [eDMA]).

The AE subsystem contains:

- AE: processes the sample in SMEM with help of CMEM.
 - SMEM
 - CMEM
- DMEM contains the audio buffer and communication circular buffer.
- ATC: Transfers data between all modules in the ABE
- IRQ DMA controller

For more information about the audio engine, see the *Hardware Abstraction Layer (HAL) Addendum*.

12.1.2 Local Audio Interconnect

The ABE has its own audio local interconnect (L4_ABE), which interconnects and manages the data flow among all ABE modules.

L4_ABE main features are:

- Initiator ports: Cortex-A9 MPU, DSP, L3 interconnect, and AE subsystem. The sDMA operates with the L4_ABE interconnect through the L3 interconnect initiator port. The eDMA operates with the L4_ABE interconnect through the DSP initiator port.
- Target ports: AE subsystem, McBSP1/2/3, DMIC, McPDM, McASP, GPTIMER5/6/7/8, WDT3, and SLIMBUS1
- 8-, 16-, or 32-bit data, single access
- 4-bit x 32-bit initiator ports for each interconnect instance
- Auto clock-gating feature
- Little-endian transaction assumed for all packing/unpacking operations
- Nonblocking architecture with fair arbitration between threads
- Target interconnect interfaces support fully synchronous and divided synchronous accesses.

For more information, see [Chapter 13, Interconnect](#).

12.1.3 GP Timers

The ABE embeds four GP timers: GPTIMER5 through GPTIMER8. All GP timers have interrupts connected to the Cortex-A9 MPU, DSP, and AE subsystems.

GP timer controllers have the following functions:

- Interconnect slave interface (L4) supports:
 - 32-bit data bus width
 - 16-/32-bit access supported
 - 10-bit address bus width
 - Burst not supported
 - WNP (Write-Non-Posted) supported
- Interrupts generated on overflow, compare, and capture
- Free-running 32-bit upward counter
- Supported modes:
 - Compare and capture modes
 - Auto-reload mode
 - Start-stop mode
- Programmable divider clock source
- Dedicated input trigger for capture mode and dedicated OUT trigger/PWM signal
- On-the-fly read/write register
- Supports disconnect protocol

For more information, see [Section 22.2, General-Purpose Timers](#).

12.1.4 Watchdog Timer

The ABE embeds one watchdog timer, WDT3, that generates an interrupt condition to the Cortex-A9 MPU on overflow, which can be used by the application software through the PRCM module to indirectly trigger a global warm reset.

WDT3 main features are:

- Interconnect slave interface (L4) supports:
 - 32-bit data bus width

- 16- and 32-bit access supported
- 11-bit address bus width
- Burst not supported
- WNP supported
- Free-running 32-bit upward counter
- Programmable divider clock source
- Watchdog is reset on power up or after a warm reset and then starts counting.
- Reset or interrupt actions on a timer overflow condition and according to the watchdog timer source
- Support of disconnect protocol

For more information, see [Section 22.3](#), *Watchdog Timers*.

12.1.5 **Digital Microphone Controller**

The DMIC allows support of up to three digital stereo microphones that send it a pulse-density modulated stream of bits, transferred on one period or one half-period of the clock (over-sampling clock) provided to the DMIC. Each microphone is directly connected to the TX filter decimator to extract the audio samples with a maximum OF 96 db SNR with a frequency sampling set to 96 kHz.

The DMIC has the following features:

- Six external pin connections (three data lines and three clock lines)
- Delivers one common clock (on the three clock lines) for all digital microphones
- Supports idle request/acknowledge protocol
- Supports stereo and mono digital microphones (up to three)
- Rising or falling edge configuration for the clock signal sampling
- DMIC-clock-programmable
- Interconnect slave interface (internal interconnect) supports 32-bit data bus width.
- One DMA request capability on a programmable FIFO threshold
- One RX FIFO (16-bit x 24-bit word depth) per microphone
- Complies with PRCM interrupts to the Cortex-A9 MPU and DSP subsystems
- Interconnect sample format: 32 bits (only 24 are significant)
- Supports idle request/acknowledge PRCM protocol

For more information, see [Section 23.7](#), *DMIC*.

12.1.6 **SLIMbus**

There is one SLIMbus module instantiation inside the ABE, SLIMbus1. The SLIMbus controller provides a bidirectional, multidrop, multichannel 2-line serial interface between the ABE and up to seven off-chip components in a system such as an audio codec, a Bluetooth® module, or an FM radio receiver/transmitter. Because of its versatility, SLIMbus can accommodate a wide range of peripherals and clocked frame-oriented protocols (I2S, pulse code modulation [PCM], time division multiplexing [TDM]).

SLIMbus has the following features:

- Supports idle request/acknowledge PRCM protocol
- Complies with MIPI SLIMbus standard version 1.0
- Interconnect slave interface (L4) supports:
 - 32-bit data bus width
 - 8-, 16-, and 32-bit access supported
 - 11-bit address bus width
 - Burst not supported
 - WNP supported
- Support of seven SLIMbus devices:

- One manager
- One framer
- One interface
- Four generic
- Message protocol partially implemented in SLIMbus module hardware:
 - Information elements are not stored in the module.
 - Message interpretation is not processed in the module.
 - FIFO size: 32 bytes for TX, 32 bytes for RX
- Support for eight TX and eight RX independent ports (data channels):
 - Supported transport protocols: Isochronous, pulled, pushed, asynchronous
 - Programmable segment data length (sample size) from 8 to 32 bits (8, 12, 16, 20, 24, 28, 32), including DATA and AUX
 - Programmable FIFO sizes
 - Programmable port assignment to any of the four generic devices
 - One DMA request line per port
- Operating frequencies of 0 to 24.576 MHz
- Supports disconnect protocol

For more information, see [Section 23.9](#), *Serial Low-Power Inter-Chip Media Bus Controller*.

12.1.7 Multichannel Audio Serial Port

The multichannel audio serial port (McASP) is a GP audio serial port. It is useful for intercomponent (DIT) transmission. The McASP is intended to be flexible enough so that it may connect gluelessly to audio A/D, D/A, CODEC and SPDIF transmit physical layer components.

McASP has the following features:

- 2-interconnect slave interface supports:
 - One interconnect configuration slave interface
 - One interconnect DMA slave interface
 - 32-bit data bus width
 - 16- and 32-bit access
 - 10-bit address bus width
 - Burst not supported
 - WNP
- Supports idle request/acknowledge protocol
- Buffers for transmit/receive operations
- DMA requests (one per direction) link with the 32-bit register
- Up to four transmit channels
- Four serializers implemented
- Support of disconnect protocol

For more information, see [Section 23.8](#), *McASP*.

12.1.8 Multichannel Buffered Serial Port

There are three McBSP instantiations: McBSP1 through McBSP3. They provide a full-duplex direct serial interface between the ABE and external devices, such as other modems, BT chips, or codecs. Because of its versatility, a McBSP can accommodate a wide range of peripherals and clocked frame-oriented protocols (I2S, PCM, TDM).

List of recommended usage per McBSP:

- MCBSP1: BT voice/audio data
- MCBSP2: Digital baseband (DBB) voice data
- MCBSP3: MIDI FM data

The McBSP has the following features:

- Interconnect slave interface (internal interconnect) supports:
 - 32-bit data bus width
 - 8-, 16-, and 32-bit access
 - 10-bit address bus width
 - Burst not supported
 - WNP
- Buffers for transmit/receive operations: 128/128 32-bit words (McBSP1, 2, 3)
- Interrupts configurable in legacy mode (two requests) or PRCM-compliant (one request)
- DMA requests (one per direction) triggered with programmable FIFO thresholds
- Multidrop support
- Serial interface description
- Four-pin configuration (McBSP1, 2, 3)
- Full-duplex communication
- Multichannel selection modes
- Support to enable or block transfers in each channel
- Up to 128 channels for transmission and for reception
- Supported protocols
- Direct interface to industry-standard codecs, analog interface chips (AICs), and other serially connected A/D and D/A devices:
 - I2S-compliant devices
 - TDM bus devices
 - PCM devices
- A wide selection of data sizes: 8, 12, 16, 20, 24, and 32 bits
- Supports idle request/acknowledge protocol
- Clock generation support:
 - Independent clocking and framing for reception and for transmission up to 48 MHz
 - Support for external generation of clock signals and frame-synchronization (frame-sync) signals
 - A programmable sample rate generator for internal generation and control of clock signals and frame-sync signals
- Support of disconnect protocol

For a complete description, see [Section 23.5](#), *Multichannel Buffered Serial Port*.

12.1.9 Multichannel Pulse Density Modulation Module

The McPDM is a proprietary interface based on multichannel pulse density modulation. The module consists of five downlinks and three uplinks. Two other uplink channels are reserved for status communication.

The McPDM has the following features:

- Interconnect slave interface (L4_ABE internal interconnect) supports:
 - 32-bit data bus width
 - 10-bit address bus width
 - Burst not supported
 - WNP

- Full-duplex communication:
 - Five audio downstream channels
 - three audio upstream channels
- RX/TX FIFO operations: 32-bit words per channels
- Complies with PRCM interrupts:
 - One to the MPU subsystem
 - One to the DSP subsystem
- DMA requests (one per direction) triggered with programmable FIFO thresholds; depending on the FIFO implementation, one per channel or one per direction
- Decimation filter for embedded uplink paths (five paths if two status paths)
- Oversampling for embedded uplinks (five paths)
- Sigma delta for embedded downlinks (three paths)
- Deserializers for the two status upstream channels
- Support of disconnect protocol

For more information, see [Section 23.6](#), *Multichannel PDM Controller*.

Interconnect

This chapter describes the device interconnect.

NOTE: The L3 interconnect is instantiation of the NoC interconnect from Arteris, Inc. Arteris is a registered trademark of Arteris, Inc.

| 13.2 L3 Interconnect | 3016 |
| 13.3 L4 Interconnects | 3131 |

13.1 Interconnect Overview

13.1.1 Terminology

The following terminology is critical to understanding the interconnect:

- **Initiator:** Module able to initiate read and write requests to the chip interconnect (typically: processors, DMA, etc.).
- **Target:** Unlike an initiator, a target module cannot generate read/write requests to the chip interconnect, but it can respond to these requests. However, it may generate interrupts or a DMA request to the system (typically: peripherals, memory controllers).

NOTE: A module can have several separate ports; therefore, a module can be an initiator and a target.

- **Agent:** Each connection of one module to one interconnect is done using an agent, which is an adaptation (sometimes configurable) between the module and the interconnect. A target module is connected by a target agent (TA), and an initiator module is connected by an initiator agent (IA).
- **Interconnect:** The decoding, routing, and arbitration logic that enables the connection between multiple initiator modules and multiple target modules connected on it.
- **Register target (RT):** Special TA used to access the interconnect internal configuration registers
- **Data-flow signal:** Any signal that is part of a clearly identified transfer or data flow (typically: command, address, byte enables, etc.). Signal behavior is defined by the protocol semantics.
- **Sideband signal:** Any signal whose behavior is not associated to a precise transaction or data flow.
- **Out-of-band error:** Any signal whose behavior is associated to a device error-reporting scheme, as opposed to in-band errors.

NOTE: Interrupt requests and DMA requests are not routed by the interconnect in the device.

- **Firewall:** A programmable feature integrated in a TA or L4 interconnect to prevent unauthorized access to or from a module. A firewall can be configured using three criteria:
 - Initiator requesting access
 - Address space access
 - Type of access
- **ConnID:** Any transaction in the system interconnect is tagged by an in-band qualifier ConnID, which uniquely identifies the initiator at a given interconnect point. A ConnID is transmitted in band with the request and is used for firewall and error-logging mechanism.
- **Firewall comparison mechanism:** A comparison made in the firewall between access in-band qualifiers and access permissions that are programmed in the firewall configuration registers. If the comparison is successful, access is allowed; otherwise, access is denied.
- **MCcmd qualifier:** Command bus that indicates the type of transfer requested. [Table 13-1](#) lists the commands encoded. For information specific to L3 Interconnect Error Logging, see [Table 13-26](#)

Table 13-1. MCcmd Qualifier Description

| MCcmd[2:0] | Transaction Type |
|------------|------------------|
| 0 0 0 | Idle |
| 0 0 1 | Write |
| 0 1 0 | Read |
| 0 1 1 | ReadEx |
| 1 0 0 | Not used |
| 1 0 1 | Write nonposted |
| 1 1 0 | Not used |
| 1 1 1 | Not used |

- MReqInfo qualifier: Three MReqInfo qualifiers describe the access during the use of the firewall comparison mechanism, as described in [Table 13-2](#).

Table 13-2. MReqInfo Qualifier Description

| Qualifiers | Description |
|----------------|----------------------|
| MReqType | 0: Data access |
| | 1: Opcode fetch |
| MReqSupervisor | 0: User mode |
| | 1: Supervisor mode |
| MReqDebug | 0: Functional access |
| | 1: Debug access |

- Register that configures the combination of the MReqInfo, allowing access permission to the TM based on the MReqInfo in-band qualifier values.
- SError: Target that indicates an error condition to the initiator.
- SResp qualifier: Response from the target to the initiator concerning the transaction, as described in [Table 13-3](#).

Table 13-3. SResp Qualifier Description

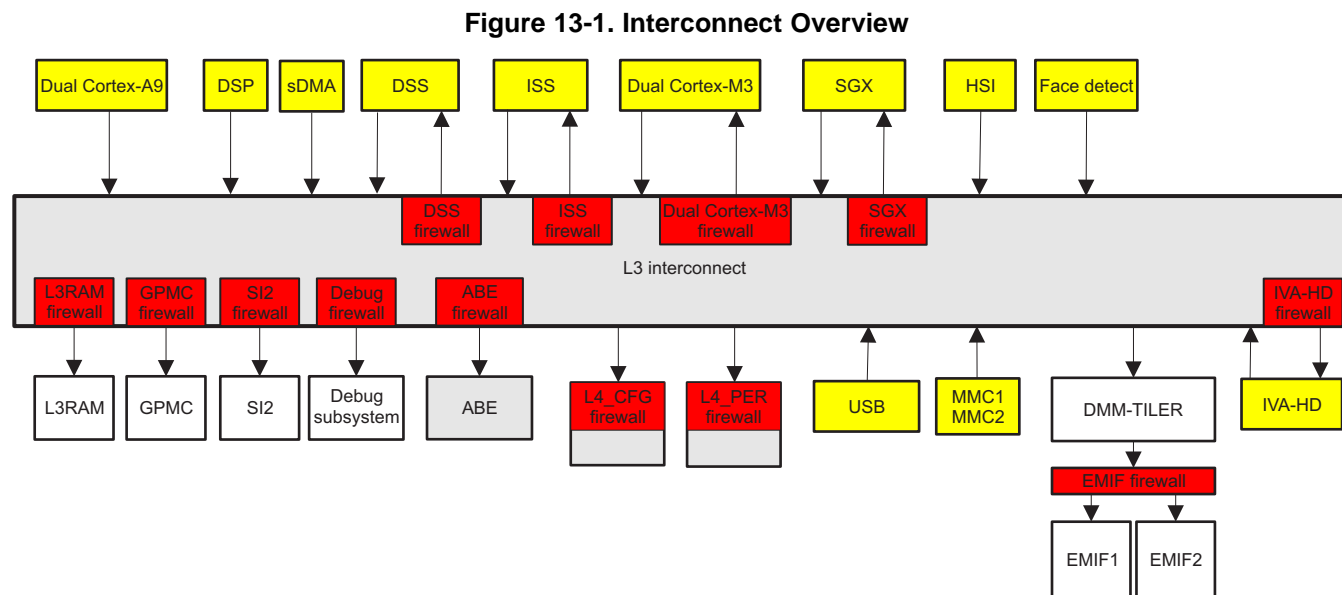

| SResp[1:0] | Description |
|------------|-------------------|
| 0 0 | No response |
| 0 1 | Data valid/accept |
| 1 0 | Not used |
| 1 1 | Error |

13.1.2 Architecture Overview

The device memory hierarchy includes four levels:

- Level 1 (L1) is internal to the central processing units (CPUs). It concerns data exchange with the internal Level1 cache memory subsystem, and it is the closest memory to the microprocessor unit (MPU) core and the IVAHD core.
- Level 2 (L2) is included in the IVAHD subsystem and the MPU subsystem.
- The chip-level interconnect consists of one level 3 (L3) interconnect and four level 4 (L4) interconnects. It enables communication among the modules and subsystems in the device.

Figure 13-1 shows an overview of the L3 and L4 interconnect architecture.

- L3 handles many types of data transfers, especially exchanges with system-on-chip (SoC)/external memories. L3 transfers data with a maximum width of 128 bits from the initiator to the target. The L3 interconnect is a little-endian platform.
- The L4 is composed of the following:
 - L4_CFG: Includes the majority of the configuration interface for L3 system modules and peripheral interconnect; L4_PER: Includes the main peripherals that require system direct memory access (sDMA) access.
 - L4_WKUP: Includes peripherals attached to the WKUP power domain.

Modules are connected to the interconnect through an IA for the initiator module and a TA for target modules. Each module/subsystem connection is statically configured to tune the access, depending on the characteristics of the module.

To unauthorize a module or L4 interconnect access, some TAs include configurable firewalls (FWs). A firewall restricts or filters the accesses allowed to an initiator according to different access criteria. The firewalls can usually be configured by software.

The L3 and L4 interconnect default settings are fully functional; they enable all possible functional data paths and a minimal default protection setting. However, the interconnect parameters can be modified to fit user expectations.

13.1.3 Module Distribution

IAs and TAs provide the interface to connect the different modules and the interconnect.

Table 13-4 through Table 13-11 list the device modules, subsystems, and associated agents. The agents are listed for each interconnect domain:

- L3 initiator (master network interface units [NIUs] – MN) and target (slave NIUs – SN) agents
- L4_PER initiator and target agents
- L4_CFG initiator and target agents
- L4_WKUP initiator and target agents

13.1.3.1 L3 Interconnect Module Distribution

Table 13-4 and Table 13-5 list the IAs and TAs, respectively, of the L3 interconnect.

Table 13-4. Master NIUs

| Master NIU Name | Description |
|------------------|----------------------------------------------------|
| L3_MN_CORTEXA9 | Cortex™-A9 microprocessor unit subsystem |
| L3_MN_DSP | DSP subsystem |
| L3_MN_DSS | Display subsystem |
| L3_MN_MMC1/2 | Multimedia controller |
| L3_MN_IVAHD | Video accelerator subsystem |
| L3_MN_SGX | Graphic accelerator |
| L3_MN_ISS | Imaging accelerator subsystem |
| L3_MN_CORTEXM3 | Cortex™-M3 microprocessor subsystem |
| L3_MN_FACEDETECT | Face detection module |
| L3_MN_SDMA_rd | System DMA |
| L3_MN_SDMA_wr | System DMA |
| L3_MN_HSI | High-speed synchronous serial interface controller |
| L3_MN_FSUSB | Full-speed USB host controller |
| L3_MN_HSUSBOTG | High-speed (HS) on-the-go (OTG) USB controller |
| L3_MN_HSUSBHOST | Multiport USB host controller |
| L3_MN_DAP | JTAG®/emulation access to system resources |

Table 13-5. Slave NIUs

| Slave NIU Name | Description |
|----------------|------------------------------------------|
| L3_SN_OCM_RAM | On-chip memory controller |
| L3_SN_GPMC | General-purpose memory controller (GPMC) |
| L3_SN_DMM1 | Dynamic memory management |
| L3_SN_DMM2 | Dynamic memory management |
| L3_SN_SGX | Graphic accelerator |

Table 13-5. Slave NIUs (continued)

| Slave NIU Name | Description |
|---------------------|-------------------------------------------|
| L3_SN_ISS | Imaging accelerator subsystem |
| L3_SN_IVAHD_CFG | Video accelerator subsystem configuration |
| L3_SN_IVAHD_SL2 | Video accelerator subsystem shared memory |
| L3_SN_DSP | DSP subsystem |
| L3_SN_CORTEXM3 | Cortex-M3 MPU subsystem |
| L3_SN_DSS | Display subsystem |
| L3 interconnect | L3 internal registers |
| L3_SN_ABE | Audio back end |
| L3_SN_L4_CFG | L4 interconnect configuration |
| L3_SN_L4_PER0/1/2/3 | L4 interconnect peripherals |
| L3_SN_L4_EMU | L4 interconnect EMU subsystem |

13.1.3.2 L4 Interconnect Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

[Table 13-6](#) through [Table 13-11](#) list all modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

13.1.3.2.1 L4_PER Interconnect Agents

The L4_PER interconnect handles transfers only to peripherals in the PER power domain. [Table 13-6](#) lists the PER TAs.

Table 13-6. L4_PER TAs

| Module Target Name | Description |
|--------------------|------------------------------------------------------------------|
| PER_TA_UART1 | Universal asynchronous receiver transmitter (UART) port 1 module |
| PER_TA_UART2 | UART port 2 module |
| PER_TA_UART3 | UART port 3 module |
| PER_TA_UART4 | UART port 4 module |
| PER_TA_GPTIMER2 | General-purpose timer 2 (GPTIMER2) module |
| PER_TA_GPTIMER3 | GPTIMER3 module |
| PER_TA_GPTIMER4 | GPTIMER4 module |
| PER_TA_GPTIMER9 | GPTIMER9 module |
| PER_TA_GPTIMER10 | GPTIMER10 module |
| PER_TA_GPTIMER11 | GPTIMER11 module |
| PER_TA_DSS | Display subsystem configuration module |
| PER_TA_GPIO2 | General-purpose input/output 2 (GPIO2) module |
| PER_TA_GPIO3 | GPIO3 module |
| PER_TA_GPIO4 | GPIO4 module |
| PER_TA_GPIO5 | GPIO5 module |
| PER_TA_GPIO6 | GPIO6 module |
| PER_TA_I2C1 | Multimaster inter-integrated circuit 1 (I2C1) module |
| PER_TA_I2C2 | Multimaster I2C2 module |
| PER_TA_I2C3 | Multimaster I2C3 module |
| PER_TA_I2C4 | Multimaster I2C4 module |
| PER_TA_SLIMBUS2 | Silmbus 2 module |
| PER_TA_ELM | Error location module |

Table 13-6. L4_PER TAs (continued)

| Module Target Name | Description |
|--------------------|------------------------------------------------------------|
| PER_TA_MCBSP4 | Multichannel buffered serial port 4 (McBSP4) module |
| PER_TA_MCSP1 | Multichannel serial peripheral interface 1 (McBSP1) module |
| PER_TA_MCSP2 | McSPI2 module |
| PER_TA_MCSP3 | McSPI3 module |
| PER_TA_MCSP4 | McSPI4 module |
| PER_TA_HSMMC1 | Multimedia card (MMC) controller 1 module |
| PER_TA_HSMMC2 | MMC controller 2 module |
| PER_TA_HSMMC3 | MMC controller 3 module |
| PER_TA_HSMMC4 | MMC controller 4 module |
| PER_TA_HSMMC5 | MMC controller 5 module |
| PER_TA_HDQ | Single-wire serial link low-rate module |

Four ports communicate between the L3 interconnect and the L4_PER interconnect to allow the L3 initiators to access the L4_PER targets. [Table 13-7](#) lists the L4_PER initiator TAs.

For the list of initiators authorized to access the L4 peripheral peripherals, see [Section 13.2.3.2.2, Connectivity Matrix](#).

Table 13-7. L4_PER IAs

| Module Initiator Name | Description |
|-----------------------|------------------------------------|
| PER_IA_0 | L3 sDMA RD interconnect port |
| PER_IA_1 | L3 sDMA WR interconnect port |
| PER_IA_2 | L3 MPU subsystem interconnect port |
| PER_IA_3 | L3 others interconnect port |

13.1.3.2.2 L4_CFG Interconnect Agents

The L4_CFG interconnect handles only transfers to peripherals in the CORE power domain. [Table 13-8](#) lists the TAs.

Table 13-8. L4_CFG TAs

| Module Target Name | Description |
|-----------------------------|----------------------------------------------|
| CFG_TA_SYSCTRL_GENERAL_CORE | System control general core module |
| CFG_TA_SYSCTRL_PADCONF_CORE | System control padconf core module |
| CFG_TA_CM1 | Clock manager 1 module |
| CFG_TA_CM2 | Clock manager 1 module |
| CFG_TA_SDMA | sDMA module |
| CFG_TA_HSI | HS synchronous serial interface (SSI) module |
| CFG_TA_SAR_ROM | Save-and-restore ROM |
| CFG_TA_HSUSBOTG | HS universal serial bus (USB) OTG module |
| CFG_TA_FSUSBHOST | FS USB OTG module |
| CFG_TA_HSUSBHOST | HS USB host module |
| CFG_TA_HSUSBPHY | HS USB PHY module |
| CFG_TA_HSUSBTLL | USB TTL module |
| CFG_TA_DSP | Digital signal processor (DSP) subsystem |
| CFG_TA_SR1 | SmartReflex1 module |
| CFG_TA_SR2 | SmartReflex2 module |

Table 13-8. L4_CFG TAs (continued)

| Module Target Name | Description |
|--------------------|---------------------------------------------------------------|
| CFG_TA_SR3 | SmartReflex3 module |
| CFG_TA_MAILBOX | Mailbox module |
| CFG_TA_SPINLOCK | Spinlock module |
| CFG_TA_FACEDETECT | Face detect module |
| CFG_TA_EMIFFW | EMIF firewall |
| CFG_TA_GPMCFW | GPMC firewall |
| CFG_TA_OCMRAMFW | RAM firewall |
| CFG_TA_SGXFW | SGX firewall |
| CFG_TA_ISSF | ISS firewall |
| CFG_TA_CORTEXM3FW | Cortex-M3 firewall |
| CFG_TA_DSSFW | Display subsystem (DSS) firewall |
| CFG_TA_SL2FW | SL2 firewall |
| CFG_TA_IVAHDFW | Image and video accelerator high-definition (IVA-HD) firewall |
| CFG_TA_EMUSSF | EMU subsystem firewall |
| CFG_TA_ABEFW | Audio back-end (ABE) firewall |
| CFG_TA_L4WKUP | L4_WKUP connection |

A unique port, CFG_IA_0, communicates between the L3 interconnect and the L4_CFG interconnect to allow the L3 initiators to access the L4_CFG targets (see [Table 13-9](#)).

For the list of initiators authorized to access the L4_CFG peripherals, see [Section 13.2.3.2.2, Connectivity Matrix](#).

Table 13-9. L4_CFG IAs

| Module Initiator Name | Description |
|-----------------------|----------------------|
| CFG_IA_0 | L3 interconnect port |

13.1.3.2.3 L4_WKUP Interconnect Agents

The L4_WKUP interconnect handles transfers only to peripherals in the WKUP power domain. [Table 13-10](#) lists the TAs. [Table 13-11](#) lists the L4_WKUP IAs.

Table 13-10. L4_WKUP TAs

| Module Target Name | Description |
|------------------------------|------------------------------------------|
| WKUP_TA_GPIO1 | GPIO1 module |
| WKUP_TA_32KTIMER | 32-kHz timer module |
| WKUP_TA_SAR_RAM | Save-and-restore RAM |
| WKUP_TA_KEYBOARD | Keyboard module |
| WKUP_TA_SYSCTRL_GENERAL_WKUP | System control general WKUP module |
| WKUP_TA_SYSCTRL_PADCONF_WKUP | System control padconf WKUP module |
| WKUP_TA_PRRM | Power reset management module |
| WKUP_TA_SCRM | System clock and reset management module |
| WKUP_TA_WDTIMER2 | WDTIMER2 module |
| WKUP_TA_GPTIMER1 | GPTIMER1 module |

Table 13-11. L4_WKUP IAs

| Module Initiator Name | Description |
|-----------------------|--------------------------|
| WKUP_IA_0 | L4_CFG interconnect port |

13.1.4 Connectivity Matrix

Figure 13-2 shows the functional paths between the L3 interconnect initiator modules and the L3 and L4 TAs. The functional paths are indicated by the use of the following:

- A cell contains a + sign when a functional path exists.
- A cell is blank when a functional path does not exist.

Figure 13-2. L3 Connectivity Matrix

| Master NIU (MN) | Slave NIU (SN) | | | | | | | | | | | | | | | | | |

I3-001

13.2 L3 Interconnect

This section describes the L3 interconnect and its components. With the exception of register points, each component includes functions for the request and response networks.

13.2.1 L3 Interconnect Overview

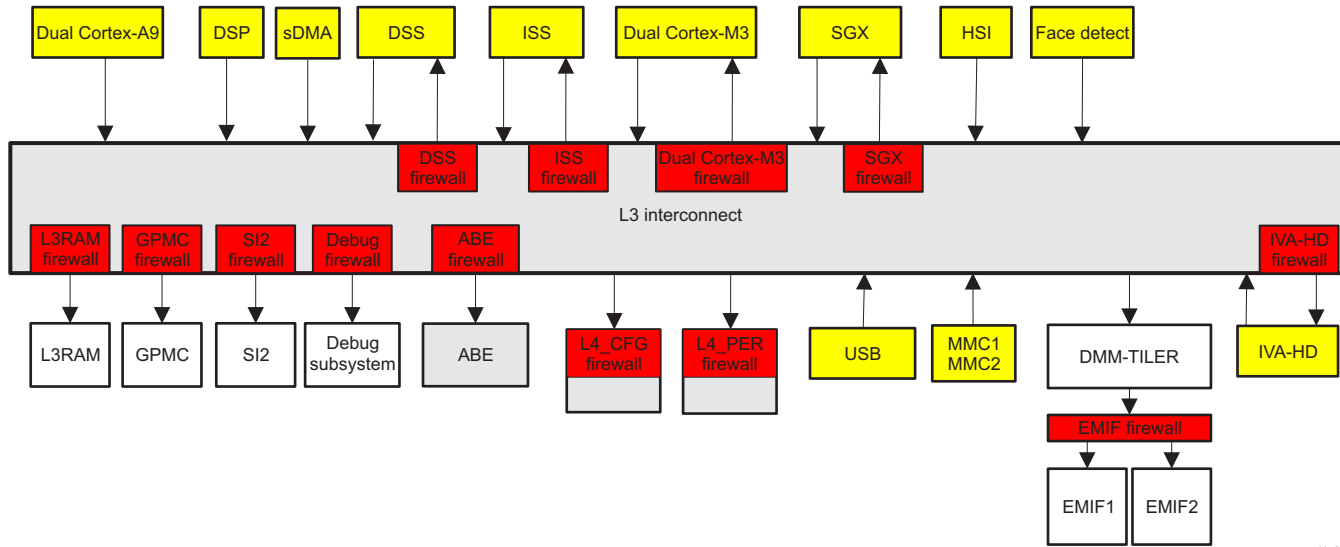

The L3 interconnect links cores in a flexible topology that couples low power with high performance. Innovative physical structures and advanced protocols ensure bandwidth and latency to individual IP cores, providing dedicated connections between IP cores and logical connections over a shared interconnect.

The main features of the L3 interconnects are:

- NIUs: Master NIUs for the IAs and slave NIUs for the TAs
- A partially depleted crossbar exchange network
- A special internal slave NIU for accessing L3 interconnect configuration registers
- True little-endian platform
- Transaction errors tracking and logging registers
- All signaling support for chip-level power-management infrastructure

[Figure 13-3](#) is an overview of the L3 interconnect and the peripherals attached to it.

Figure 13-3. L3 Interconnect Overview

|--------------------|--------------------|-------------------------|----------------|----------------------------|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| L3 | L3_DBG_IRQ | MA_IRQ_9 | Cortex-A9 INTC | Interrupt to the Cortex-A9 |
| | L3_APP_IRQ | D_IRQ_84 | DSP INTC | Interrupt to the DSP |
| | L3_APP_IRQ | MA_IRQ_10 | Cortex-A9 INTC | Interrupt to the Cortex-A9 |

13.2.3 L3 Interconnect Functional Description

13.2.3.1 Module Use in L3 Interconnect

The L3 interconnect network components have ConnID values for each master NIU or slave NIU. The ID uniquely identifies the master NIU or the slave NIU for an interconnect transfer. The interconnect uses ConnIDs for a number of purposes, including the following:

- Slave NIUs for error logging
- Power disconnect slave NIU for error logging
- FLAGMUX to mask interrupts: Three, one for each clock domain
- STATCOLL for configuring and monitoring: The STATCOLL components compute the traffic statistics within a user-defined window and periodically report to the user through the debug interface.
- Bandwidth regulator for configuration: The bandwidth critical masters are IVAHD, ISS, DSS, and SGX.
- Some rate adapters for configuration of throughput ratio

13.2.3.2 Module Distribution

Master NIUs and slave NIUs provide the interface to connect the different modules to their associated interconnect.

[Table 13-15](#) and [Table 13-16](#) list all the modules and subsystems with their associated agents. The agents are listed for each L3 interconnect domain.

13.2.3.2.1 L3 Interconnect Agents

Any initiator or target core is connected to the L3 interconnect through an NIU. NIUs act as entry points to the L3 interconnect, and also include various programming registers. [Table 13-15](#) lists the supported master NIU ports.

Table 13-15. Master NIUs

| Master NIU | Description |
|------------------|---------------------------------------------------|
| L3_MN_CORTEXA9 | Cortex-A9 MPU subsystem |
| L3_MN_DSP | DSP subsystem |
| L3_MN_DSS | Display subsystem |
| L3_MN_MMC1/2 | Multimedia controller |
| L3_MN_IVAHD | Video accelerator subsystem |
| L3_MN_SGX | Graphic accelerator |
| L3_MN_ISS | Imaging accelerator subsystem |
| L3_MN_CORTEXM3 | Cortex-M3 MPU subsystem |
| L3_MN_FACEDETECT | Face detection module |
| L3_MN_SDMA_rd | sDMA |
| L3_MN_SDMA_wr | sDMA |
| L3_MN_HSI | HS synchronous serial interrupt controller (INTC) |
| L3_MN_FSUSB | Full-speed USB host controller |
| L3_MN_HSUSBOTG | HS OTG USB controller |
| L3_MN_HSUSBHOST | Multiport USB host controller |
| L3_MN_DAP | JTAG/emulation access to system resources |

[Table 13-16](#) lists the supported slave NIU ports.

Table 13-16. Slave NIUs

| Slave NIU | Description |
|---------------------|-------------------------------------------|
| L3_SN_OCM_RAM | On-chip memory controller |
| L3_SN_GPMC | GPMC |
| L3_SN_DMM1 | Dynamic memory management |
| L3_SN_DMM2 | Dynamic memory management |
| L3_SN_SGX | Graphic accelerator |
| L3_SN_ISS | Imaging accelerator subsystem |
| L3_SN_IVAHD_CFG | Video accelerator subsystem configuration |
| L3_SN_IVAHD_SL2 | Video accelerator subsystem shared memory |
| L3_SN_DSP | DSP subsystem |
| L3_SN_CORTEXM3 | Cortex-M3 MPU subsystem |
| L3_SN_DSS | Display subsystem |
| L3 interconnect | L3 internal registers |
| L3_SN_ABE | Audio back end |
| L3_SN_L4_CFG | L4 interconnect configuration |
| L3_SN_L4_PER0/1/2/3 | L4 interconnect peripherals |
| L3_SN_L4_EMU | L4 interconnect EMU subsystem |

13.2.3.2.2 L3 Connectivity Matrix

The L3 interconnect is divided into three subclock domains:

- L3_CLK1: Low-power domain
- L3_CLK2: Peripherals and multimedia
- L3_CLK3: Instrumentation (debug)

Each is implemented in a different clock domain.

13.2.3.2.2.1 Clock Domain Mapping of the L3 Interconnect Modules

Each clock domain (CLK1, CLK2, and CLK3) has its own host, flag mux, slave NIUs, and bandwidth regulators.

Table 13-17. L3 Clock Domains and Elements

| Domain | Elements |
|--------|-----------|
| CLK1 | HOST_CLK1 |
| | DMM1/2 |
| | ABE |
| | L4_CFG |
| | FLAGMUX |
| | DSS_BW |

I3-001

13.2.3.2.3 Master NIU Identification

An master NIU ID (ConnID) is assigned to every module in the device. The ID uniquely identifies the master NIU for an interconnect transfer (see Table 13-18). The interconnect uses ConnID values for a number of purposes, including:

- Master source identification for the protection mechanism
- Response route generation
- Firewall error logging
- L3 interconnect error logging

Table 13-18. ConnID Values

| ConnID | Master NIU |
|---------------|-------------------|
| 0x0 | Cortex-A9 |
| 0x4 | DAP |
| 0x8 | DSP |
| 0xC | IVAHD |
| 0x10 | ISS |
| 0x11 | Cortex-M3 |
| 0x12 | FaceDetect |
| 0x14 | sDMA_rd |
| 0x15 | sDMA_wr |
| 0x18 | SGX |
| 0x1C | DSS |
| 0x20 | Reserved |
| 0x22 | Reserved |
| 0x23 | Reserved |
| 0x24 | HSI |
| 0x28 | MMC1 |
| 0x29 | MMC2 |
| 0x2C | Reserved |
| 0x30 | HSUSBHOST |
| 0x31 | HSUSBOTG |
| 0x32 | FSUSB |
| 0x34 | Reserved |

13.2.3.3 Bandwidth Regulators

The bandwidth regulators prevent master NIUs from consuming too much bandwidth of a link, or a slave NIU that is shared between several data flows: packets are then transported at a slower rate. The value of a bandwidth can be programmed in the bandwidth regulator. When the bandwidth is below the programmed value, the pressure bit is set to 1, giving priority to this master. When the bandwidth is above the programmed value, the pressure bit is set to 0 and the concerned master has the same weight as others.

A counter is used to store the sum of data lengths (in bytes) of each packet passing through the bandwidth regulator, and a value equal to the expected bandwidth is subtracted from the counter at each clock cycle. The value of the counter is compared to a programmable threshold (called Watermark), and this comparison determines whether the packet is processed with high pressure for minimum latency or low pressure for best effort processing.

The bandwidth regulator monitors the traffic using open connections between the initiators and the targets. If there is insufficient bandwidth allocated to the connection, the bandwidth regulator can increase the pressure on connections. Generally, the connection is a dataflow between master and slave NIUs. In some cases, the bandwidth regulator is attached to the master and monitors single dataflow to a target (single connection).

Figure 13-5. Bandwidth Regulator Pressure Settings

13-024

When Counter Value (bytes) falls below Watermark, the pressure bit is assigned to 1

The bandwidth regulator effective resolution is set to 12.5 MBps. The maximum average bandwidth (max watermark value) computed in a moving window is set to up to 4096 bytes of payload. These settings are implemented by hardware.

The following is an example of bandwidth regulator settings:

The bandwidth regulator is set to run at 200 MHz and the application (DSS bandwidth consumption of HD panel for 1280x720 in RGB24) requires an expected bandwidth of 165.888 MBps (± 5 MBps), computed through a moving window of 5 μ s (1000 cycles). To attribute high pressure on all DSS packet requests, the watermark could be set to the maximum bandwidth needed in the 5- μ s window.

Considering this example, the settings of the bandwidth regulator are:

- **L3_BW_R_WATERMARK**[11:0] WATERMARK = moving window \times expected bandwidth = 829.44 bytes = 0x33D
- **L3_BW_R_BANDWIDTH**[15:0] BANDWIDTH = 165.888 MBps / effective resolution = 13,271 = 0xD

The bandwidth registers regulate the packet flow by applying flow control on the RX port, thus ensuring that the traffic does not exceed the allocated bandwidth. The next packet is sent only when an internal timer expires. The registers in this group are:

- **L3_BW_R_WATERMARK**: Gives the amount of data allowed to exceed the average bandwidth during a short time period
- **L3_BW_R_PRESS**: Describes the pressure applied to outgoing packets
- **L3_BW_R_CLEARHISTORY**: Resets the traffic counter when set to 1. It is used after an update in the **L3_BW_R_BANDWIDTH** and **L3_BW_R_WATERMARK** registers (see [Section 13.2.5.1.6, L3 BW Regulator Register Summary and Description](#)).

13.2.3.4 Flag Mux Generators

The flag mux generator collects information such as errors and interrupts from slave NIUs and the interconnect firewall. The result signals are then sent to the MPU INTC without interfering with the interconnect traffic. The L3_FLAGMUX_MASK registers can be used to prevent the flag mux from seeing certain events.

The unit has a standard COREREG register for identification of the attached core type. The [L3_FLAGMUX_STDHOSTHDR_VERSIONREG](#) register identifies the characteristics of the attached core. The unit-specific registers (MASK bit 0 or bit 1 of the flag inputs, and L3_FLAGMUX_REGERR bit 0 or bit 1) are used to read the input errors. Each register is dedicated to reporting the bit corresponding to the register number; for example, [L3_FLAGMUX_REGERR0](#) reports on bit 0, and [L3_FLAGMUX_REGERR1](#) reports on bit 1. Any given L3_FLAGMUX_REGERR register reports the same bit for all flag source inputs (see [Table 13-162](#)).

13.2.3.5 Rate Adapter Generators

The rate adapter generators give the option to configure the L3 interconnect to work in auto-adaptive mode or pipeline mode for sending the packets by using the CNF register. The rate adapter can be configured in store-and-forward mode when the throughput ratio is not well defined, or in auto-adaptive mode when the throughput ratio is predictable. Because the ratios are predictable in the L3 interconnect, the rate adapters are always used in auto-adaptive mode, except for the rate adapter on the L4_CFG and L4_ABE responses path. L4_CFG and L4_ABE are configured in store-and-forward mode. The main rate adapt registers are:

- CLK1_RATE_ADAPT_RESP_32TO128_CLK1: Removes WAIT cycles on responses coming from ABE, L4CFG, and power disconnect to host
- CLK2_RATE_ADAPT_RESP_32TO128_CLK2: Removes WAIT cycles on responses coming from CLK2 32-bit slaves (see [Table 13-192](#))

13.2.3.6 Statistic Collectors Group

Statistic collectors are internal masters that share the same master address as the master NIUs. These components compute the traffic statistics within a defined window and periodically report through the DEBUG interface. The key features of the statistic collector are:

- Nonintrusive monitoring
- Programmable filters and counters
- Collects results at a programmable time interval

Event detectors are programmed through the [L3_STCOL_REQEVT](#) and [L3_STCOL_RSPEVT](#) configuration registers for request and response ports, respectively. The following events can be identified:

- Word transfer
- WAIT cycles
- Flow control
- Payload transfers
- Latency measurements

Performance monitoring is enabled through the [L3_STCOL_EN](#) register. The [L3_STCOL_SOFTEN](#) register enables software to monitor the performance. Event muxes are programmed through the [L3_STCOL_EVTMUX_SELO](#) configuration register, which determines which port will be monitored by a filter configured by the filter registers (see).

Filters are programmed through the configuration register, along with additional selection criteria programmed through the mask/match registers (see [Table 13-201](#)). A filter can be configured to accept or reject:

- Read operations
- Write operations
- Errors
- Addresses

Filter operation is programmed through the L3_STCOL_OP registers (see [Table 13-201](#)).

13.2.3.7 L3 Protection and Firewalls

Device protection relies on L3 firewalls and their configuration.

13.2.3.7.1 L3 Firewall Reset

The values of L3 firewall registers on reset are tied in hardware or exported from the control module registers.

Values exported from the control module are intended to give defined rights to the firewalls at reset and thus ensure the content after going out of reset. Because the control module consists of retention flip-flops (RFFs), which immunize it against register content loss during retention power state, the registers of the control module storing the exported values are not subject to a soft reset.

The L3 firewall registers are also retention-capable and are immune against content loss during CORE RETENTION power state. The control module registers are reset by a cold reset only, whereas the L3 firewall registers are reset by clearing the [REGUPDATE_CONTROL\[1\] FW_LOAD_REQ](#) bit. When the [REGUPDATE_CONTROL\[1\] FW_LOAD_REQ](#) bit comes back automatically to 1, the exported values are loaded.

CAUTION

Before reprogramming the firewall registers and/or before using the [FW_LOAD_REQ](#) mechanism, the request must be asserted by configuring the [REGUPDATE_CONTROL\[0\] BUSY_REQ](#) bit.

To load the exported values at run time:

1. Set the [REGUPDATE_CONTROL\[0\] BUSY_REQ](#) bit to 0x1 to ensure that no transaction can reach the slave NIU (suspend).
2. Clear the [REGUPDATE_CONTROL\[1\] FW_LOAD_REQ](#) bit by writing 0x1 to it.
3. Wait until the [REGUPDATE_CONTROL\[1\] FW_LOAD_REQ](#) bit is reset to 0x1 by hardware.
4. Set the [REGUPDATE_CONTROL\[0\] BUSY_REQ](#) bit to 0x0 to allow transactions to reach the slave NIU (resume).

To reprogram the firewall registers at run time:

1. Set the [REGUPDATE_CONTROL\[0\] BUSY_REQ](#) bit to 0x1 to ensure that no transaction can reach the slave NIU (suspend).
2. Upload the new values to all firewall registers.
3. Set the [REGUPDATE_CONTROL\[0\] BUSY_REQ](#) bit to 0x0 to allow transactions to reach the slave NIU (resume).

NOTE: Hardware reset values can be modified by exported values from the control module at reset.

13.2.3.7.1.1 L3 Firewall – Exported Reset Values

[Table 13-19](#) and [Table 13-20](#) list the exported reset values and mapping, respectively.

Table 13-19. L3 Firewall Exported Reset Values

| MRM_PERMISSION_REGION_LOW_j [15:12] | MRM_PERMISSION_REGION_LOW_j [11:0] |
|--------------------------------------------------------|-------------------------------------------------------|
| 0x0 | 0xFFF |
| 0xF | 0xFFF |
| 0x0 | 0x038 |
| 0x2 | 0x038 |

Table 13-20. L3 Firewall Exported Values Mapping

| CONTROL_CORE_L3_HW_FW_EXPORTED_VALUES_CONF Bits | Slave NIU Firewall |
|-----------------------------------------------------------------|--------------------|
| [0] and [16] | GPMC |

Table 13-20. L3 Firewall Exported Values Mapping (continued)

| CONTROL_CORE_L3_HW_FW_EXPORTED_VALUES_CONF Bits | Slave NIU Firewall |
|--------------------------------------------------------|----------------------------------|
| [3] and [19] | L3 RAM |
| [4] and [20] | DSS |
| [5] and [21] | ISS and dual Cortex-M3 subsystem |
| [6] and [22] | SGX |
| [7] and [23] | SL2 |
| [8] and [24] | IVA-HD |
| [11] and [27] | EMIF |
| [12] and [28] | DEBUG |
| [13] and [29] | L4 AUDIO |

For more information, see [Chapter 18, Control Module](#).

13.2.3.7.2 Power Management

As part of the system-wide power-management scheme, the L3 interconnect goes into IDLE state after receiving a request from the power, reset, and clock management (PRCM) module after all commands are serviced. This function is handled by hardware.

To reduce power consumption, the L3 interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

Retention is performed on all software-accessible registers:

- Statistic collectors
- Internal rate adapters
- Bandwidth regulators
- TAs
- Firewalls

This process prevents reconfiguration after a clock domain switches off.

13.2.3.7.3 L3 Firewall Functionality

The access to the slave NIUs is granted only to master NIUs according to in-band attributes sent in each transaction crossing the L3 interconnect, such as:

- MCMD: Specifies the type of access (read or write) required by the master NIU
- ConnID: Used to determine the permission of the master NIU
- MReqInfo: Transaction attribute adding information about the access type

[Table 13-21](#) lists the MReqInfo Values.

Table 13-21. MReqInfo Values

| Qualifier | Access Definition | Access Description |
|------------------|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MReqType | 0: Data 1: Opcode | Indicates whether the request is for instruction fetch or data access |
| MReqDebug | 0: Functional 1: Debug | When set, indicates that the request has been issued by a master NIU in DEBUG state |
| MReqSupervisor | 0: User 1: Privilege | When set, indicates that the request is qualified with the supervisor attribute. It can be provided by a processor running in supervisor mode or by a module that inherited this attribute from the processor (DMA channel with a supervisor attribute). |

The firewall comparison mechanism enables access to a protected slave NIU only when a correct combination of three MReqInfo in-band parameters is transmitted.

MReqInfo is a combination of a fixed 3-bit pattern that corresponds to a combination of the parameters MReqDebug, MReqType, and MReqSupervisor. See [Table 13-22](#).

Table 13-22. L3 ReqInfo Mapping

| | ReqInfo Name | MReqDebug | MReqType | MReqSupervisor |
|--------------|---------------------|-----------|----------|----------------|
| Master NIUs | L3_MN_CORTEXA9 | x | x | x |

13.2.3.7.3.1 Protection Regions

Each slave NIU address space is subdivided into protection regions (maximum of 10). The regions are configurable with a size of 4-KB granularity. The firewalls can also be multiport while using the description of the same regions for dual access memories or to support interleaving mechanisms on several memories.

[Table 13-23](#) lists the number of protected regions and ports for each slave NIU.

Table 13-23. Slave NIU Firewall and Region Configuration

| Slave NIU | Firewall | Number of Regions | Number of Ports |
|-----------|----------|-------------------|-----------------|
| L3 RAM | L3 RAM | 10 | 1 |
| GPMC | PMC | 8 | 1 |

Table 13-23. Slave NIU Firewall and Region Configuration (continued)

| Slave NIU | Firewall | Number of Regions | Number of Ports |
|--------------------------|----------------|-------------------|-----------------|
| SL2 | SL2 | 1 | 1 |
| SGX | SGX | 1 | 1 |
| ISS | ISS | 1 | 1 |
| Dual Cortex-M3 subsystem | Dual Cortex-M3 | 1 | 1 |
| DSS | DSS | 1 | 1 |
| IVA-HD | IVA-HD | 1 | 1 |
| DEBUG subsystem | DEBUG | 2 | 1 |
| ABE | ABE | 1 | 1 |
| EMIF | EMIF | 8 | 3 |

Two types of regions are distinguished in a slave NIU firewall:

- Default region: Available in all slave NIUs. It covers the entire slave NIU address range and must be reset or overlaid by other firewall configured regions, because it always has the lowest priority.
- Normal region: The number of normal regions varies in a slave NIU; they have identical capabilities (see [Table 13-23](#)).

Each region has the following characteristics:

- Start address: Physical slave NIU start address
- End address: Physical slave NIU end address
- Specific access rights (see [Section 13.2.3.7.3.3](#), *Protection Mechanism per Region Examples*)
- Priority level from 0 (lowest) to 10 (highest)

Depending on its priority level, a region can override the settings of another region; the access rights of the region with the highest priority apply. All regions have a fixed (not configurable) priority level that corresponds to their number: Region 1 has priority level 1, region 2 has priority level 2, and so on.

[Figure 13-6](#) shows the priority level with associated regions. This priority level scheme allows multiplying the flexibility and capability of the firewall. [Figure 13-6](#) shows a 7-region firewall setting that creates 13 regions (twice the number of regions created than originally available).

Figure 13-6. L3 Interconnect Region Overlay and Priority Level Overview

13-003

The address range covered by the regions is defined in the [START_REGION_i](#) and [END_REGION_i](#) registers. The boundary checks are done on a minimum size of 4-KB pages; thus, bits [11:0] of those 32-bit registers are not checked.

The address space size of the slave NIUs ([bits [31:12]]) depends on the size of the slave NIU to protect (that is, if a memory is only 48KB, then the size is defined through bits [16:12] of the slave NIU start/end address registers of the firewall region ([START_REGION_i\[16:12\]](#) and [END_REGION_i\[16:12\]](#)).

NOTE: The EMIF firewall sees only the 4GB that require protection.

Bit [31] is replaced by bit [32] of the EMIF address space seen by firewalls to have 2GB of LPDDR2-SDRAM and 2GB of LPDDR2-NVM contiguous.

For more information, see [Section 15.3](#), *EMIF Controller*.

On multiport firewalls (EMIF), the checking of each REGION {0, n} can be activated on one or several ports at the same time. However, if interleaving is not desired on some parts of the protected memory space, it is possible to apply or not apply region checking on selected ports using the region enable/disable on port instance capability of the [END_REGION_i](#) register.

Most slave NIUs support only one input port (port 0) except:

- The EMIF module protected by the EMIF firewall has three ports:
 - Port 0 for Cortex-A9 accesses
 - Port 1 for the first L3 interconnect accesses

- Port 2 for the second L3 interconnect accesses

A region can be applied or not to each port independently. To enable and disable the regions:

- For port 0: Set/clear the [END_REGION_i\[0\]](#) REGION_ENABLE_PORT0 bit (for all L3 firewalls).
- For port 1: Set/clear the [END_REGION_i\[1\]](#) REGION_ENABLE_PORT1 bit (only for EMIF firewalls).
- For port 2: Set/clear the [END_REGION_i\[2\]](#) REGION_ENABLE_PORT2 bit (only for EMIF firewalls).

13.2.3.7.3.2 L3 Firewall Registers Overview

[Table 13-24](#) and [Table 13-25](#) list the L3 firewall permission-setting registers.

Table 13-24. L3 Firewall Read/Write Permission-Setting Register

| Register Name | Bits | Field Name | Description (see Table 13-18) | Field Modifiability |
|----------------------------------------------|------|------------|------------------------------------------------|---------------------|
| MRM_PERMISSION_REGION_HIGH_j | 31 | RESERVED | Reserved | – |
| | 30 | RESERVED | Reserved | – |
| | 29 | RESERVED | Reserved | – |
| | 28 | RESERVED | Reserved | – |
| | 27 | RESERVED | Reserved | – |
| | 26 | RESERVED | Reserved | – |
| | 25 | W12 | ConnID = 12 write permission | RW |
| | 24 | R12 | ConnID = 12 read permission | RW |
| | 23 | RESERVED | Reserved | – |
| | 22 | RESERVED | Reserved | – |
| | 21 | W10 | ConnID = 10 write permission | RW |
| | 20 | R10 | ConnID = 10 read permission | RW |
| | 19 | W9 | ConnID = 9 write permission | RW |
| | 18 | R9 | ConnID = 9 read permission | RW |
| | 17 | W8 | ConnID = 8 write permission | RW |
| | 16 | R8 | ConnID = 8 read permission | RW |
| | 15 | W7 | ConnID = 7 write permission | RW |
| | 14 | R7 | ConnID = 7 read permission | RW |
| | 13 | W6 | ConnID = 6 write permission | RW |
| | 12 | R6 | ConnID = 6 read permission | RW |
| | 11 | W5 | ConnID = 5 write permission | RW |
| | 10 | R5 | ConnID = 5 read permission | RW |
| | 9 | W4 | ConnID = 4 write permission | RW |
| | 8 | R4 | ConnID = 4 read permission | RW |
| | 7 | W3 | ConnID = 3 write permission | RW |
| | 6 | R3 | ConnID = 3 read permission | RW |
| | 5 | W2 | ConnID = 2 write permission | RW |
| | 4 | R2 | ConnID = 2 read permission | RW |
| | 3 | W1 | ConnID = 1 write permission | RW |
| | 2 | R1 | ConnID = 1 read permission | RW |
| | 1 | W0 | ConnID = 0 write permission | RW |
| | 0 | R0 | ConnID = 0 read permission | RW |

Table 13-25. L3 Firewall Permission-Setting Register

| Register name | Type of Permission | Bits | Field Name | Description | Field Modifiability |
|-----------------------------|--------------------|-------------------------|---------------|---------------------------|---------------------|
| MRM_PERMISSION_REGION_LOW_j | DEBUG | 15 | PUB_PRV_DEBUG | Privilege debug allowed | RW |
| | | 14 | PUB_USR_DEBUG | User debug allowed | RW |
| | Access | 13:12 | Reserved | Reserved | RW |
| | | 11 | PUB_PRV_WRITE | Privilege write allowed | RW |
| | | 10 | PUB_PRV_READ | Privilege read allowed | RW |
| | | 9 | PUB_PRV_EXE | Privilege exe allowed | RW |
| | | 8 | PUB_USR_WRITE | User write access allowed | RW |
| | | 7 | PUB_USR_READ | User read access allowed | RW |
| 6 | PUB_USR_EXE | User exe access allowed | RW | | |

13.2.3.7.3.3 Protection Mechanism per Region Examples

The access permission of each region is configurable and defined through the [MRM_PERMISSION_REGION_HIGH_j](#) and [MRM_PERMISSION_REGION_LOW_j](#) registers (see [Section 13.2.3.7.3.2, L3 Firewall Registers Overview](#)).

Master NIU permissions:

- To give read access to the master NIU with ConnID = n, set the [MRM_PERMISSION_REGION_HIGH_j\[n * 2\]](#) Rn bit.
- To give write access to the master NIU with ConnID = n, set the [MRM_PERMISSION_REGION_HIGH_j\[n * 2 + 1\]](#) Wn bit.

Debug permissions:

- To give privilege debug access, set the [MRM_PERMISSION_REGION_LOW_j\[15\]](#) PUB_PRV_DEBUG bit.
- To give user debug access, set the [MRM_PERMISSION_REGION_LOW_j\[14\]](#) PUB_USR_DEBUG bit.

User, read/write/executable permissions:

- To give privilege write access, set the [MRM_PERMISSION_REGION_LOW_j\[11\]](#) PUB_PRV_WRITE bit.
- To give privilege read access, set the [MRM_PERMISSION_REGION_LOW_j\[10\]](#) PUB_PRV_READ bit.
- To give privilege exe access, set the [MRM_PERMISSION_REGION_LOW_j\[9\]](#) PUB_PRV_EXE bit.
- To give user write access, set the [MRM_PERMISSION_REGION_LOW_j\[8\]](#) PUB_USR_WRITE bit.
- To give user read access, set the [MRM_PERMISSION_REGION_LOW_j\[7\]](#) PUB_USR_READ bit.
- To give user exe access, set the [MRM_PERMISSION_REGION_LOW_j\[6\]](#) PUB_USR_EXE bit.

Example: To provide debug write privilege access to the master NIU ConnID = 7, the following bits must be set:

- [MRM_PERMISSION_REGION_HIGH_j\[15\]](#) W7
- [MRM_PERMISSION_REGION_LOW_j\[15\]](#) PUB_PRV_DEBUG

13.2.3.7.3.4 L3 Firewall Error Logging

If a protection violation error is detected, the following signals are generated:

- An in-band error is generated to the master NIU of the access.
- An interrupt is generated to the Cortex-A9 and DSP INTCs.

The L3 interconnect does not differentiate errors generated by firewalls from all other supported types of errors.

An in-band error is generated by modules each time an access is not allowed. When an in-band error is sent back into the transaction it is seen as an external prefetch or data abort by the initiator, depending on whether the transaction was an instruction fetch or a data access.

Information about in-band errors is logged into two registers:

- [ERROR_LOG_k](#): Logs the information about the start/end address of the hit region and the qualifiers of the transaction
- [LOGICAL_ADDR_ERRLOG_k\[31:12\]](#): Logs the address of the failed access

NOTE: When a multiport firewall is implemented, these registers are duplicated for each port.

Table 13-26 lists the L3 firewall error-logging registers.

Table 13-26. L3 Firewall Error-Logging Registers

| Register Name | Register Field Name | Field Modifiability | Parameter Comments |
|-----------------------------|----------------------------|---------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ERROR_LOG_k | RESERVED[31:24] | Read only | Reads return 0s. |
| | BLK_BURST_VIOLATION[23] | Read/write | Read 0x1: 2D burst not allowed or exceeds allowed size. Write to clear the ERROR_LOG_k and LOGICAL_ADDR_ERRLOG_k registers. |
| | RESERVED[22] | Read only | Reads return 0s. |
| | REGION_START_ERRLOG[21:17] | Read/write | Read: Wrong access hit this region number. Write to clear the ERROR_LOG_k and LOGICAL_ADDR_ERRLOG_k registers. |
| | REGION_END_ERRLOG[16:12] | Read/write | Read: Wrong access hit this region number. Write to clear the ERROR_LOG_k and LOGICAL_ADDR_ERRLOG_k registers. |
| | REQINFO_ERRLOG[11:0] | Read/write | Mapping of the error according to the reqinfo vector: [11:8] ConnID [3:0] [7] MCMD [0] [3] MReqDebug [1] MReqSupervisor [0] MReqType |

L3 firewall errors can be cleared by writing to the [ERROR_LOG_k](#) register in the firewall that recorded the error. Clearing the [ERROR_LOG_k](#) register deasserts the corresponding error if it exists.

The L3 firewall register [ERROR_LOG_k](#) must be cleared before clearing the [CONTROL_CORE_SEC_ERR_STATUS_FUNC](#) and [CONTROL_CORE_SEC_ERR_STATUS_DEBUG](#) registers in the control module.

When a protection violation occurs, an interrupt is sent to the MPU and IVAHD INTC (if enabled). An in-band error is sent back, and an error is logged in the [CONTROL_SEC_ERR_STATUS_FUNC](#) and [CONTROL_SEC_ERR_STATUS_DEBUG](#) registers, depending on the functional mode:

- In application mode:
 - [CONTROL_SEC_ERR_STATUS_FUNC\[01\]](#) – L3 RAM protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[02\]](#) – GPMC protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[03\]](#) – EMIF protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[04\]](#) – IVAHD protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[05\]](#) – Cortex-M3 protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[06\]](#) – SL2 protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[13\]](#) – SGX protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[14\]](#) – DSS protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[15\]](#) – ISS protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[18\]](#) – DEBUG protection violation
 - [CONTROL_SEC_ERR_STATUS_FUNC\[19\]](#) – ABE protection violation
- In debug mode:
 - [CONTROL_SEC_ERR_STATUS_DEBUG\[01\]](#) – L3 RAM protection violation

- CONTROL_SEC_ERR_STATUS_DEBUG[02] – GPMC protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[03] – EMIF protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[04] – IVAHD protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[05] – Cortex-M3 protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[06] – SL2 protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[13] – SGX protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[14] – DSS protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[15] – ISS protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[18] – DEBUG protection violation
- CONTROL_SEC_ERR_STATUS_DEBUG[19] – ABE protection violation

For more information, see [Chapter 18, Control Module](#).

13.2.3.7.3.5 L3 Firewall Default Configuration

[Table 13-27](#) summarizes the configuration of the L3 firewalls.

Table 13-27. L3 Firewalls Default Configurations

| Device/Region: 0 | | | | | | |
|----------------------|-------------|-----------------|------------|--------------|------------------------------------|------------------------------------------------------------------------------------------------|
| Permission Type | Reset Value | Reset Value | Reset Type | Run Time | Firewall Register (where j = 0) | Control Module Register |
| ACCESS_PERMISSION | All | 0xFFFF | Exported | Configurable | MRM_PERMISSION_REGION_LOW_j[11:0] | CONTROL_CORE_L3_HW_FW_EXPORTED_VALUES_CONF[k] |
| DEBUG_PERMISSION | All | 0xF | Exported | Configurable | MRM_PERMISSION_REGION_LOW_j[15:12] | CONTROL_CORE_L3_HW_FW_EXPORTED_VALUES_CONF[l] CONTROL_CORE_L3_HW_FW_EXPORTED_VALUES_CONF[k] |
| INITIATOR_PERMISSION | All | 0xFFFF FFFFF | Tied | Configurable | MRM_PERMISSION_REGION_HIGH_j[31:0] | N/A |

NOTE: For the values of k and l, see [Table 13-28](#).

Table 13-28. Control Module Register – Factorization

| Variable Value | | Module Name | Regions |
|----------------|----|--------------------|----------------|
| k | l | | |
| 3 | 19 | L3 RAM firewall | Regions 1 to 9 |
| 0 | 16 | GPMC firewall | Regions 1 to 7 |
| 7 | 23 | SL2 firewall | Regions 1 to 7 |
| 6 | 22 | SGX firewall | Regions 1 to 7 |
| 5 | 21 | ISS firewall | Regions 1 to 7 |
| 5 | 21 | Cortex-M3 firewall | Regions 1 to 7 |
| 4 | 20 | DSS firewall | Regions 1 to 7 |
| 8 | 24 | IVAHD firewall | Regions 1 to 7 |
| 12 | 28 | DEBUG firewall | Region 1 |
| 13 | 29 | ABE firewall | Region 1 |
| 11 | 27 | EMIF firewall | Regions 1 to 7 |

13.2.3.8 L3 Interconnect Error Handling

Error logging is enabled in the L3 interconnect. The three major types of errors are:

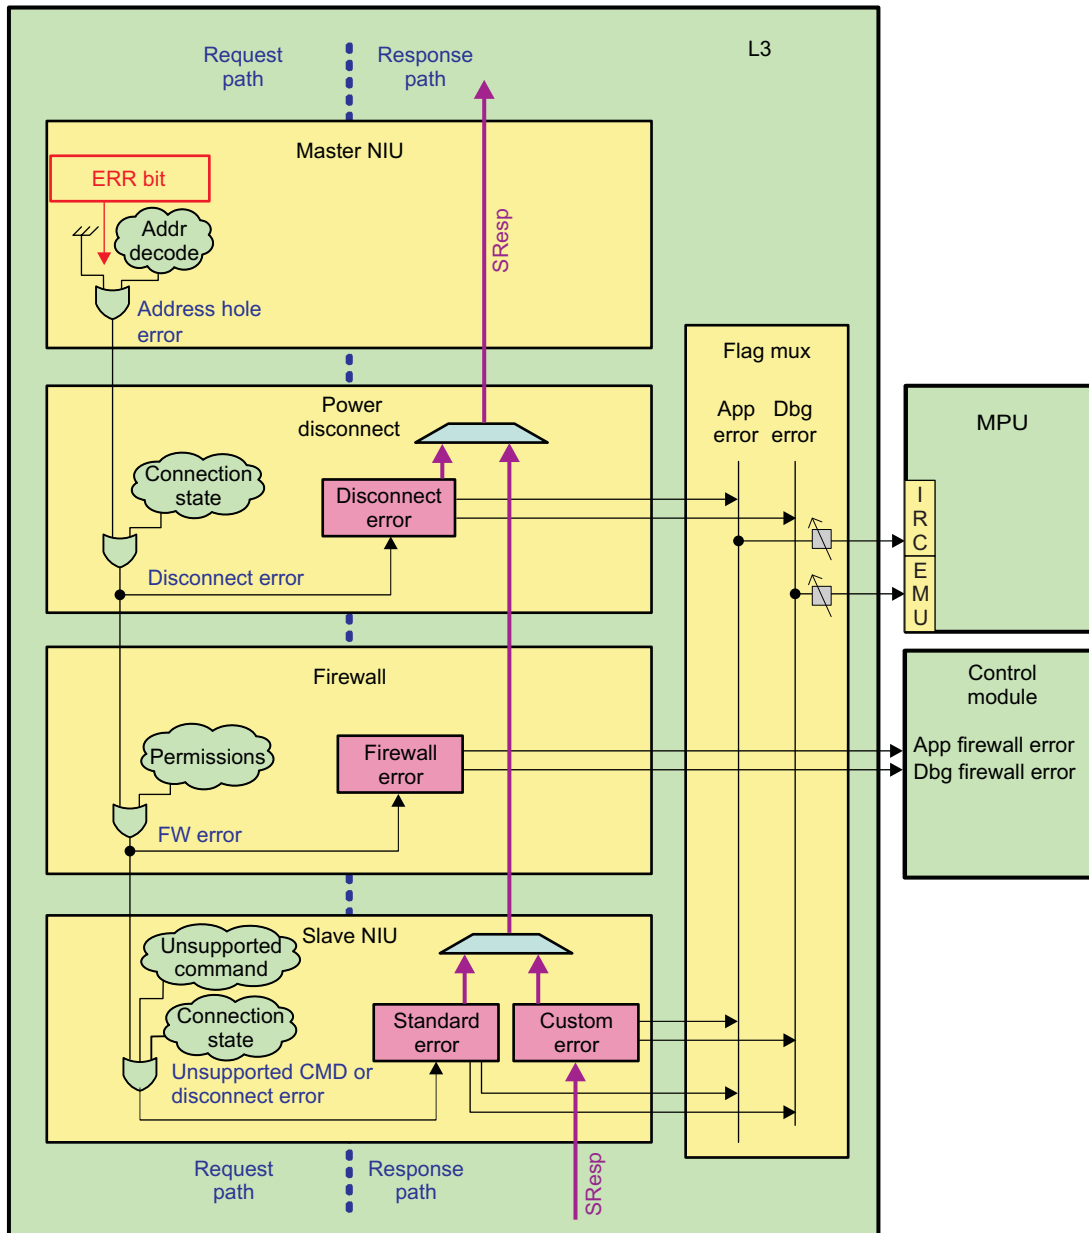

- Slave NIU errors
- Firewall errors (see [Section 13.2.3.7.3.4, L3 Firewall Error Logging](#))

- Flag mux errors

13.2.3.8.1 Global Error-Routing Scheme

Figure 13-7 shows the L3 global error-routing scheme.

Figure 13-7. L3 Global Error-Routing Scheme

13-005

13.2.3.8.2 Slave NIU Error Logging

Error logging is implemented only at slave NIUs. Because the interconnect does not support master NIU error logging, an erroneous packet must be created and sent to one of the slave NIUs. The slave NIU that receives an erroneous packet is predictable but can change per master (see Table 13-29).

Table 13-29. L3 Connectivity and Holes Error Routing

| Master | Connectivity and Holes Errors Logged Into Slave NIUs |
|------------------|------------------------------------------------------|
| L3_MN_DAP | L3_SN_GPMC |
| L3_MN_CORTEXM3 | |
| L3_MN_CORTEXA9 | |
| L3_MN_SDMA_RD | |
| L3_MN_SDMA_WR | |
| L3_MN_DSP | |
| L3_MN_IVANHD | L3_SN_DMM1 |
| L3_MN_MMC1 | |
| L3_MN_MMC2 | |
| L3_MN_SGX | |
| L3_MN_DSS | L3_SN_DMM2 |
| L3_MN_ISS | |
| L3_MN_FACEDETECT | |
| L3_MN_FSUSB | |
| L3_MN_HSUSBOTG | L3_SN_OCM_RAM |
| L3_MN_HSI | L3_SN_ABE |
| L3_MN_HSUSBHOST | |

The slave NIU can be configured to report standard errors (errors generated within the interconnect):

- Firewall error: Protection violation; this error indicates that a request was rejected by a firewall and is reported to the control module. For more information, see [Section 13.2.3.7.3.4, L3 Firewall Error Logging](#).
- Address hole: This error reports an unknown address for a request. The address map is local to each master NIU; therefore, an address hole error is reported each time a master NIU requests an access to a slave NIU to which it is not logically connected, even if this address exists in the global L3 address map. This error is detected only once per burst.
- Unsupported commands: This error reports that the master NIU sent a command that cannot be processed, because the slave NIU cannot accept it and no conversion to another command is possible. This error is detected only once per burst.
- Report custom errors: Basically, when the slave answer is SResp = ERR
- Report severity level, for standard error and custom errors:
 - None: Error logging for this type of error is disabled.
 - Error: Error is logged for this type of error.
 - Fault: Error is logged and interrupt is generated for this type of error.
- Generate interrupt on 2 bits depending on the MReqDebug qualifier:
 - Application error -> Fault[0]
 - Debug error -> Fault[1]

By default, all slave NIUs are configured with standard and custom error levels set to FAULT. The errors are reported on the two flag muxes (see [Figure 13-7](#)), depending on the access type, application or debug. For more information, see [Section 13.2.3.8.3, Flag Mux Error Logging](#).

The slave NIU power-disconnect component also has error logging enabled. This is because the slave NIU in this case is in a clock domain that is switched off and therefore cannot catch the error. By nature, this component can generate only standard errors. By default, it is configured with the error level set to FAULT.

Wake up on demand: If an error packet reaches a slave NIU that is set with MDiscBehave = 1 (wake up on demand), then the active signal is asserted and L3 processes the error generation when the slave is awake. This is inefficient but it simplifies NIU implementation and should not be a problem, because errors are supposed to occur only during software debug.

13.2.3.8.3 Flag Mux Error Logging

All fault signals are sent to a flag mux component. There are four important FLAGMUX registers:

- [L3_FLAGMUX_MASK0](#): Masks application error sources
- [L3_FLAGMUX_MASK1](#): Masks debug error sources
- [L3_FLAGMUX_REGERR0](#): Checks which application error sources are active
- [L3_FLAGMUX_REGERR1](#): Checks which debug error sources are active

The two L3_FLAGMUXMASK registers mask bit 0 or bit 1 of the flag inputs, and the L3_FLAGMUX_REGERR registers read input errors. Each register is dedicated to reporting the bit corresponding to the register number.

[Table 13-30](#) describes the mapping of the flags to the corresponding sources.

Table 13-30. Interconnect Flag Mapping

| | Flag Mux Input | Source |
|---------------|----------------|-----------------|
| CLK1 flag mux | 0 | L3_SN_DMM1 |
| | 1 | L3_SN_DMM2 |
| | 2 | L3_SN_ABE |
| | 3 | L3_SN_L4CFG |
| | 4 | CLK2 PWR DISC |
| CLK2 flag mux | 0 | L3_SN_Cortex-M3 |
| | 1 | L3_SN_DSS |
| | 2 | L3_SN_GPMC |
| | 3 | L3_SN_ISS |
| | 4 | L3_SN_IVAHD |
| | 5 | Reserved |
| | 6 | L3_SN_L4PER0 |
| | 7 | L3_SN_OCMCRAM |
| | 8 | L3_SN_GPMC |
| | 9 | L3_SN_SGX |
| | 10 | L3_SN_SL2 |
| | 11 | Reserved |
| | 12 | CLK1 PWR DISC |
| | 13 | Reserved |
| | 14 | Reserved |
| | 15 | L3_SN_L4PER3 |
| | 16 | L3_SN_L4PER1 |
| 17 | L3_SN_L4PER2 | |
| CLK3 flag mux | 0 | DEBUGSS |

13.2.3.8.4 Severity Level of Standard and Custom Errors

The slave NIU registers are important for error logging.

- The [L3_TARG_STDERRLOG_SVRTSTDLVL](#) register shows the severity level for standard errors. According to the severity level, error logging is disabled, enabled with level ERROR, or enabled with level ERROR and flag FAULT.
- The [L3_TARG_STDERRLOG_SVRTCUSTOMLVL](#) register shows the severity level for custom errors (see).
- The [L3_TARG_STDERRLOG_MAIN](#) register is the main register for error-logging management. It shows the validity of the logged information, standard or custom.
- The [L3_TARG_STDERRLOG_HDR](#) register stores packets in case of a standard error.

- The [L3_TARG_STDERRLOG_MSTADDR](#) register returns the MSTADDR field of the logged packet.
- The [L3_TARG_STDERRLOG_SLVADDR](#) register returns the SLVADDR field of the stored packet.
- The [L3_TARG_STDERRLOG_INFO](#) register saves the information field of the logged packet.

13.2.4 L3 Interconnect Programming Guide

13.2.4.1 L3 Interconnect Low-Level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L3 interconnect module.

13.2.4.1.1 Global Initialization

13.2.4.1.1.1 Global Initialization of Surrounding Modules

This section identifies the requirements for initializing the surrounding modules when the L3 interconnect module is to be used for the first time after a device reset. The initialization of surrounding modules is based on the integration and environment of the L3 interconnect. For more information, see [Section 13.2.2, L3 Interconnect Integration](#).

Table 13-31. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| PRCM | For information about the configuration of the PRCM module, see Chapter 3, Power, Reset, and Clock Management . |
| Control module | For information about the configuration of the control module, see Chapter 18, Control Module . |
| MPU INTC | The MPU INTC must be configured to enable interrupts from the L3 interconnect module. See Chapter 17, Interrupt Controllers . |
| sDMA | For information about the configuration of the sDMA, see Chapter 16, sDMA . |
| L3 interconnect | For information about the interconnect configuration, see Chapter 13, Interconnect . |

13.2.4.2 Operational Modes Configuration

13.2.4.2.1 L3 Interconnect Error Analysis Mode

13.2.4.2.1.1 Main Sequence: L3 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

[Figure 13-8](#) shows the software sequence required in most cases.

Figure 13-8. Typical Error Analysis Sequence

I3-013

Table 13-32 lists the register call summary for error analysis mode in the main sequence.

Table 13-32. Register Call Summary: Main Sequence – Error Analysis Mode

| Register Name | Register Name | Register Name |
|------------------------|-----------------------------------------|------------------------------------------|
| ERROR_LOG_k | L3_FLAGMUX_REGERR0 | L3_FLAGMUX_REGERR1 |
| L3_TARG_STDERRLOG_MAIN | CONTROL.CONTROL_SEC_ERR_STAT US_FUNC | CONTROL.CONTROL_SEC_ERR_STAT US_DEBUG |

Table 13-33 lists the subprocess call summary for error analysis mode in the main sequence.

Table 13-33. Subprocess Call Summary for Main Sequence – Error Analysis Mode

| Subprocess | Cross-Reference |
|-----------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| L4 interconnect error analysis | See Section 13.2.4.2.1, <i>L4 Interconnect Error Analysis Mode</i> . |
| L3 interconnect protection violation error identification | See Section 13.2.4.2.1.2, <i>Subsequence: L3 Interconnect Protection Violation Error Identification</i> . |
| L3 interconnect unsupported command/address hole error identification | See Section 13.2.4.2.1.3, <i>Subsequence: L3 Interconnect Unsupported Command/Address Hole Error Identification</i> . |
| L3 interconnect reset FLAGMUX and module | See Section 13.2.4.2.1.4, <i>Subsequence: L3 Interconnect Reset FLAGMUX and Module</i> . |

13.2.4.2.1.1 L3 Custom Error Identification

Table 13-34 demonstrates custom error identification.

Table 13-34. Custom Error Identification

| Step | Register | Value |
|----------------------------------------------------------|---------------------------------------------------------------------------|-------|
| IF: Is CustomError detected? | L3_TARG_STDERRLOG_MAIN[1] STDERRLOG_MAIN_ERRTYPE | = 0x1 |
| Read info field of the response packet. | L3_TARG_STDERRLOG_CUSTOMINFO_INFO[7:0] STDERRLOG_CUSTOMINFO_INFO | xxx |
| Read the address of the initiator that caused the error. | L3_TARG_STDERRLOG_CUSTOMINFO_MSTADDR[7:0] STDERRLOG_CUSTOMINFO_MSTADDR | xxx |
| Read the type of the operation (read/write). | L3_TARG_STDERRLOG_CUSTOMINFO_OPCODE[1:0] STDERRLOG_CUSTOMINFO_OPCODE | xxx |
| ENDIF | | |

NOTE: To understand why the target IP has returned an error, the user must read the target IP registers.

13.2.4.2.1.1.2 Subsequence: L3 Interconnect Protection Violation Error Identification

The procedure listed in Table 13-35 describes protection violation error identification and where it is logged in the control module registers. Two types of errors are logged: application errors and debug errors.

Table 13-35. Protection Violation Error Identification

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------------------------------------------|---------------------------------------------|-------|
| Read the burst violation. | ERROR_LOG_k[23] BLK_BURST_VIOLATION | xxx |
| Read the initiator ID. | ERROR_LOG_k[11:8] CONNID | xxx |
| Read the command that caused the error. | ERROR_LOG_k[7] MCMD | xxx |
| Read the address of the request that caused the error. | LOGICAL_ADDR_ERRLOG_k[31:12] SLVOFS_LOGICAL | xxx |
| IF: Is it an application error? | L3_FLAGMUX_REGERR0[17:0] REGERROR0 | = 0x0 |
| Read the status bits to see which module firewall has worked. | CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[20:0] | xxx |
| Clear the status bits. | CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[20:0] | xxx |

Table 13-35. Protection Violation Error Identification (continued)

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------------------|-----------------------------------------------------|-------|
| Clear the status bit. | L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG | 0x0 |
| ELSE IF | L3_FLAGMUX_REGERR1[17:0] REGERROR1 | = 0x1 |
| Read the status bits to see the module. | CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[20:0] | xxx |
| Clear the status bits. | CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[20:0] | xxx |
| Clear the status bit. | L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG | 0x0 |
| ENDIF | | |
| Clear the burst violation. | ERROR_LOG_k[23] BLK_BURST_VIOLATION | 0x0 |
| Clear the error status. | ERROR_LOG_k[21:17] REGION_START_ERRLOG | 0x00 |

13.2.4.2.1.1.3 Subsequence: L3 Interconnect Standard Error Identification

The procedure listed in [Table 13-36](#) describes the identification of standard errors inside the L3 interconnect. The standard errors are: unsupported command, address hole, and disconnect.

Table 13-36. L3 Standard Error Identification

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------------------|----------------------------------------------------------------------|-------|
| IF: Is an error detected? | L3_TARG_STDERRLOG_MAIN[18] STDERRLOG_MAIN_ERRCNT | = 0x1 |
| Read the corresponding flag. | L3_FLAGMUX_REGERR0[17:0] REGERROR0 | xxx |
| Read the corresponding flag. | L3_FLAGMUX_REGERR1[17:0] REGERROR1 | xxx |
| Localize the slave NIU that generated the error. | See Table 13-30 , <i>Interconnect Flag Mapping</i> . | |
| ELSE | | |
| Clear the error log. | L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_MAIN_CLRLOG | 0x0 |
| Clear the severity error status. | L3_TARG_STDERRLOG_SVRTSTDLVL[1:0] STDERRLOG_SVRTSTDLVL_0 | 0x2 |
| ENDIF | | |

13.2.4.2.1.1.4 Subsequence: L3 Interconnect FLAGMUX Configuration

The procedure listed in [Table 13-37](#) gives information about the configuration of FLAGMUX masks.

Table 13-37. FLAGMUX Configuration

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------------------------------|----------------------------------------------------------------------|-------|
| Set the FLAGMUX masks to mask an event. | L3_FLAGMUX_MASK0[17:0] MASK0 L3_FLAGMUX_MASK1[17:0] MASK1 | xxx |
| Read the REGERR bits to see if an error is recorded. | L3_FLAGMUX_REGERR0[17:0] REGERR0 L3_FLAGMUX_REGERR1[17:0] REGERR1 | xxx |
| Clear the slave NIU error log and the FLAGMUX error. | L3_TARG_STDERRLOG_MAIN[31] STDERRLOG_SVRTSTDLVL_0 | 0x2 |

13.2.5 L3 Interconnect Register Manual

13.2.5.1 L3 Register Group Summary

The registers in the L3 interconnect are divided into eight groups:

- Firewall registers [Table 13-39](#)
- HOST registers [Table 13-61](#)
- TARG registers [Table 13-97](#)
- PWR_DISK registers [Table 13-139](#)
- FLAGMUX registers [Table 13-163](#)
- BW registers [Table 13-178](#)
- RA registers [Table 13-193](#)
- STATCOLL registers [Table 13-201](#)

13.2.5.1.1 L3 Firewall Registers Summary and Description

Table 13-38. L3 Firewall Instance Summary

| Module Name | Base Address | Size |
|-------------------------|--------------|------|
| EMIF Firewall | 0x4A20 C000 | 4KB |
| GPMC Firewall | 0x4A21 0000 | 4KB |
| L3 RAM Firewall | 0x4A21 2000 | 4KB |
| SGX Firewall | 0x4A21 4000 | 4KB |
| ISS Firewall | 0x4A21 6000 | 4KB |
| Dual Cortex-M3 Firewall | 0x4A21 8000 | 4KB |
| DSS Firewall | 0x4A21 C000 | 4KB |
| SL2 Firewall | 0x4A21 E000 | 4KB |
| IVA-HD Firewall | 0x4A22 0000 | 4KB |
| Debug Firewall | 0x4A22 6000 | 4KB |
| L4-ABE Firewall | 0x4A22 8000 | 4KB |

13.3 L4 Interconnects

This section details the device L4 interconnects.

13.3.1 L4 Interconnect Overview

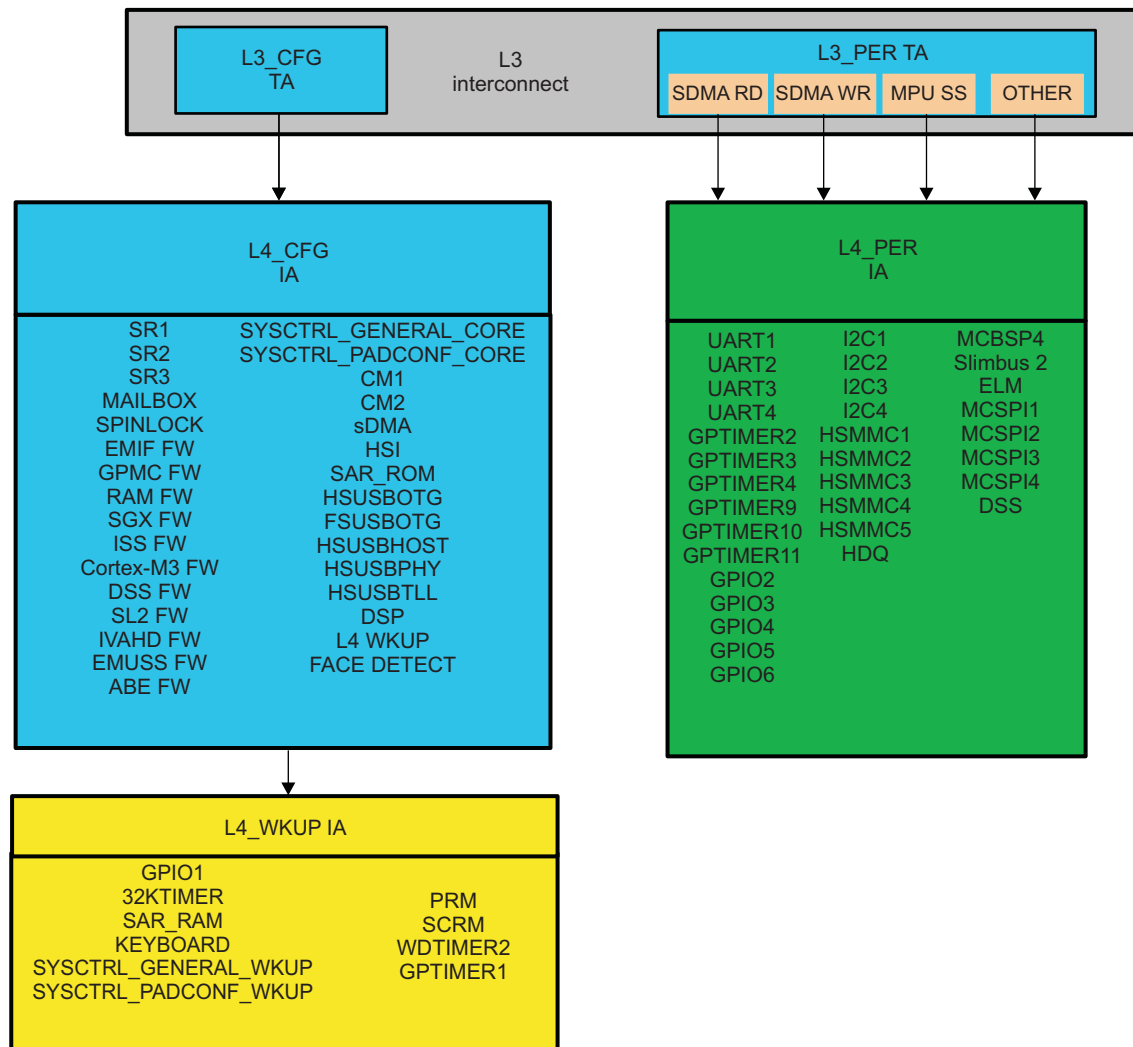

The device uses three separate L4 interconnect structures to connect peripheral modules. All L4s handle transfers with peripherals but are located in distinct power domains.

Figure 13-9 is an overview of the L4 interconnects and the peripherals attached to them.

The L4 interconnect is composed of the following interconnects:

- L4_CFG: Includes the majority of the configuration interface for L3 system modules and peripheral interconnect
- L4_PER: Includes the main peripherals that require sDMA access
- L4_WKUP: Includes peripherals attached to the WKUP power domain

Figure 13-9. L4 Interconnect Overview

icnt-013

The main features of the L4 interconnects are:

- From one to four 32-bit initiator ports for each L4 interconnect instance.
- 8-, 16-, or 32-bit data, single, or burst transactions
- Little endian

- Nonblocking architecture with fair arbitration between threads
- Target interfaces: Fully synchronous or divided synchronous
- L4_CFG and L4_PER frequency equal half of L3 frequency
- Protection logic that provides user-configurable access control to targets by each initiator
- Implementation of RFFs to support low-voltage dynamic power switching

13.3.2 L4 Interconnect Integration

Table 13-272 and Table 13-273 summarize the integration of the module in the device.

Table 13-272. Integration Attributes

| Module Instance | Attributes |
|-----------------|--------------|
| | Power Domain |
| L4_PER | PD_L4_PER |
| L4_CFG | PD_CORE |
| L4_WKUP | PD_WKUP |

13.3.3 L4 Interconnect Functional Description

13.3.3.1 Module Distribution

IAs and TAs provide the interface to connect the different modules to their associated interconnect.

Table 13-274 through Table 13-279 list all the modules and subsystems with their associated agents. The agents are listed for each L4 interconnect domain.

13.3.3.1.1 L4_PER Interconnect Agents

The L4_PER interconnect handles transfers only to peripherals in the PER power domain. Table 13-274 lists the PER TAs.

Table 13-274. L4 PER TAs

| Module Target Name | Description |
|--------------------|-----------------------------------------------|
| PER_TA_UART1 | UART port 1 module |
| PER_TA_UART2 | UART port 2 module |
| PER_TA_UART3 | UARTport 3 module |
| PER_TA_UART4 | UART port 4 module |
| PER_TA_GPTIMER2 | GPTIMER2 module |
| PER_TA_GPTIMER3 | GPTIMER3 module |
| PER_TA_GPTIMER4 | GPTIMER4 module |
| PER_TA_GPTIMER9 | GPTIMER9 module |
| PER_TA_GPTIMER10 | GPTIMER10 module |
| PER_TA_GPTIMER11 | GPTIMER11 module |
| PER_TA_DSS | Display subsystem configuration module |
| PER_TA_GPIO2 | General-purpose input/output 2 (GPIO2) module |
| PER_TA_GPIO3 | GPIO3 module |
| PER_TA_GPIO4 | GPIO4 module |
| PER_TA_GPIO5 | GPIO5 module |
| PER_TA_GPIO6 | GPIO6 module |
| PER_TA_I2C1 | I2C1 module |
| PER_TA_I2C2 | Multimaster I2C2 module |
| PER_TA_I2C3 | Multimaster I2C3 module |
| PER_TA_I2C4 | Multimaster I2C4 module |
| PER_TA_SLIMBUS2 | Silmbus 2 module |
| PER_TA_ELM | Error location module |
| PER_TA_MCBSP4 | McBSP4 module |
| PER_TA_MCSPI1 | McSPI1 module |
| PER_TA_MCSPI2 | MCSPi2 module |
| PER_TA_MCSPI3 | MCSPi3 module |
| PER_TA_MCSPI4 | MCSPi4 module |
| PER_TA_HSMMC1 | MMC controller 1 module |
| PER_TA_HSMMC2 | MMC controller 2 module |
| PER_TA_HSMMC3 | MMC controller 3 module |
| PER_TA_HSMMC4 | MMC controller 4 module |
| PER_TA_HSMMC5 | MMC controller 5 module |
| PER_TA_HDQ | Single-wire serial link low-rate module |

Four ports communicate between the L3 interconnect and the L4_PER interconnect to allow the L3 initiators to access the L4_PER targets. [Table 13-275](#) lists the L4_PER initiator TAs.

For the list of initiators authorized to access the L4 peripheral peripherals, see [Section 13.2.3.2.2, Connectivity Matrix](#).

Table 13-275. L4_PER IAs

| Module Initiator Name | Description |
|-----------------------|------------------------------------------------------------|
| PER_IA_0 | L3 system direct memory access (sDMA) RD interconnect port |
| PER_IA_1 | L3 sDMA WR interconnect port |
| PER_IA_2 | L3 MPU subsystem interconnect port |
| PER_IA_3 | L3 others interconnect port |

13.3.3.1.2 L4_CFG Interconnect Agents

The L4_CFG interconnect handles only transfers to peripherals in the core power domain. [Table 13-276](#) lists the TAs.

Table 13-276. L4_CFG TAs

| Module Target Name | Description |
|-----------------------------|------------------------------------|
| CFG_TA_SYSCTRL_GENERAL_CORE | System control general core module |
| CFG_TA_SYSCTRL_PADCONF_CORE | System control padconf core module |
| CFG_TA_CM1 | Clock manager 1 module |
| CFG_TA_CM2 | Clock manager 1 module |
| CFG_TA_SDMA | sDMA module |
| CFG_TA_HSI | HS SSI module |
| CFG_TA_SAR_ROM | Save-and-restore ROM |
| CFG_TA_HSUSBOTG | HS USB OTG module |
| CFG_TA_FSUSBHOST | FS USB OTG module |
| CFG_TA_HSUSBHOST | HS USB host module |
| CFG_TA_HSUSBPHY | HS USB PHY module |
| CFG_TA_HSUSBTLL | USB TTL module |
| CFG_TA_DSP | DSP subsystem |
| CFG_TA_SR1 | SmartReflex1 module |
| CFG_TA_SR2 | SmartReflex2 module |
| CFG_TA_SR3 | SmartReflex3 module |
| CFG_TA_MAILBOX | Mailbox module |
| CFG_TA_SPINLOCK | Spinlock module |
| CFG_TA_FACEDETECT | Face detect module |
| CFG_TA_EMIFFW | EMIF firewall |
| CFG_TA_GPMCFW | GPMC firewall |
| CFG_TA_OCMRAMFW | RAM firewall |
| CFG_TA_SGXFW | SGX firewall |
| CFG_TA_ISSF | ISS firewall |
| CFG_TA_CORTEXM3FW | Cortex-M3 firewall |
| CFG_TA_DSSFW | Display subsystem (DSS) firewall |
| CFG_TA_SL2FW | SL2 firewall |
| CFG_TA_IVAHDFW | IVA-HD firewall |
| CFG_TA_EMUSSF | EMU subsystem firewall |
| CFG_TA_ABEFW | ABE firewall |
| CFG_TA_L4WKUP | L4_WKUP connection |

A unique port, CFG_IA_0, communicates between the L3 interconnect and the L4_CFG interconnect to allow the L3 initiators to access the L4_CFG targets (see [Table 13-277](#)).

For the list of initiators authorized to access the L4_CFG peripherals, see [Section 13.2.3.2.2, Connectivity Matrix](#).

Table 13-277. L4_CFG IAs

| Module Initiator Name | Description |
|-----------------------|----------------------|
| CFG_IA_0 | L3 interconnect port |

13.3.3.1.3 L4_WKUP Interconnect Agents

The L4-WKUP interconnect handles transfers only to peripherals in the WKUP power domain. [Table 13-278](#) lists the TAs. [Table 13-279](#) lists the L4 WKUP initiator agents.

Table 13-278. L4_WKUP TAs

| Module Target Name | Description |
|------------------------------|------------------------------------------|
| WKUP_TA_GPIO1 | GPIO1 module |
| WKUP_TA_32KTIMER | 32-kHz timer module |
| WKUP_TA_SAR_RAM | Save-and-restore RAM |
| WKUP_TA_KEYBOARD | Keyboard module |
| WKUP_TA_SYSCTRL_GENERAL_WKUP | System control general WKUP module |
| WKUP_TA_SYSCTRL_PADCONF_WKUP | System control padconf WKUP module |
| WKUP_TA_PRM | Power reset management module |
| WKUP_TA_SCRM | System clock and reset management module |
| WKUP_TA_WDTIMER2 | WDTIMER2 module |
| WKUP_TA_GPTIMER1 | GPTIMER1 module |

Table 13-279. L4_WKUP IAs

| Module Initiator Name | Description |
|-----------------------|--------------------------|
| WKUP_IA_0 | L4_CFG interconnect port |

13.3.3.2 Power Management

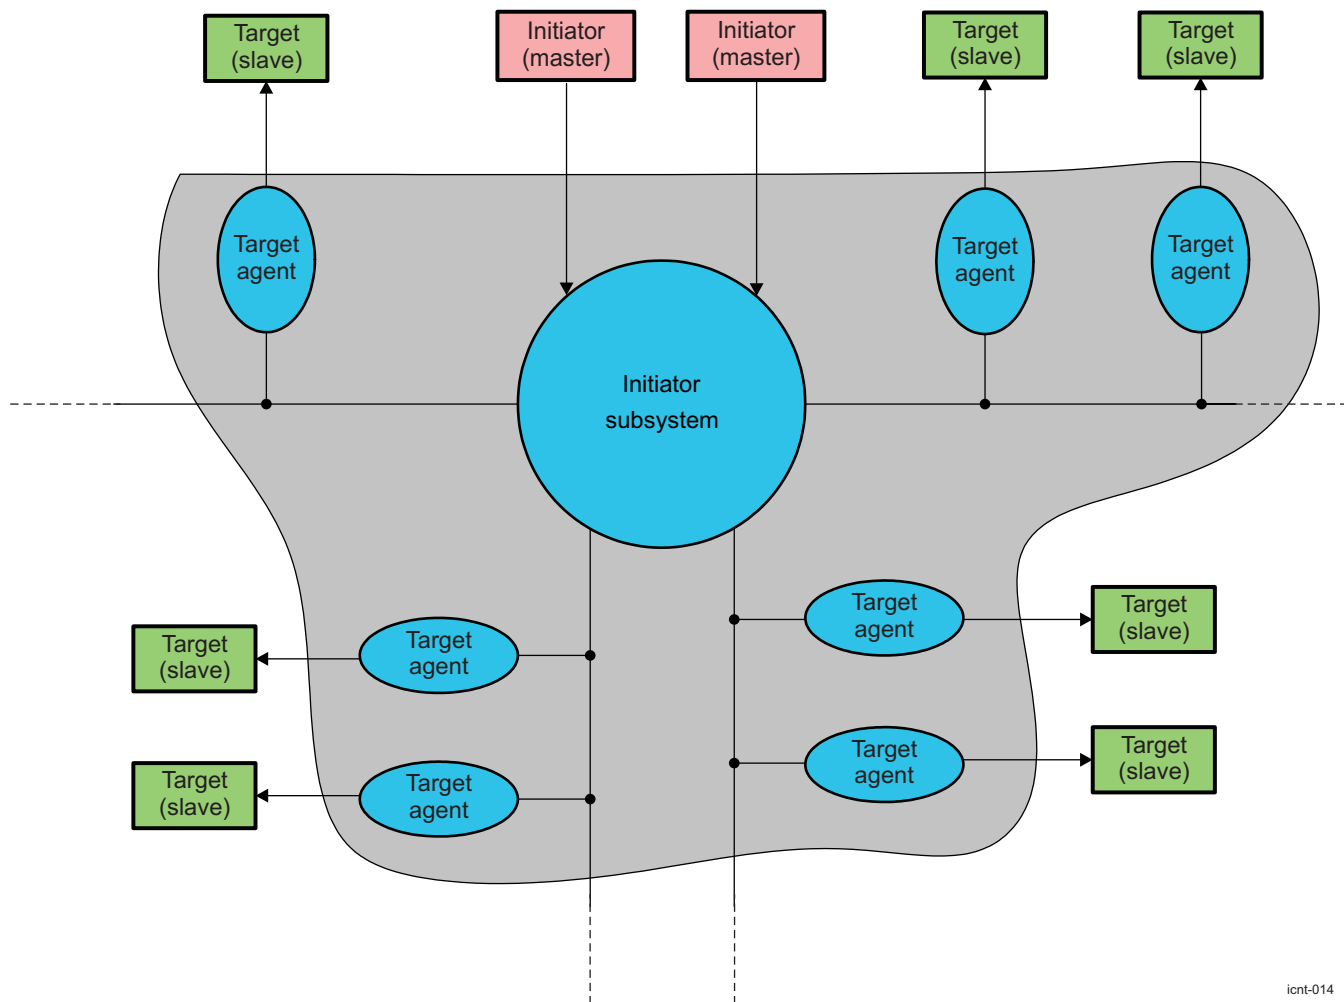

As part of the system-wide power-management scheme, the L4 interconnects go into IDLE state after receiving a request from the PRCM module after all commands are serviced. This function is handled by hardware. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

To reduce power consumption, each L4 interconnect automatically performs internal clock autogating. This is managed by hardware; no software configurations or settings are required.

Retention is performed on all software-accessible registers at IAs, TAs, and firewalls. This process prevents reconfiguration after a clock domain switches off. For more information, see [Chapter 3, Power, Reset, and Clock Management](#).

13.3.3.3 L4 Firewalls

[Figure 13-10](#) is an internal view of the L4 interconnects in the overall interconnect. This architecture, with one initiator subsystem centralizing all initiator master requests and distributing them to all target modules (peripherals), enables the L4 interconnect firewall functions to be centralized at the L4 initiator subsystem level. The L4 firewall filters the accesses based on the configurable protection groups defined in the L4 address protection (AP) registers. Each module or TA is assigned to a protection group. The configuration is also defined in the L4 AP and is programmable on a module-per-module basis.

Figure 13-10. L4 Initiator-Target Connectivity

icnt-014

NOTE: As Figure 13-10 shows, targets are attached to branches. Branches do not impact the function of the L4 interconnect but are present to simplify timing closure and reduce active power consumption.

Because of the large address spaces and the number of peripherals connected to an L4 interconnect, two parameters are used to set up access permission:

- Programmable groups for initiators
 - Eight protection groups for L4_PER and L4_CFG interconnect
- Segments divided into regions of 4KB
 - 100 regions for the L4_PER interconnect
 - 104 regions for the L4_CFG interconnect

NOTE:

- Regions and segments are present for the L4_WKUP interconnect but cannot be programmed.
- L4_WKUP protection is done through the L4_CFG interconnect.

Protection group members are TAs with the same protection settings. A region is programmed to allow access to a unique selectable protection group. For better protection, different regions are grouped into protection group regions and associated with a protection group member.

All L4 interconnect information, such as numbers of protection groups, regions, and segments, is available in the [L4_LA_INITIATOR_INFO_L](#) register.

13.3.3.3.1 Protection Group

A protection group is defined by its initiators and REQ_INFO is allowed. Two registers define these two settings:

- The CONNID_BIT_VECTOR field [L4_AP_PROT_GROUP_MEMBERS_k_L](#) is a 1-bit vector that defines which initiator belongs to a group. A protection group is accessible by an initiator when the bit position corresponding to its ConnID is set to 1 in the CONNID_BIT_VECTOR field. [Table 13-280](#) lists all the ConnID available at the L4 levels.
- The ENABLE field [L4_AP_PROT_GROUP_ROLES_k_L](#) lists all possible REQ_INFO combinations associated with the [L4_AP_PROT_GROUP_MEMBERS_k_L](#) register. Setting a Req bit in this register determines the initiators type of access. For more information, see [Section 13.2.3.7.3, L3 Firewall Functionality](#). Two REQ_INFOS are used in L4 interconnects: MReqDebug and MReqSupervisor.

NOTE: Permissions are identical for read and write accesses in L4 interconnect.

k indicates the protection group number.

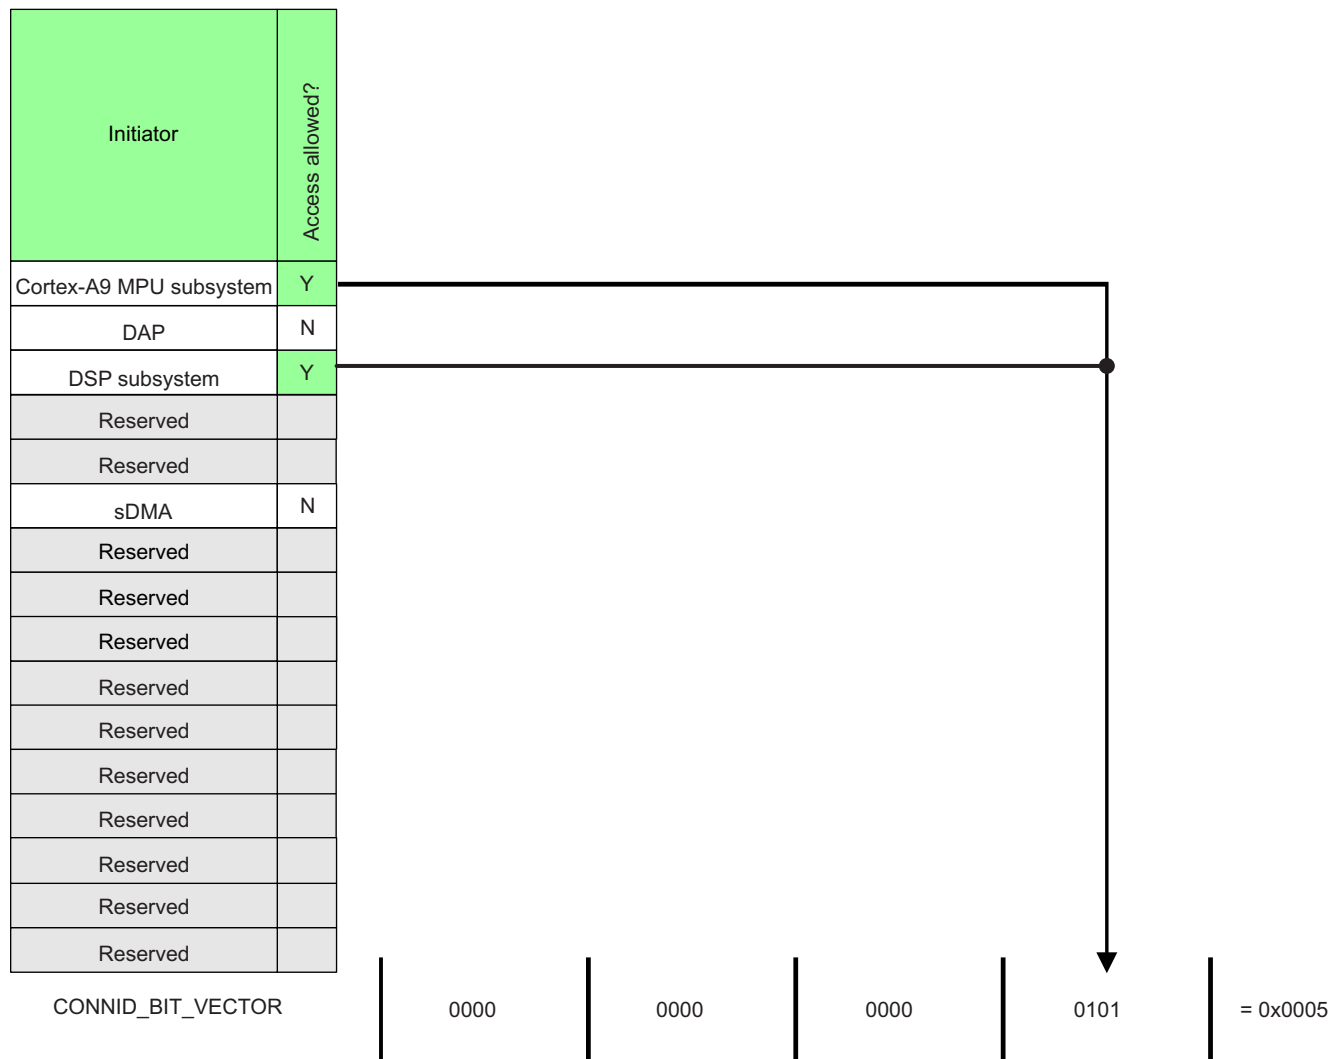

L indicates the region number.

Table 13-280. L4 ConnID Definition

| ConnID | Initiator |

| E | Reserved |
| F | Reserved |

Figure 13-11 is an example of CONNID_BIT_VECTOR.

Figure 13-11. Example of CONNID_BIT_VECTOR L4_AP_PROT_GROUP_MEMBERS_k

icnt-015

Setting bits 0 and 2 in the PROT_GROUP_ID_1 register defines a group initiator that can access targets in protection group 1, and includes the following:

- Cortex-A9 MPU subsystem
- DSP subsystem

Protection group 1 can be applied to multiple protection regions with no limitation. Each protection region that is configured with protection group 1 enables permission access only to the two initiators.

The L4_AP_REGION_I_H PROT_GROUP_ID field determines the region to which the protection group member is attached.

The values of some CONNID_BIT_VECTOR and ENABLE fields are exported by the SCM at reset or are user writable (see Table 13-403 for more information).

Table 13-281 and Table 13-282 list the default configuration of the various groups for each L4 interconnect. For each group, some modules/regions are associated with it with default initiator members.

Table 13-281. L4_PER Firewall Default Configuration

| Group | Default Modules Associated With Group | Register | Modifiability | Default Value |

13.3.3.3.2 Segments and Regions

The protection mechanism for L4 interconnects is based on a hierarchical segmentation, as shown in [Figure 13-12](#). By default, some regions are attached to specific protection group members. This specificity lets users set up the permission access to certain types of modules requiring the same access protection without managing region allocation.

Figure 13-12. L4 Segmentation

icnt-016

All interconnect address spaces are covered by regions. Table 13-283 through Table 13-285 list the module mapping with their addresses, region numbers, and default protection group allocated to them.

NOTE: Module refers to the configuration registers of the module.

TA refers to the interconnect configuration registers of the TA associated with the module.

Table 13-283. Region Allocations for L4_PER Interconnect

| Module | Region | Description |
|---------------|--------|-------------|
| L4_PER CONFIG | 0 | Firewall |
| | 1 | PER_IA_0 |

13.3.3.3 L4 Firewall Address and Protection Register Settings

Table 13-286 lists the settings of the AP registers relative to an L4 interconnect firewall. These values are computed based on the physical implementation of each L4 interconnect.

Table 13-286. L4 Firewall Register Description Overview

| Register Type | Register Name | Bits | Field | Description |
|---------------|----------------------------------|------|-------|------------------------------------------|
| Segment | L4_AP_SEGMENT_i_L ⁽¹⁾ | 23:0 | BASE | Segment base address |
| | L4_AP_SEGMENT_i_H ⁽¹⁾ | 4:0 | SIZE | Segment size equals to 2 ^{SIZE} |

⁽¹⁾ i = 0 to 1 for PER_AP
i = 0 to 6 for CFG_AP

Table 13-286. L4 Firewall Register Description Overview (continued)

| Register Type | Register Name | Bits | Field | Description |
|-------------------|-------------------------------------------------------------|--------|-------------------------------|--------------------------------------------------------------------------------|
| Protection groups | L4_AP_PROT_GROUP_MEMBERS_k_L ⁽²⁾ | 15:0 | CONNID_BIT_VECTOR | For L4ConnID, see Table 13-280 . |
| | L4_AP_PROT_GROUP_ROLES_k_L ⁽²⁾ | 31:0 | ENABLE | See Section 13.2.3.7.3 for REQ_INFO description ⁽³⁾ |
| Region setting | L4_AP_REGION_I_L ⁽⁴⁾ | 23:0 | BASE | Defines the base address of region with respect to its segment base address |
| | L4_AP_REGION_I_H ⁽⁴⁾ | 27:24 | SEGMENT_ID | Segment ID number of the region |
| | | 22:20 | PROT_GROUP_ID | Protection group member attached to the region |
| | | 19:17 | BYTE_DATA_WIDTH_EXP | Determines the number of byte in an access |
| | | 5:1 | SIZE | Size of the region equals to 2 ^{SIZE} |
| | 0 | ENABLE | Enables the region protection | |

⁽²⁾ k = 0 to 7 for PER_AP
k = 0 to 7 for CFG_AP

⁽³⁾ For L interconnects, only MReqDebug and MReqSupervisor are available.

⁽⁴⁾ I = 0 to 96 for PER_AP
I = 0 to 113 for CFG_AP

13.3.3.4 L4 Error Detection and Reporting

13.3.3.4.1 IA and TA Error Detection and Logging

The L4 interconnect provides mechanisms for handling internally detected errors or errors reported by modules attached to the L4 target ports.

NOTE: L4_IA denotes the IA for all L4 interconnects: L4_PER, L4_CFG, and L4_WKUP.

L4_TA denotes the TA for all L4 interconnects: L4_PER, L4_CFG, and L4_WKUP.

The L4 interconnects handle four types of errors:

- No target core found or address hole, detected and logged at IA
- Unsupported command, detected and logged at IA
- Protection violation, detected and logged at IA (see [Section 13.3.3.3, L4 Firewalls](#))
- Target does not service a request before a time-out expires. The error is detected and logged at TA (see [Section 13.3.3.4.2, Time-Out](#)).

[Table 13-287](#) lists the value of the [L4_IA_ERROR_LOG_L\[25:24\]](#) CODE bit field stored when an error occurs.

Table 13-287. L4 CODE Bit Field Definition

| CODE (bits 1:0) | Error Type | REQ_INFO | Secondary | ConnID | CMD |
|-----------------|----------------------|----------|-----------|--------|-----|
| 0 | No error | | | | |
| 1 | Unsupported command | x | x | x | x |
| 2 | Address hole | x | x | x | x |
| 3 | Protection violation | x | | x | x |

- No target core found/address hole: This error indicates that a request was addressed to a hole in the L4 address map. When this error occurs, an in-band error response is returned to the L3 level. The error is also logged into the [L4_IA_AGENT_STATUS_L\[27\]](#) INBAND_ERROR bit. Additionally, an address hole error code is logged to the [L4_IA_ERROR_LOG_L\[25:24\]](#) CODE bit field.
- Unsupported command: This error indicates that the command type of the request is not supported by

the accessed target register. The error is logged into the [L4_IA_AGENT_STATUS_L\[27\]](#) INBAND ERROR bit. An unsupported command error code is written to the [L4_IA_ERROR_LOG_L\[25:24\]](#) CODE bit field for the initiator interface.

- Protection violation: This error indicates that a request is not issued from an allowed initiator member or is issued with the inappropriate ReqInfo qualifiers associated with the target region. This error is reported using an in-band error and is written to the [L4_IA_AGENT_STATUS_L\[27\]](#) INBAND_ERROR bit. A protection violation error code is saved into the [L4_IA_ERROR_LOG_L\[25:24\]](#) CODE bit field for the same initiator interface. A protection violation is also logged in the [L4_IA_AGENT_STATUS_L\[31\]](#) PROT_ERROR_SECONDARY or [30] PROT_ERROR_PRIMARY bit when in debug or applicative mode, respectively.

The [L4_IA_ERROR_LOG_L\[30\]](#) SECONDARY bit indicates whether the error occurred in application or debug.

The [L4_IA_ERROR_LOG_H\[15:0\]](#) REQ_INFO bit field returns the type access (REQ_INFO qualifier) that caused the error.

The [L4_IA_ERROR_LOG_L\[11:8\]](#) CONNID bit field returns the ID of the initiator that caused the error.

The [L4_IA_ERROR_LOG_ADDR_L\[31:0\]](#) register logs the address for error conditions.

A [L4_IA_ERROR_LOG_L\[31\]](#) MULTI bit is asserted when multiple errors are detected. In this case, the error code corresponds to the first error that occurs.

13.3.3.4.2 Time-Out

A time-out mechanism can be enabled at the interconnect level and on a per-target basis. If the mechanism is enabled for a TA and interconnect and commands are not accepted or responses are not returned within the expected delay, the L4 interconnect generates an error event.

NOTE: The time-out mechanism is not available on the L4_WKUP interconnect, but L4_WKUP timeouts are detected in CFG_TA_L4WKUP of the L4_CFG interconnect.

The error is logged in the [L4_TA_AGENT_STATUS_L\[8\]](#) REQ_TIMEOUT bit. The affected TA enters an error state that causes it to send an error response to any new request targeted at it. To recover from this state, the TA must be reset by the system software. The time-out is counted starting from the moment a command is presented to the target, regardless of the target response to this command.

The L4 interconnect implements a centralized time-base circuit that broadcasts a set of four periodic pulse signals to all connected TAs. The time-base circuit offers four possible sets of four time-base signals. Selection is done by programming the [L4_LA_NETWORK_CONTROL_L\[10:8\]](#) TIMEOUT_BASE bit field.

The selected time-base signals are available at any TA. Each TA can be programmed to refer to one of these four time-base signals, using the [L4_TA_AGENT_CONTROL_L\[10:8\]](#) REQ_TIMEOUT bit field. These four signals are referred to as 1X time-base, 4X time-base, 16X time-base, and 64X time-base.

Table 13-288 lists all values in number of L4 clock cycles.

Table 13-288. L4 Time-Out Link and TA Programming

| | | L4_TA_AGENT_CONTROL_L REQ_TIMEOUT[2:0] | | | |
|--------------------------------------------------------------|----------------------------------------|-----------------------------------------------------------|--------|--------|---------|
| L4_LA_NETWORK_CONTROL_L TIMEOUT_BASE[2:0] | 0 | 1 | 2 | 3 | 4 |
| 0 | All L4 time-out features are disabled. | | | | |
| 1 | Locally disabled | 64 | 256 | 1024 | 4096 |
| 2 | | 256 | 1024 | 4096 | 16,384 |
| 3 | | 1024 | 4096 | 16,384 | 65,536 |
| 4 | | 4096 | 16,384 | 65,536 | 262,144 |

The default reset value is 0x2 for REQ_TIMEOUT and 0x4 for TIMEOUT_BASE, implying 16,384 clock cycles.

A time-out condition is detected when the command acceptance or the response is not received after a delay of from one to three time-base periods.

Example:

- L4 frequency = 65 MHz
- TIMEOUT_BASE = 4 in the [L4_LA_NETWORK_CONTROL_L](#) register
- REQ_TIMEOUT = 2 in the [L4_TA_AGENT_CONTROL_L](#) for TA A
- REQ_TIMEOUT = 4 in the [L4_TA_AGENT_CONTROL_L](#) for TA B

At agent A, the time-base unit is 16,384 cycles. A time-out is issued when a request to the attached module is not accepted, or no response is sent after a delay of 252 μ s to 756 μ s.

At agent B, the time-base unit is 262,144 cycles. A time-out is issued when a request to the attached module is not accepted or no response is sent after a delay of 4 ms to 12 ms.

On detection of a time-out condition, the TA logs the error in the [L4_TA_AGENT_STATUS_L\[8\]](#) REQ_TIMEOUT bit, and it also reports the error to the IA, which forward it to the L3 interconnects.

After the time-out is detected and logged, the behavior of the attached module is ignored. A new request targeting the module arriving at the timed-out TA receives an error response. If the request is addressed to the agent internal registers, it is processed normally.

To recover from a time-out error, software is assumed to first reset the faulty module and then the TA using the [L4_TA_AGENT_CONTROL_L\[0\]](#) OCP_RESET bit.

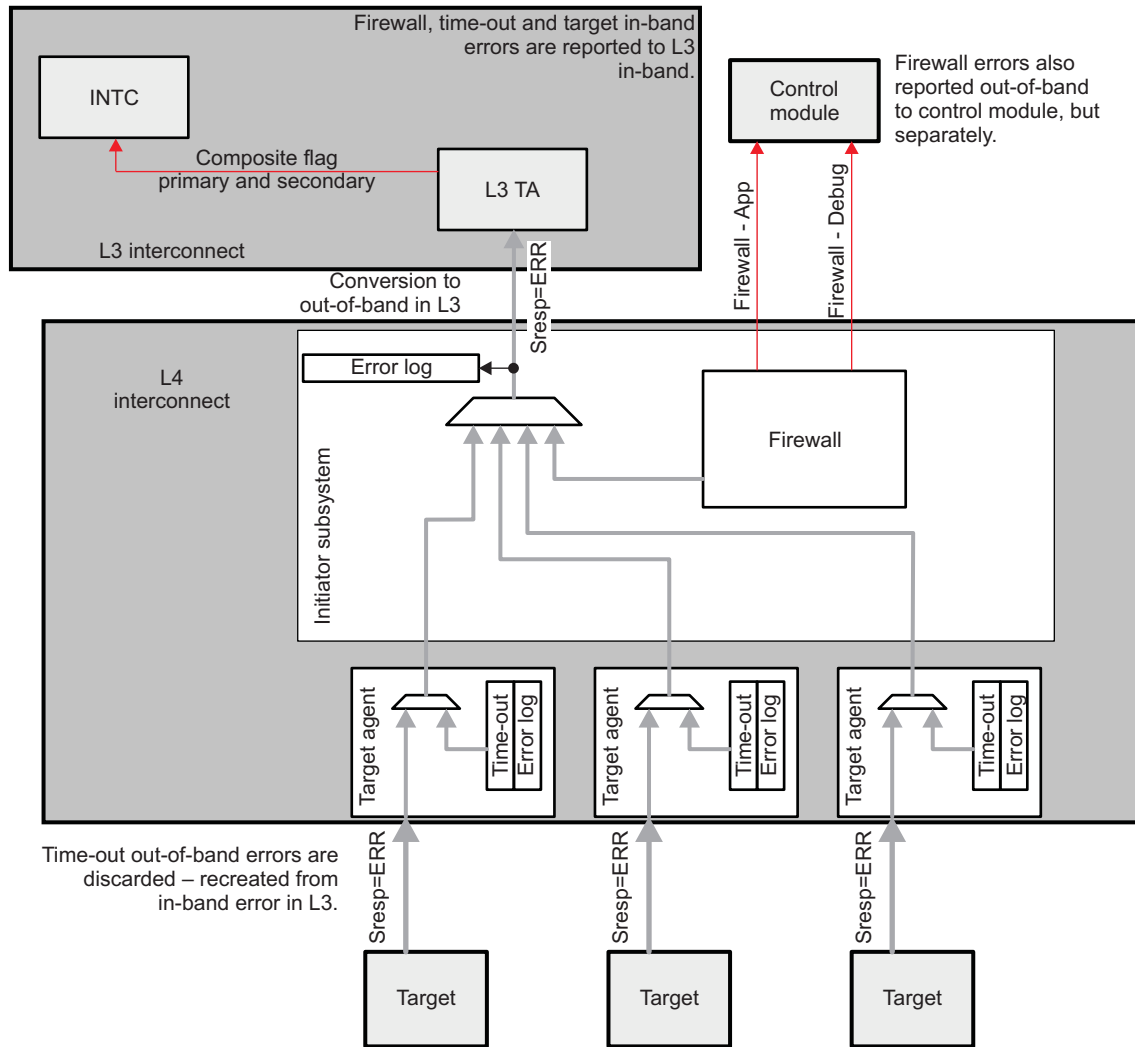

13.3.3.4.3 Error Reporting

[Figure 13-13](#) shows the error-reporting scheme used in the L4 interconnects. All L4 in-band errors are reported to their respective L3 TA, where errors are converted in an out-of band error signal (the L3 applicative and debug composite flags) going to the L3 Interrupt controllers.

Two levels of mask are present to report the error at INTC level:

- At the applicative and debug composite flag, to enable interrupt reporting, the following bits must be set:
 - L4 CFG in [L3_CLK1_FLAG_MASK_0\[3\]](#) and [L3_CLK1_FLAG_STATUS_1\[3\]](#)
 - L4 PER in [L3_CLK2_FLAG_MASK_0\[17\]\[16\]\[15\]\[6\]](#) and [L3_CLK2_FLAG_STATUS_1\[17\]\[16\]\[15\]\[6\]](#)
- At the L3 TA level, see [Section 13.2](#), *L3 Interconnect*.

Figure 13-13. L4 Error Reporting

icnt-017

13.3.3.4.4 Error Recovery

Writing 1 to the `L4_TA_AGENT_CONTROL_L[0] OCP_RESET` bit initiates the software reset period. Software reset must be asserted for at least 16 cycles of the target module interface clock, which can be a divided clock with respect to the L4 clock.

During the software reset period:

- Requests sent to the target module receive error responses. Therefore, if the faulty request is part of a DMA transfer, it is necessary to stop the DMA to prevent unwanted errors.
- Requests sent to the TA register block are processed as usual.
- The `L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT` status bit is cleared.

Writing 0 to the `L4_TA_AGENT_CONTROL_L[0] OCP_RESET` bit terminates the software reset period.

The attached module must then be reset to complete the recovery.

13.3.3.4.5 Firewall Error Logging in the Control Module

When a protection violation occurs, an interrupt is sent to the INTCs (if enabled). An in-band error is sent back to L3 IA and an out-band error can also be logged in the CONTROL.CONTROL_SEC_ERR_STATUS register in the system control module (SCM). These out-band errors are enabled/disabled at the L4 IA level by setting the L4_IA_AGENT_CONTROL_L[31][30] PROT_ERROR_SECONDARY_REP or PROT_ERROR_PRIMARY_REP bit to 1 for debug and application mode, respectively.

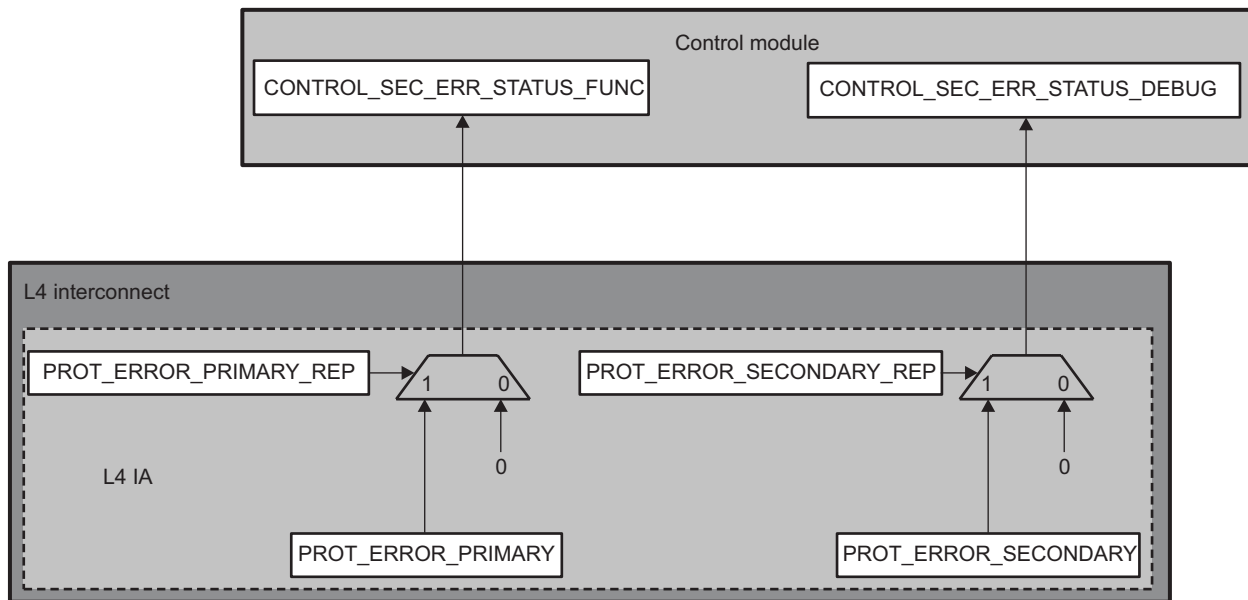

At the control module level, two logging registers are used, depending on the mode:

- In application mode or primary error reporting:
 - CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[16] = L4_CFG protection violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_FUNC[17] = L4_PER protection violation
- In debug mode or secondary error reporting:
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[16] = L4_CFG protection violation
 - CONTROL.CONTROL_SEC_ERR_STATUS_DEBUG[17] = L4_PER protection violation

NOTE: The CONTROL.CONTROL_SEC_ERR_STATUS_XXX registers are only readable.

Figure 13-14 shows the global protection error reporting to at the control module.

Figure 13-14. Protection Violation Out-of-Band Error Reporting

13.3.4 L4 Interconnect Programming Guide

13.3.4.1 L4 Interconnect Low-level Programming Models

This section describes the low-level hardware programming sequences for configuring and using the L4 interconnect module.

13.3.4.1.1 Global Initialization

13.3.4.1.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the L4 interconnect module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the L4 interconnect. For more information, see [Section 13.3.2, L4 Interconnect Integration](#).

Table 13-289. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| PRCM | For more information about the configuration of the module, see Chapter 3, Power, Reset, and Clock Management . |
| Control module | For more information about the configuration of the module, see Chapter 18, Control Module . |
| MPU INTC | The MPU INTC must be configured to enable the interrupts from L4 interconnect module. See Chapter 17, Interrupt Controllers . |
| sDMA | For more information about the configuration of the sDMA, see Chapter 16, sDMA . |
| L3 interconnect | For more information about the interconnect configuration, see Chapter 13, Interconnect . |

13.3.4.1.2 Operational Modes Configuration

13.3.4.1.2.1 L4 Interconnect Error Analysis Mode

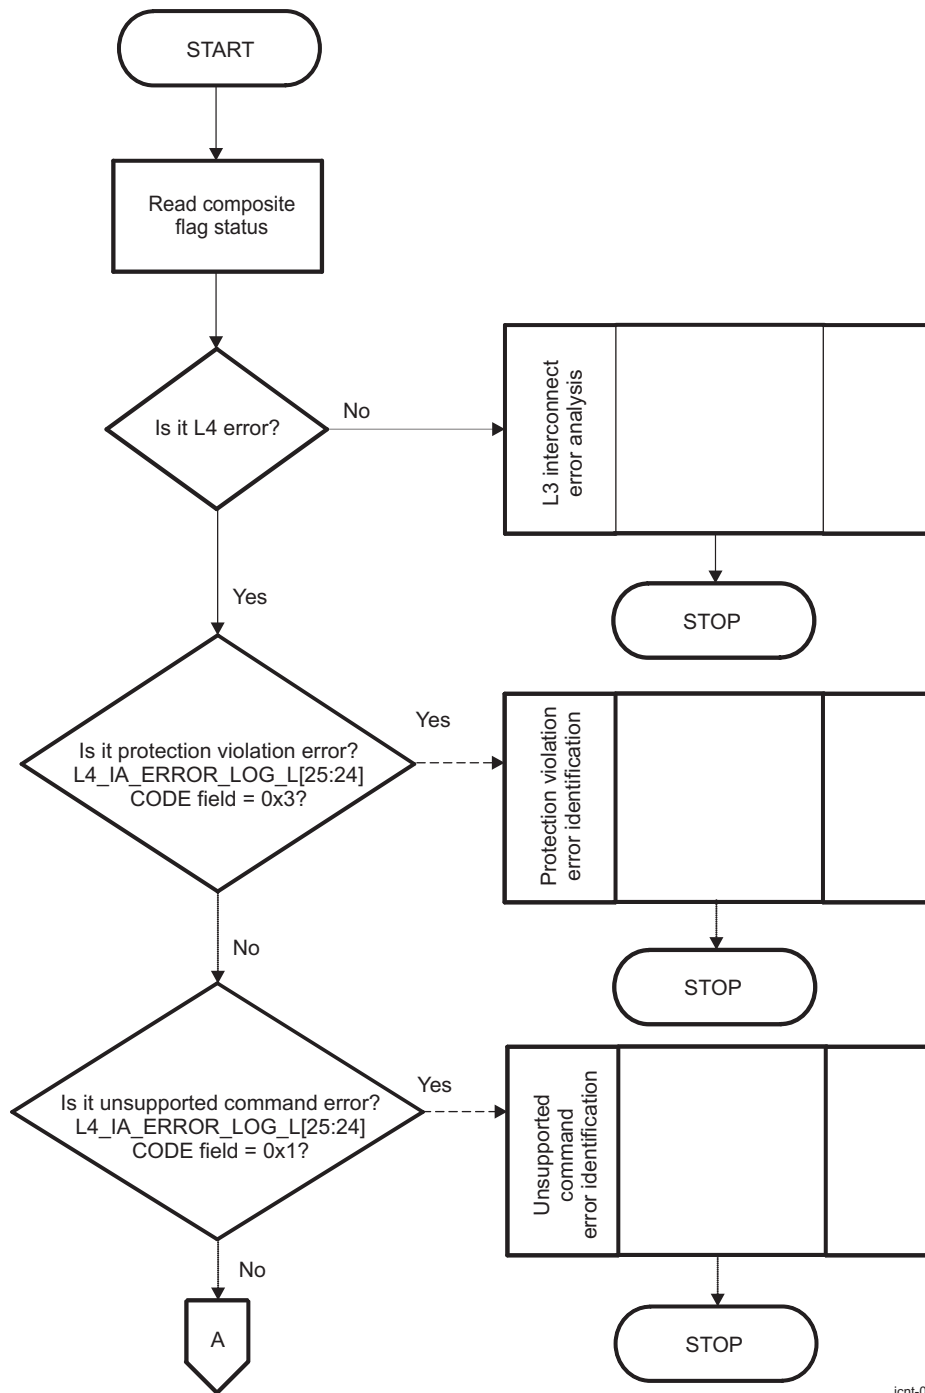

13.3.4.1.2.1.1 Main Sequence: L4 Interconnect Error Analysis Mode

The information required to analyze an error source is logged in several registers. The number of registers to access depends on the error source.

[Figure 13-15](#) and [Figure 13-16](#) show the software sequence required in most cases.

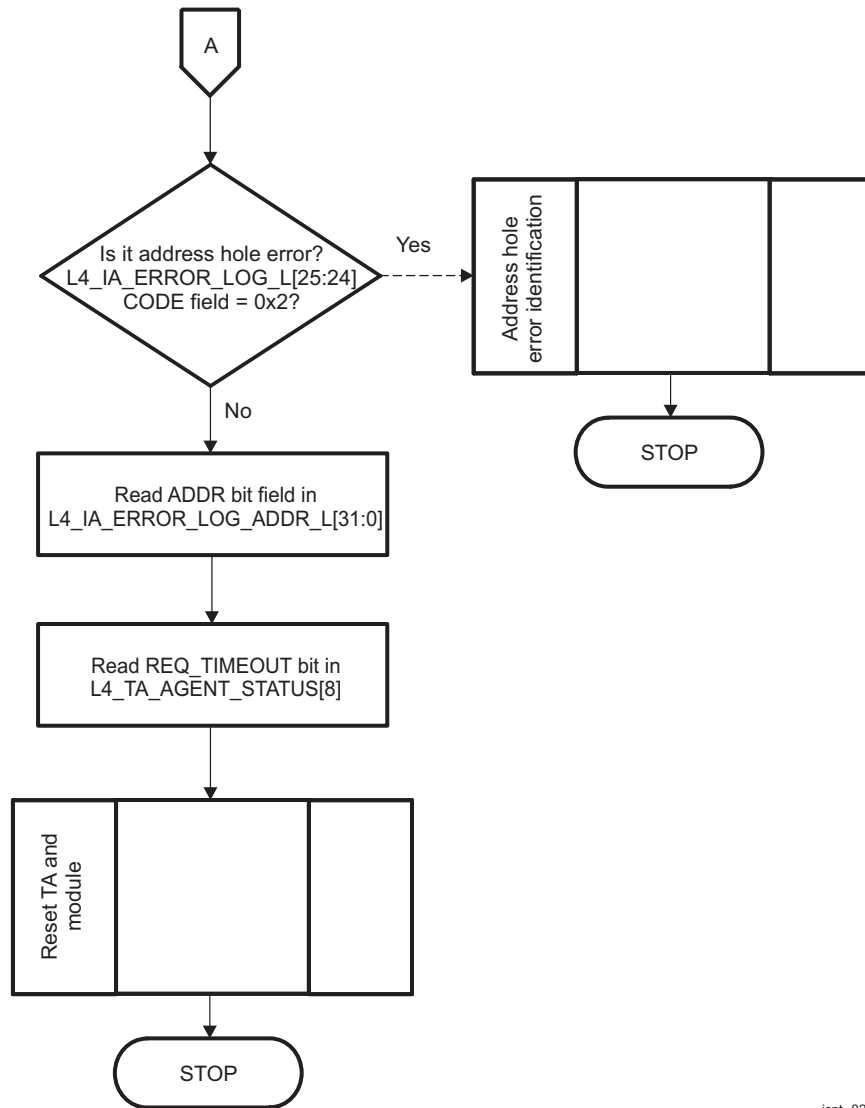

[Table 13-290](#) and [Table 13-291](#) show the main sequence for error analysis mode and its subprocess call summary, respectively.

Figure 13-15. Typical Error Analysis Sequence

icnt-019

Figure 13-16. Typical Error Analysis Sequence

icnt-020

Table 13-290. Main Sequence – Error Analysis Mode

| Register Name | Register Name | Register Name |
|-----------------------|--------------------------------------|---------------------------------------|
| L4_IA_ERROR_LOG_L | L4_IA_ERROR_LOG_ADDR_L | L4_IA_AGENT_STATUS_L |
| L4_IA_AGENT_CONTROL_L | CONTROL.CONTROL_SEC_ERR_STAT_US_FUNC | CONTROL.CONTROL_SEC_ERR_STAT_US_DEBUG |
| L4_TA_AGENT_STATUS_L | | |

Table 13-291. Subprocess Call Summary for Main Sequence – Error Analysis Mode

| Subprocess | Cross-Reference |
|-----------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| L3 interconnect error analysis | Section 13.2.3.8, L3 Interconnect Error Handling |
| L4 interconnect protection violation error identification | Section 13.3.4.1.2.1.2, Subsequence: L4 Interconnect Protection Violation Error Identification |
| L4 interconnect unsupported command/address hole error identification | Section 13.3.4.1.2.1.3, Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification |
| L4 interconnect reset TA and module | Section 13.3.4.1.2.1.4, Subsequence: L4 Interconnect Reset TA and Module |

13.3.4.1.2.1.2 Subsequence: L4 Interconnect Protection Violation Error Identification

This procedure describes the protection violation error identification (see [Table 13-292](#)).

Table 13-292. Protection Violation Error Identification

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------------------------|--------------------------------------------------|-------|
| Read multiple errors detection. | L4_IA_ERROR_LOG_L[31] MULTI | |
| Read initiator ID. | L4_IA_ERROR_LOG_L[11:8] CONNID | |
| Read command that cause the error. | L4_IA_ERROR_LOG_L[2:0] CMD | |
| Read address of request that caused the error. | L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR | |
| IF: Is it a primary error? | L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY | =0x1 |
| Read status bits. | CONTROL.CONTROL_SEC_ERR_STATUS_FUN C[17:16] | |
| Write 1 to clear status bits. | CONTROL.CONTROL_SEC_ERR_STATUS_FUN C[17:16] | 0x3 |
| Write 1 to clear IA status bit. | L4_IA_AGENT_STATUS_L[30] PROT_ERROR_PRIMARY | 0x1 |
| ELSE | | |
| Read status bits. | CONTROL.CONTROL_SEC_ERR_STATUS_DEB UG[17:16] | |
| Write 1 to clear status bits. | CONTROL.CONTROL_SEC_ERR_STATUS_DEB UG[17:16] | 0x3 |
| Write 1 to clear IA status bit | L4_IA_AGENT_STATUS_L[31] PROT_ERROR_SECONDARY | 0x1 |
| ENDIF | | |
| Write 1 to clear multiple errors detection. | L4_IA_ERROR_LOG_L[31] MULTI | 0x1 |
| Write 1 to clear in-band error status. | L4_IA_AGENT_STATUS_L[24] INBAND_ERROR | 0x1 |

13.3.4.1.2.1.3 Subsequence: L4 Interconnect Unsupported Command/Address Hole Error Identification

This procedure describes the identification of unsupported command/address hole error (see [Table 13-293](#)).

Table 13-293. Unsupported Command/Address Hole Error Identification

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------------------------|---------------------------------------|-------|
| Read multiple errors detection. | L4_IA_ERROR_LOG_L[31] MULTI | |
| Read initiator ID. | L4_IA_ERROR_LOG_L[11:8] CONNID | |
| Read command that caused the error. | L4_IA_ERROR_LOG_L[2:0] CMD | |
| Read address of request that caused the error. | L4_IA_ERROR_LOG_ADDR_L[31:0] ADDR | |
| Read secondary status. | L4_IA_ERROR_LOG_L[30] SECONDARY | |
| Write 1 to clear secondary status. | L4_IA_ERROR_LOG_L[30] SECONDARY | 0x1 |
| Write 1 to clear multiple errors detection. | L4_IA_ERROR_LOG_L[31] MULTI | 0x1 |
| Write 1 to clear inband error status. | L4_IA_AGENT_STATUS_L[24] INBAND_ERROR | 0x1 |

13.3.4.1.2.1.4 Subsequence: L4 Interconnect Reset TA and Module

This procedure resets the TA and module (see [Table 13-294](#)).

Table 13-294. Reset TA and Module

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------------------------|--------------------------------------|-------|
| Reset TA. | L4_TA_AGENT_CONTROL_L[0] OCP_RESET | 0x1 |
| Wait until target module clock = 16 cycles. | | |

Table 13-294. Reset TA and Module (continued)

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------------------------|------------------------------------------------------------|-------|
| Write 0 to clear TA time - out status. | L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT | 0x0 |
| Write 0 to clear TA reset. | L4_TA_AGENT_CONTROL_L[0] OCP_RESET | 0x0 |
| Reset the attached module. ⁽¹⁾ | | |

⁽¹⁾ For more information, see the respective module chapter.

13.3.4.1.2.2 L4 Interconnect Time-Out Configuration Mode

13.3.4.1.2.2.1 Main Sequence: L4 Interconnect Time-Out Configuration Mode

This procedure describes the time-out configuration sequence (see [Table 13-295](#)).

Table 13-295. Time-Out Configuration

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------------------------|---------------------------------------------------------------|-------|
| Disable time-out. | L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE | 0x0 |
| Clear TA time-out error status. ⁽¹⁾ | L4_TA_AGENT_STATUS_L[8] REQ_TIMEOUT | 0x1 |
| Set time-out at TA level. ⁽¹⁾ | L4_TA_AGENT_CONTROL_L[10:8] REQ_TIMEOUT | xxx |
| Set time-out base. | L4_LA_NETWORK_CONTROL_L[10:8] TIMEOUT_BASE | xxx |

⁽¹⁾ Must be done for each TA.

13.3.4.1.2.3 L4 Interconnect Firewall Configuration Mode

13.3.4.1.2.3.1 Main Sequence: L4 Interconnect Firewall Configuration Mode

This procedure describes the firewall configuration sequence (see [Table 13-296](#)).

Table 13-296. Firewall Configuration

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------------------------------|-------------------------------------------------------------------------|-------|
| Define the members of protection group k. ⁽¹⁾ | L4_AP_PROT_GROUP_MEMBERS_k_L[15:0] CONNID_BIT_VECTOR | xxx |
| Define the access type of a protection group k. ⁽¹⁾ | L4_AP_PROT_GROUP_ROLES_k_L[15:0] ENABLE | xx |
| Set region affiliation to protection group. ⁽²⁾ | L4_AP_REGION_I_L[22:20] PROT_GROUP_ID | xxx |

⁽¹⁾ Must be done for each protection group.

⁽²⁾ Must be done for each region.

13.3.5 L4 Interconnects Register Manual

Table 13-297 through Table 13-299 list all L4 register blocks for IA, TA, AP, and LA. Each module instance is shown with the module register mapping and bit and bit field definitions.

13.3.5.1 L4 Interconnects Instance Summary

Table 13-297. L4_PER Instance Summary

| Module Name | L3 Base Address | Size |
|------------------|-----------------|------|

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | CLOCK_GATE_DISABLE | | RESERVED | | THREAD0_PRI | | RESERVED | | | | | | | | EXT_CLOCK | | RESERVED | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:25 | RESERVED | Read returns 0. | R | 0x00 |
| 24 | CLOCK_GATE_DISABLE | When set to 1 this field disables all clock gating. | RW | 0 |
| 23:21 | RESERVED | Read returns 0. | R | 0x0 |
| 20 | THREAD0_PRI | Sets thread priority. If the field is set to 0, the default, all initiator threads are treated the same. Setting the THREAD0_PRI field to 1 assigns a higher arbitration priority to thread 0 of the first initiator OCP interface. To avoid starvation, arbitration is imposed by the initiator subsystem. When multiple requests from different initiator threads are dispatched to targets simultaneously, the oldest request is dispatched first. If thread 0 is assigned a higher priority, a request on thread 0 always wins arbitration. Assigning thread 0 of the first initiator OCP the highest priority on a request or response can result in the starvation of other threads. | R | 1 |
| 19:9 | RESERVED | Read returns 0. | R | 0x000 |
| 8 | EXT_CLOCK | When set to 1, the ext_clk_off_i signal on the initiator subsystem instructs the entire L4 to shut off. | R | 1 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-----------------|------|-------|
| 7:0 | RESERVED | Read returns 0. | R | 0x00 |

- [Operational Modes Configuration: \[1\]](#)
- [L4 Address Protection \(L4 AP\) Register Summary: \[2\]](#)

Table 13-413. L4_AP_REGION_I_H

| | | | |
|-------------------------|----------------------------------------------------------------|--------------|-------------------------|
| Address Offset | 0x304 + (0x08*I) | Index | I = 0 to 99 for CORE_AP |
| Physical address | 0x4800 0304 + (0x08*I) 0x4A00 0304 + (0x08*I) | | |
| Description | Define the size, protection group and segment ID of the region | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|------------|----|----|----|----------|---------------|----|----|----|---------------------|----|----|----|----------|----|----|----|----|---|---|---|------|---|---|---|--------|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Reserved | | | | SEGMENT_ID | | | | Reserved | PROT_GROUP_ID | | | | BYTE_DATA_WIDTH_EXP | | | | Reserved | | | | | | | | SIZE | | | | ENABLE | | |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|------------------------------------------------|------|---------------------------------------------------------------------|
| 31:28 | Reserved | Read returns 0 | R | 0x0 |
| 27:24 | SEGMENT_ID | The segment associated to the region. | R | See Table 13-415 and Table 13-416 . |
| 23 | Reserved | Read returns 0. | R | 0 |
| 22:20 | PROT_GROUP_ID | The protection group associated to the region. | RW | See Table 13-415 and Table 13-416 . |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------|---------------------------------------------------------------------------------------------------------|------|---------------------------------------------------------------------|
| 19:17 | BYTE_DATA_WIDTH_EXP | The target data byte width is $2^{(\text{BYTE_DATA_WIDTH_EXP})}$ bytes. | R | See Table 13-415 and Table 13-416 . |
| 16:6 | Reserved | Read returns 0. | R | 0x0 |
| 5:1 | SIZE | Define the size of the region in bytes. 2^{SIZE} equals the region. | R | See Table 13-415 and Table 13-416 . |
| 0 | ENABLE | 0x0: Disable the region, no access allows 0x1: Enable the region, with access as define in registers | R | 0x1 |

Memory Subsystem

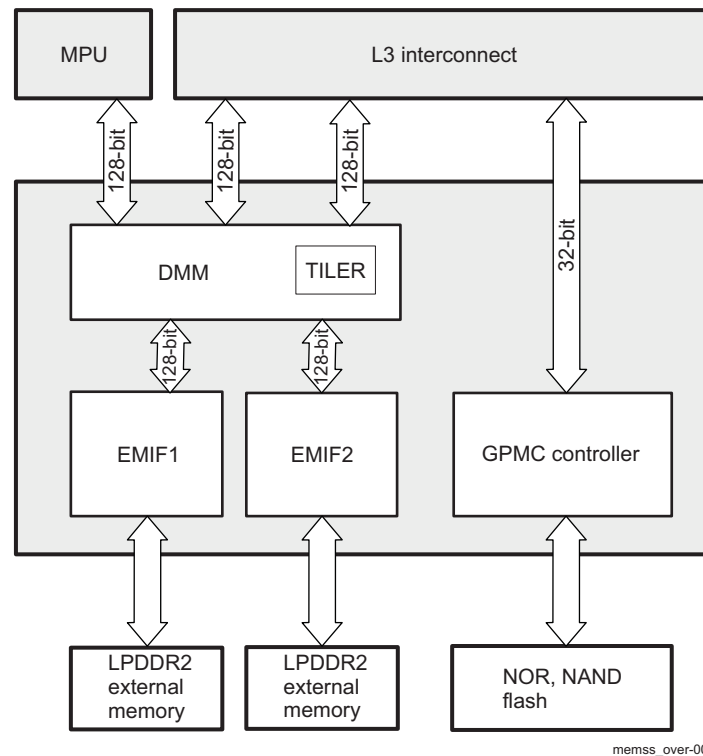

This chapter introduces the memory subsystem of the device.

| Topic | Page |
|----------------------------------------------|------|
| 15.1 Memory Subsystem Overview | 3200 |
| 15.2 Dynamic Memory Manager | 3205 |
| 15.3 EMIF Controller | 3285 |
| 15.4 General-Purpose Memory Controller | 3357 |
| 15.5 Error Location Module | 3497 |
| 15.6 On-Chip Memory (OCM) Subsystem | 3524 |

15.1 Memory Subsystem Overview

Figure 15-1 shows a functional diagram of all memory subsystems in the device.

Figure 15-1. Memory Subsystem Functional Diagram

15.1.1 DMM Overview

The dynamic memory manager (DMM) module is typically located immediately in front of the synchronous dynamic random access memory (SDRAM) memory controller, as shown in Figure 15-1.

In a broad sense, the DMM manages various aspects of memory accesses such as:

- Initiator-indexed priority generation
- Multizone SDRAM memory interleaving configuration
- Block object transfer optimization – tiling
- Centralized low-latency page translation – MMU-like feature

The dynamic qualifier for memory management highlights the software configurability, and hence the runtime nature, of the four aspects of memory management handled by the DMM.

15.1.1.1 DMM Features

From a functional perspective, the role of the DMM is to:

- Add initiator-based priority to any incoming requests
- Perform to/from tiling conversions of tiled requests
- Make on-the-fly basic transforms, such as quadrant rotations and mirroring
- Optionally, provide a low-latency page-based translation to handle memory fragmentation – MMU
- Distribute the traffic on all attached memory controllers according to the interleaving configuration

The DMM main features are:

- Programmable multizone DRAM memory mapping and interleaving configuration
- Programmable initiator-based request priority extension

- Multichannel memory transfer optimization
- Single SDRAM page request generation
- Low-latency interconnect port
- Page-grained address translation to manage memory fragmentation
- Automatic synchronized reloading of the address translation table

15.1.2 TILER Overview

The tiling and isometric lightweight engine for rotation (TILER) is a submodule of DMM (see [Figure 15-1](#)) and is therefore described in [Section 15.2, Dynamic Memory Manager](#).

The TILER is intended to improve bidimensional (tiled) block transfer efficiency. It is, therefore, a module aimed at:

- Primarily, efficient handling of 2-dimension (2D) data mapped in tiles, such as video or graphics macroblocks
- Optionally, managing the memory fragmentation and zero-copy physical frame-buffer swapping through a page-grained translation
- Making isometric (distance preserving) transforms, such as 90-, 180-, or 270-degree rotations, with a horizontal or vertical reflection

The lightweight qualifier of this engine highlights its limited support of isometric transforms, as:

- Rotation performs only basic quadrant rotations by some multiple of 90 degrees.
- Reflection is limited to horizontal and vertical flip.
- Translation is restricted to a 4-KB page granularity.

Written differently, the functionality of the TILER is to map a 2D virtually addressed interconnect request into one or more physically addressed interconnect requests by:

- Transforming the virtual address, data, and byte-enable to match the requested 0-, 90-, 180-, or 270-degree orientation in a tiled 2D addressing space
- Optionally translating the oriented tiled address by a page-specific vector to manage memory fragmentation and physical object aliasing

15.1.2.1 TILER Features

The main features of the TILER are:

- Efficiency improvement of 2D block access on SDRAMs
- Optimized interlaced access on tiled frames
- 2D virtual-to-physical address translation of SDRAM bidimensional objects to handle rotation
- Page-grained address translation to manage memory fragmentation and physical buffer aliasing
- Unlimited number of 2D tiled objects supported in any (0, 90, 180, or 270 degrees) orientation
- Full bandwidth use by minimizing the size of raster-based initiator buffers
- Optimization of multichannel memory transfers
- Interconnect request granularity balance (in X and Y directions)

15.1.3 EMIF Overview

The extended memory interface (EMIF) module is typically located near the DMM module, as shown in [Figure 15-1](#).

The EMIF provides connectivity between the device and LPDDR2-type memory. It manages data bus read/write accesses between external memories, the microprocessor unit (MPU), and the direct memory access (DMA) controller. It acts as the primary interface between SDRAM and all functional blocks, such as the ARM®, IVA-HD, imaging subsystem (ISS), GFX, and DMA controllers.

15.1.3.1 Main Features

The EMIF has the following capabilities:

- Supports JEDEC standard-compliant LPDDR2-SDRAM (S2 and S4) and LPDDR2-NVM devices
- 2-GB SDRAM address range over two chip selects (CSs) (configurable with the DMM; see [Section 15.2, Dynamic Memory Manager](#), for more information)
- Supports two independent CSs, with their corresponding register sets, and independent page tracking
- Both CSs must have the same memory type and size if they are both SDRAM or both nonvolatile memory (NVM). LPDDR2-SDRAM can be used in parallel with LPDDR2-NVM and can have a different size.
- Flexible address muxing scheme which permits choosing different bank-mapping allocation by configuring the bank, column, and row-address decoding ordering
- 16- or 32-bit data path to external SDRAM
- Supports LPDDR2 devices with 1, 2, 4, or 8 internal banks
- Supports the following data bus widths:
 - 128-bit level 3 (L3) interconnect data bus width
 - 16- and 32-bit SDRAM data bus width
- Supports the following CAS latencies: 3, 4, 5, 6, 7, and 8
- Supports 256-, 512-, 1024-, and 2048-word page sizes
- Supports the following burst lengths: 8
- Supports sequential burst type
- SDRAM auto-initialization from reset or configuration change
- Supports bank interleaving across both CSs if same memory type
- Supports self-refresh and precharge power-down modes for low power (per CS, manual entry/exit self-refresh, and deep power-down modes)
- Supports deep power-down mode for low power
- Supports partial array self-refresh and temperature-controlled self-refresh modes for low power. Temperature-controlled self-refresh is supported only for mobile SDRAM having an on-chip temperature sensor.
- Supports prioritized refresh
- Programmable SDRAM refresh rate and backlog counter
- Supports ZQ calibration
- Supports temperature monitoring

15.1.4 GPMC Overview

The general-purpose memory controller (GPMC) is a unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (available only in nonmuxed mode) burst NOR flash devices
- NAND flash
- Pseudo-SRAM devices

15.1.4.1 GPMC Features

The GPMC is the external memory controller of the device. The GPMC data access engine provides a flexible programming model for communication with all standard memories. The GPMC supports various accesses:

- Asynchronous read/write access
- Asynchronous read page access (4, 8, and 16 Word16)

- Synchronous read/write access
- Synchronous read/write burst access without wrap capability (4, 8, and 16 Word16)
- Synchronous read/write burst access with wrap capability (4, 8, and 16 Word16)
- Address/data-multiplexed access
- Little- and big-endian access

The GPMC can communicate with a wide range of external devices:

- External asynchronous or synchronous 8-bit wide memory or device (nonburst device)
- External asynchronous or synchronous 16-bit wide memory or device
- External 16-bit nonmultiplexed device with limited address range (2KB)
- External 16-bit address/data-multiplexed NOR flash device
- External 8-bit and 16-bit NAND flash device
- External 16-bit pseudo-SRAM (pSRAM) device

The main features of the GPMC are:

- 8- or 16-bit-wide data path to external memory device
- Supports up to eight CS regions of programmable size and programmable base addresses in a total address space of 1GB
- Supports transactions controlled by a firewall
- On-the-fly error code detection using the Bose-Chaudhuri-Hocquenghem (BCH) ($t = 4, 8, \text{ or } 16$) or Hamming code to improve the reliability of NAND with a minimum effect on software (NAND flash with 512-byte page size or greater)
- Fully pipelined operation for optimal memory bandwidth use
- External device clock provided from the L3 clock divided by 1, 2, 3, or 4
- Supports programmable autoclock gating when no access is detected
- Independent and programmable control signal timing parameters for setup and hold time on a per-chip basis. Parameters are set according to the memory device timing parameters, with a timing granularity of one L3 clock cycle.
- Flexible internal access time control (WAIT state) and flexible handshake mode using external WAIT pin monitoring
- Support bus keeping
- Support bus turnaround
- Prefetch and write posting engine associated with system DMA (sDMA) to achieve full performance from the AND device with minimum effect on NOR/SRAM concurrent access

NOTE: Page mode is available only in nonmultiplexed mode.

15.1.5 ELM Overview

NAND flash memories are dense and nonvolatile, but error-prone. Whenever NAND flash memories are read from, some level of error correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as bare NAND, the correction process is delegated to the memory controller.

The error location module (ELM) must be used in conjunction with the GPMC. The GPMC probes data read from an external NAND flash and uses them to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare area data field, with a maximum block size of 1023 bytes. Computation is based on the BCH algorithm. The ELM extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a configuration parameter. Error correction levels of 4, 8, and 16 bits are supported. The ELM relies on a static definition of the generator polynomial for each error correction level that corresponds to the generator polynomials defined in the GPMC. A larger number of errors can be detected, but the ELM cannot correct them all. The offending block is then tagged as uncorrectable.

When the error location process completes, an interrupt is triggered to inform a central processing unit (CPU) that its status can be checked. The error locations for the NAND page can be retrieved from the module through register accesses.

15.1.5.1 ELM Features

The ELM features:

- 4, 8, and 16 bits per 512-byte block error location based on BCH algorithm
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation when error location process completes:
 - When the full page has been processed in page mode
 - For each syndrome polynomial in continuous mode

15.1.6 OCM Overview

The on-chip memory (OCM) subsystem consists of the following OCM controllers: one connected to an on-chip ROM (SAR ROM), one connected to an on-chip RAM (SAR RAM), and one connected to an on-chip SRAM (L3 SRAM). Each memory controller has its own dedicated interface to the L3 interconnect.

15.1.6.1 SAR ROM

This on-chip ROM contains 4KB of memory and a linked list of descriptors used by sDMA during the restore context operation (when the device transitions from off to on mode).

The device-embedded SAR ROM has the following characteristics:

- 4-KB ROM
- 32-bit access per cycle
- Support for single- and burst-access transactions

15.1.6.2 SAR RAM

The on-chip SAR RAM contains 8K bytes and is mapped as 4 blocks with irregular region sizes. This memory content is preserved when the device goes into off mode (as long as the wake-up voltage domain remains supplied). It is used as context-saving memory to be written by software so that sDMA restores its saved content when the device transitions from off to on mode.

The device-embedded SAR RAM has the following characteristics:

- Support for single-access transactions
 - Operates at full L4-PER interconnect clock frequency
 - 32-bit access per cycle

15.1.6.3 L3 OCM_RAM

The on-chip L3 OCM_RAM contains 56KB of RAM, and partitioning is defined by the L3 firewall logic. The device-embedded L3 OCM_RAM has the following characteristics:

- Support for single and burst access transactions:
 - Operates at full L3 interconnect clock frequency
 - Fully pipelined, one 32-bit access per cycle
- Restricted access support

15.2 Dynamic Memory Manager

15.2.1 DMM Overview

This section describes the dynamic memory manager (DMM) and its Tiling and Isometric Lightweight Engine for Rotation (TILER) submodule.

The DMM is introduced in *Memory Overview* in [Chapter 15, Memory Subsystem](#).

On a purely functional perspective, the role of the DMM is to:

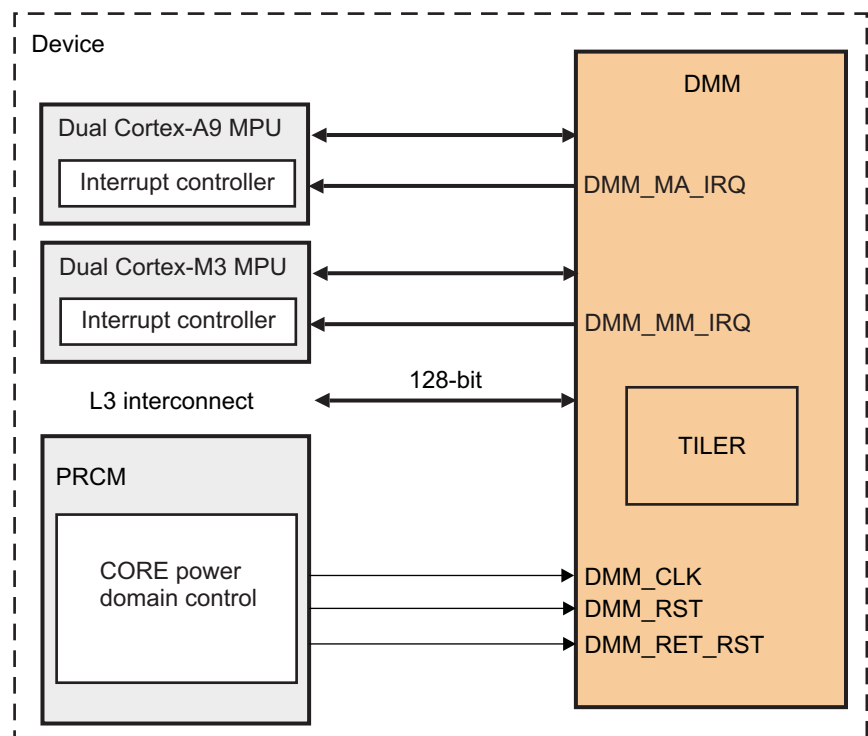

- Add initiator-based priority to any incoming requests
 - Perform to-and-from tiling conversions of "tiled" requests
 - Make on-the-fly basic itransforms such as quadrant rotations and mirroring
 - Optionally provide a low-latency page-based translation to handle memory fragmentation – MMU
 - Distribute the traffic on all attached memory controllers according to the interleaving configuration
- The TILER is also introduced in *Memory Overview* in [Chapter 15, Memory Subsystem](#).

It is a module aimed at:

- Primary handling efficiently 2-dimensional data mapped in tiles, such as video or graphics macroblocks
- Optionally managing the memory fragmentation and zero-copy physical frame buffers swapping through a page-grained translation
- Allowing optimized interlaced accesses on tiled frames
- Making distance-preserving transforms, such as 90°, 180°, or 270° rotations, with either a horizontal or vertical reflection
- Interleaving the memory accesses among the two memory controllers (also named EMIF, see [Section 15.3, EMIF Controller](#), for more information on it)

Figure 15-2 shows DMM and Tiler overview in the device.

Figure 15-2. DMM and Tiler Overview

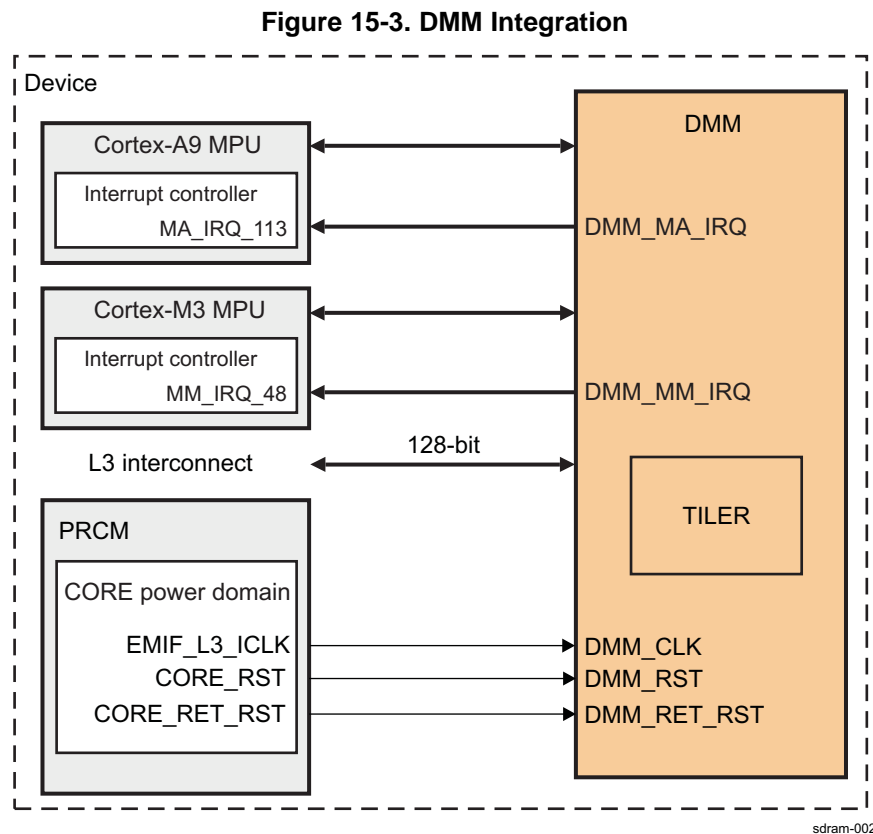

sdram-066

15.2.2 DMM Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- IDLE hardware handshake (the DMM only supports the smart-idle mode)
- No STANDBY hardware handshake
- No wake-up request
- No system direct memory access (sDMA) requests
- One interrupt line for interrupt request (IRQ)
- One functional clock

Figure 15-3 shows DMM integration.

NOTE: For more information about the IDLE hardware handshake, see [Chapter 3, Power, Reset, and Clock Management](#).

[Table 15-1](#) and [Table 15-3](#) summarize the DMM integration in the device.

Table 15-1. DMM Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-up Capability | Interconnect |
| DMM | PD_CORE | No | N/A |

15.2.3 DMM Functional Description

15.2.3.1 DMM Block Diagram

Figure 15-4 shows the DMM macro architecture. The DMM consists of six blocks:

- Two Tiling and Isometric Lightweight Engine for Rotation (TILER), having each their own interconnect slave port, for converting requests to-and-fro between the input virtual addressing mode and the output physical tiled addressing mode. Note that, the tiling conversions of requests, write data and responses is fully performed in the TILER blocks.
- Two Re-Ordering Buffer and Initiator Nodes (ROBIN), having each their own interconnect master port, to initiate requests to the SDRAM controller and allow tiled data, tiled response and split response reconstruction. The ROBIN block is only managing the re-ordering buffer and performing the data re-ordering due to the orientation.
- One Extra Low Latency Access (ELLA), having its own interconnect slave port, for providing lower latency accesses to the memory
- A Physical Address Translator (PAT) for managing the memory fragmentation
- A Priority Extension Generator (PEG) to generate priorities required by the SDRAM controller, note that these priorities are not used in the DMM
- A Local Interconnect and Synchronisation Agent (LISA) to synchronize all DMM subsystems and provide access to their configuration registers

Figure 15-4. DMM Block Diagram

sdram-003

CAUTION

It is the interconnect duty to ensure that virtually-addressed requests only target a TILER port and that only physically-addressed requests target an ELLA port.

15.2.3.2 DMM Clock Configuration

Table 15-5 describes the DMM clocks.

Table 15-5. DMM Clocks

| Signal | I/O ⁽¹⁾ | Description |
|---------|--------------------|--------------------------------|
| DMM_CLK | I | Functional and interface clock |

⁽¹⁾ I = Input; O = Output

The DMM is about SDRAM controller management and naturally sits in the MEMIF clock domain among the SDRAM controllers. The DMM is a fully synchronous module, which uses the clock and clock enable signals provided in the MEMIF clock domain for generating its interface and functional clocks.

To configure DMM_CLK control and settings, see Table 15-2.

15.2.3.3 DMM Power Management

DMM power is supplied by the CORE power domain, and DMM power management complies with system power-management guidelines.

Table 15-6 describes power-management features available for the DMM module.

Table 15-6. DMM Local Power Management Features

| Feature | Registers | Description |
|------------------------|------------------------------------------------------------|------------------------------------------|
| Clock Auto Gating | N/A | Feature not available |
| Slave Idle Modes | DMM_SYSCONFIG [3:2] SIDLEMODE bit field | Only Smart-idle wakeup mode is available |
| Clock Activity | N/A | Feature not available |
| Master Standby Modes | N/A | Feature not available |
| Global Wake-up Enable | N/A | Feature not available |
| Wake-up Sources Enable | N/A | Feature not available |

Some of the DMM module's registers are impacted by the Save And Restore (SAR) mechanism. For more information about SAR, see [Chapter 3, Power, Reset, and Clock Management](#).

15.2.3.4 DMM Interrupt Requests

Errors in PAT area refill registers are reported through the [DMM_PAT_STATUS_i](#)[15:10] ERROR bit field, as shown in [Table 15-7](#).

Table 15-7. DMM Hardware Status Features

| Feature | Type | Register | Description |
|-----------------|-----------|----------------------------------------------------------------|----------------------------------------------------|
| PAT error flags | Read only | DMM_PAT_STATUS_i [15:10] ERROR (i = 0 to 3) | Unexpected update of the PAT area refill registers |

[Table 15-8](#) lists the event flags, and their masks, that can cause module interrupts.

Table 15-8. Events

| Interrupt | Event Flag | Event Mask |
|---------------|----------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| ERR_LUT_MISS3 | DMM_PAT_IRQSTATUS [31] EVENT0 DMM_PAT_IRQSTATUS_RAW [31] EVENT0 | DMM_PAT_IRQENABLE_SET [31] EVENT0 DMM_PAT_IRQENABLE_CLR [31] EVENT0 |

15.2.3.5 DMM

15.2.3.5.1 DMM Concepts

The DMM introduces the concepts of dynamic mapping and DMM atomic units.

15.2.3.5.1.1 Dynamic Mapping

The DMM manages its internal memory space as an ordered set of up to four sections. [Figure 15-5](#) shows DMM sections and memory mapping.

Figure 15-5. DMM Sections and Memory Mapping

sdram_004

In the DMM, a section is:

- A segment of 16 MiB to 2 GiB, which is power-of-two in size and aligned to that size in the system map
- An area with a constant interleaving scheme - constant interleaving granularity on a constant set of SDRAM controller (EMIF) targets
- Given a priority equal to its index - the higher the index, the higher the priority.

NOTE: Whenever a request hits more than one DMM section, it follows the interleaving scheme of the section having the highest index.

The interleaving configuration of the DMM, its section-based dynamic memory mapping, is shown in the right hand side of [Figure 15-5](#). In this example, a request at the system address Addr will follow the interleaving scheme of section 3, although hitting sections 1, 2 and 3. Similarly, the DMM configuration given in this example prevents any request to use the interleaving scheme of section 0, since section 0 is fully masked by section 1 - which has a higher priority.

Each of the four sections is configured through a [DMM_LISA_MAP_i](#) register, where $i = 0$ to 3.

NOTE: The DMM and SDRAM controller registers ([Table 15-89](#) and EMIF registers, see [Section 15.3, EMIF Controller](#)) are actually declared in two extra static DMM sections of the highest priority so that they cannot be masked by any standard programmable DMM section.

NOTE: The DMM atomic size is:

- 1 kiB in non interleaved sections
 - equal to the interleaving granularity (128 bytes, 256 bytes or 512 bytes) in interleaved sections
-

15.2.3.5.1.2 Address Mapping

The address mapping inside the DMM is configurable through up to four sections. A DMM section description fits in a single register ([DMM_LISA_MAP_i](#)). Each section is defined based on:

- Its system address: the base address of the decoding range for the section.
- Its size: the encoding is the number of bits actually used in the upper 8-bits of the incoming system address.
- Its physical address: the base address of the memory range access in the external memory controller.
- Its address space: the address space used on the external (for the DMM) memory controller when hitting this section. See [Section 15.3.4.1.1, L3 Interface](#), for details.
- The target memory controller: a section may hit a single or pair of controllers.
- Its interleaving definition.

The address decoding is priority-based. In case of overlapping sections, only the highest-order one is hit. Register memory spaces have priority over regular memory sections. In case of four sections, the priority order is therefore:

1. Registers
2. DMM_LISA_MAP_3
3. DMM_LISA_MAP_2
4. DMM_LISA_MAP_1
5. DMM_LISA_MAP_0

All register-related addresses are reserved and fixed in the overall address mapping:

- DMM registers: 0x4E00_0000 to 0x4FFF_FFFF
- EMIF1 registers: 0x4C00_0000 to 0x4CFF_FFFF
- EMIF2 registers: 0x4D00_0000 to 0x4DFF_FFFF

There is no overlapping between register sections.

NOTE: Section decoding happens after PAT address translation in the case of TILER. In non-bypass mode, the system address considered for TILER accesses is actually the virtual address computed based on the PAT translation tables.

The [DMM_LISA_LOCK](#) register is used to lock the configuration once set. If written to one, the LOCK bit prevents further writes to all [DMM_LISA_MAP_i](#) registers. The LOCK itself cannot be written back to 0. A reset is required to reprogram the sections.

15.2.3.5.1.3 Address Translation

The physical address translation engine (PAT) of the DMM is composed of a 32-k entry physical address translation vector table and of one or two refill engines. The refill engine is a specialised DMA aimed at refilling the content of the physical address translation table.

The address translation mechanism is only available when the incoming request is hitting a page mode or tiled mode container, that is, when the incoming address is targeting the TILER or its aliased view in the system addressing space. Otherwise the physical address translation logic is bypassed so that the resulting physical address corresponds to the input address.

The PAT is supporting multiple address translation schemes, called views, which can be bound to one or more initiator through a view mapping mechanism.

15.2.3.5.1.3.1 PAT View Mappings

The PAT can have up to 16 groups of initiators sharing a set of 4 PAT views. The connection from an initiator to a PAT view is made through the [DMM_PAT_VIEW](#) register. Given that each PAT view index is coded on four bits, the [DMM_PAT_VIEW](#) register is a 64-bit register split in two 32-bit registers named [DMM_PAT_VIEW0](#) for the first eight PAT view indexes and [DMM_PAT_VIEW1](#) for the last eight PAT view indexes.

The PAT view index corresponding to the initiator having the value *i* as the four MSB of its L3 ConnID, will be using the view referenced in the entry *i* of the [DMM_PAT_VIEW](#). For instance the initiator 0xC4 will be using the 13th view index of the [DMM_PAT_VIEW](#) register, the 5th in the [DMM_PAT_VIEW1](#) register.

The PAT view index of the initiator i is found in the V_i field. The W_i field is aimed at writing the corresponding V_i . When writing to the `DMM_PAT_VIEW` registers, the only V_i view indexes that are updated are those having their corresponding W_i bit - and byte enable - set. The W_i bits are always read as 0. For instance, to set the PAT view indexes V_3 and V_7 to respectively 2 and 1, the `DMM_PAT_VIEW0` register shall be written with 5000 6000h.

15.2.3.5.1.3.2 PAT View Map Base Address

The PAT view map base address is defining the base address of all PAT translated addresses.

The bit 31 of all PAT translated address is set to `BASE_ADDR`. For instance if the `DMM_PAT_VIEW_MAP_BASE` register is set to 8000 0000h then all PAT translated addresses will have the bit 31 set to 1 so that the translated addresses were ranging from 8000 0000h to FFFF FFFFh. All reserved bits of this DMM PAT base address register are read to 0.

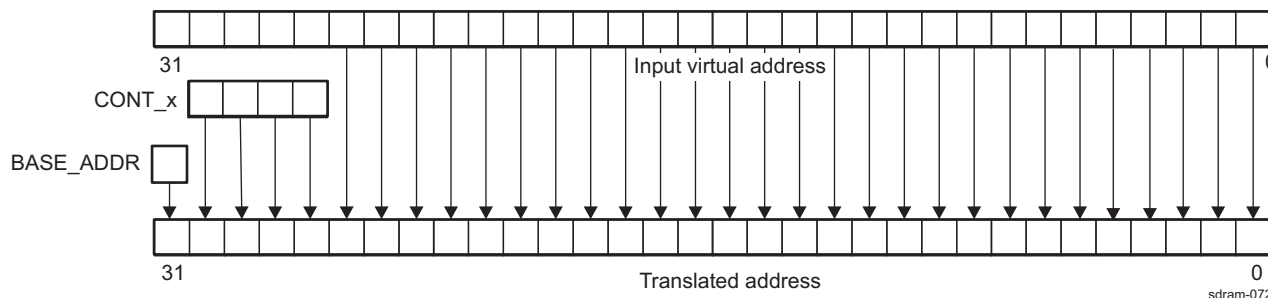

15.2.3.5.1.3.3 PAT Views

A PAT view is defining the kind of physical address translation to perform for each mode accesses (page, 8-bit, 16-bit and 32-bit). Each mode of each PAT view can be configured to either use a container-grained translation or a page-mode translation.

15.2.3.5.1.3.3.1 PAT Direct Access Translation

The container-grained translation is named the direct access. In this mode, the translation vector is directly given by the `CONT_x` field corresponding to the accessed mode. A page mode access is using the vector contained in the `DMM_PAT_VIEW_MAP_i[27:24]` `CONT_PAGE` field, a 32-bit mode access is using the vector contained in the `DMM_PAT_VIEW_MAP_i[19:16]` `CONT_32` field, a 16-bit mode access is using the vector contained in the `DMM_PAT_VIEW_MAP_i[11:8]` `CONT_16` field and an 8-bit mode access is using the vector contained in the `DMM_PAT_VIEW_MAP_i[3:0]` `CONT_8` field. See Figure 15-6.

Figure 15-6. PAT Direct Access Translation

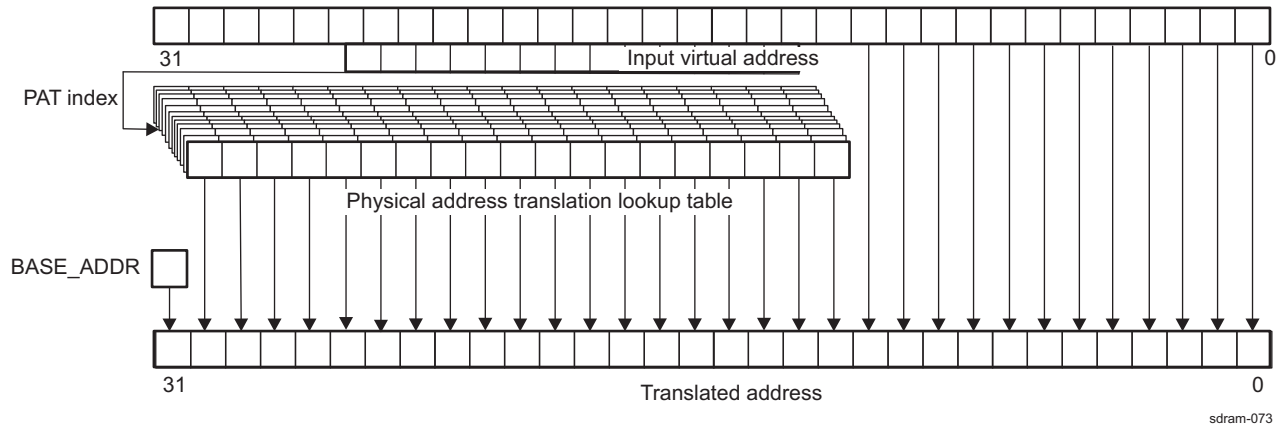

sdram-072

15.2.3.5.1.3.3.2 PAT Indirect Access Translation

The page-grained translation is named the indirect access. In this mode the translation vector is found in the internal 32-k entry physical address translation vector table at the index given by bits 12 to 26 of the input virtual address, and the `DMM_PAT_VIEW_MAP_i` `CONT_x` field is referencing the internal physical address translation table to use. Given that the DMM is only using one of such table, in this mode the `CONT_x` field shall be written as 0. See Figure 15-7.

Figure 15-7. PAT Indirect Access Translation

Each entry of the physical address translation lookup table is a 19-bit vector that will replace bits 12 to 30 of the input virtual address. The PAT index aimed at selecting the vector in the table consists of bits 12 to 26 of the input virtual address.

15.2.3.5.1.3.3.3 PAT View Configuration

There are four different views in a DMM each view has its own `DMM_PAT_VIEW_MAP_i` register aimed at defining the kind of address translation to perform.

The PAT view type of each mode is selected by the `ACCESS_x` field in the `DMM_PAT_VIEW_MAP_i` register, *i* being the index of the considered view. When this field is set to one then the indirect access scheme is used, otherwise the PAT is performing the address translation in a direct way with the corresponding `CONT_x` vector.

When configuring a mode in a view to use the indirect access, the corresponding `CONT_x` field shall be filled with 0.

15.2.3.5.1.3.3.4 PAT Address Translation Lookup Table

The PAT address translation lookup table has the same geometry as the DMM container. It has 128 lines of 256 entries of 19-bit each. See Figure 15-8.

Figure 15-8. Physical Address Translation Table

| | | | | | | | | | |
|-------------|-------------|-------------|-------------|-------------|---------------|---------------|---------------|---------------|---------------|
| $E_{0,0}$ | $E_{1,0}$ | $E_{2,0}$ | $E_{3,0}$ | $E_{4,0}$ | $E_{251,0}$ | $E_{252,0}$ | $E_{253,0}$ | $E_{254,0}$ | $E_{255,0}$ |
| $E_{0,1}$ | $E_{1,1}$ | $E_{2,1}$ | $E_{3,1}$ | $E_{4,1}$ | $E_{251,1}$ | $E_{252,1}$ | $E_{253,1}$ | $E_{254,1}$ | $E_{255,1}$ |
| $E_{0,2}$ | $E_{1,2}$ | $E_{2,2}$ | $E_{3,2}$ | $E_{4,2}$ | $E_{251,2}$ | $E_{252,2}$ | $E_{253,2}$ | $E_{254,2}$ | $E_{255,2}$ |
| $E_{0,125}$ | $E_{1,125}$ | $E_{2,125}$ | $E_{3,125}$ | $E_{4,125}$ | $E_{251,125}$ | $E_{252,125}$ | $E_{253,125}$ | $E_{254,125}$ | $E_{255,125}$ |
| $E_{0,126}$ | $E_{1,126}$ | $E_{2,126}$ | $E_{3,126}$ | $E_{4,126}$ | $E_{251,126}$ | $E_{252,126}$ | $E_{253,126}$ | $E_{254,126}$ | $E_{255,126}$ |
| $E_{0,127}$ | $E_{1,127}$ | $E_{2,127}$ | $E_{3,127}$ | $E_{4,127}$ | $E_{251,127}$ | $E_{252,127}$ | $E_{253,127}$ | $E_{254,127}$ | $E_{255,127}$ |

| | |
|-----------|-----------------|
| $E_{x,y}$ | 4-KB page entry |
|-----------|-----------------|

sdr-am-074

Each entry of the PAT address corresponds to the page in the DMM container that has the same location. The entry (74, 42) in the table corresponds to the page (74, 42) in any DMM container.

15.2.3.5.1.3.3.5 **Direct Access to the PAT Physical Address Translation Table Vectors**

The PAT physical address translation table is typically refilled with specialised DMA called refill engines. Still some direct read and write access to the content of this table is granted when disabling the use of one or the other refill engine by writing a 1 in the MODE_i field of the [DMM_PAT_CONFIG](#) corresponding to the refill engine *i* to disable.

In this mode, often called the debug mode, the data read in or written to the [DMM_PAT_DATA_i](#) register corresponds to the vector contained in the physical address translation table which index is found in the X0 and Y0 fields of the [DMM_PAT_AREA_i](#) register.

15.2.3.5.1.3.3.6 **Automatic Refill Through the Refill Engines**

See [Section 15.2.4.1](#), *PAT Use Cases*.

15.2.3.5.2 **DMM Transaction Flows**

15.2.3.5.2.1 **Non-Tiled Transaction Flow**

Each non-tiled interconnect transaction reaching the DMM, either on a TILER port or on an extra low-latency access port (ELLA), is subject to the same processing.

The TILER and ELLA blocks consider separated request, data and response paths. An overview of each path is given below, and more detailed information is given in [Section 15.2.3.5.3](#), *DMM Internal Macro-Architecture*.

On the request path, the flow consists of:

- Allocating a TILER / ELLA response context to timely generate the appropriate responses
- Splitting 2D requests in a collection of 1D requests - TILER ports only
- Splitting requests at DMM unit boundaries - the split granularity being provided by LISA mapping registers
- Allocating an available buffer in the appropriate ROBIN, for both read and write requests
- In case of a write request, allocating and updating a TILER / ELLA write context to subsequently direct the incoming write data into the relevant re-ordering buffer
- Generating the initiator-indexed priority extension - via the PEG block

On the write data path, the flow consists of forwarding incoming data to the relevant re-ordering buffer in accordance with the corresponding TILER / ELLA write context.

On the response path, responses are returned as soon as:

- At least one response have entered each related buffers, in case of read requests
- All related responses have returned from the SDRAM controller, in case of write requests
- No other previous pending response exists with the same tag

15.2.3.5.2.2 **Tiled Transaction Flow**

Similarly each tiled interconnect transaction reaching the DMM is subject to the same processing.

The TILER blocks consider separated request, data and response paths. An overview of each path is given below, more detailed information being given in [Section 15.2.3.5.3](#), *DMM Internal Macro-Architecture*.

On the request path, the processing phase consists of:

- Decoding the address to qualify whether the request targets the TILER or the memory directly
- Transforming TILER-specific requests to their natural representation - address, width and height are modified accordingly

On the request path, the generation phase consists of:

- Allocating a TILER response context to timely generate the appropriate responses
- Splitting malformed - request's stride is different from the container stride and from the double of this container stride - tiled 2D requests in a collection of 1D requests
- Splitting tiled requests at tile boundaries
- Performing the page-based address translation - via the PAT block
- Allocating an available buffer in the appropriate ROBIN, for both read and write requests
- In case of a write request, allocating and updating a TILER write context to subsequently direct the incoming write data into the relevant re-ordering buffer
- Generating the initiator-indexed priority extension - via the PEG block

On the data path, any incoming data is transformed in accordance with the corresponding TILER write context and sent to the appropriate re-ordering buffer.

On the response path, responses are returned as soon as:

- A minimal number of responses have entered the corresponding buffers, in case of read requests
- All related responses have returned from the SDRAM controllers, in case of write requests
- No other previous pending response exists with the same tag

15.2.3.5.3 DMM Internal Macro-Architecture

This sub-section describes the DMM internal macro-architecture, specifically:

- Input request decoding,
- Physical address translation and synchronized translation table reloading,
- Output request and response generation,
- Memory mapping in the system addressing space - including interleaving,
- Tag management,
- Priority handling,
- Contexts,
- Maximum allowed burst size,
- Reconstruction buffer dimensioning.

15.2.3.5.3.1 ELLA Description

The Extra Low Latency Access (ELLA) block is basically a TILER block which has been simplified to reduce the latency. In this respect, the ELLA block:

- Is limited to 1D bursts only
- Is not capable of performing tiling conversions
- Does not interact with the PAT block

The ELLA block main role is to split incoming requests at DMM atomic unit boundaries to ensure that requests sent to the SDRAM controller fit in a single SDRAM page. More precisely, the ELLA block is responsible for:

- Allocating an internal response context to timely generate the appropriate responses
- Splitting requests at DMM atomic section boundaries
- Requesting buffer allocation in the appropriate ROBIN
- In case of a write request, allocating and updating an internal write context to subsequently direct the incoming write data into the relevant re-ordering buffer.

15.2.3.5.3.2 LISA Description

The Local Interconnect and Synchronisation Agent (LISA) is a full crossbar aimed at setting priorities, managing tags and memory mapping.

The interconnect routes:

- TILER requests on the ROBIN initiator nodes
- TILER write data on the ROBIN write buffers
- ROBIN read data to the relevant TILER initiators.

The LISA block registers are [DMM_LISA_MAP_i](#) (i = 0 to 3) and [DMM_LISA_LOCK](#).

The priority is given to the low-latency port (ELLA). When 2 ROBIN are in use, it interleaves the two ports at a programmable boundary from 128 Bytes or more (configurable with [DMM_LISA_MAP_i\[19:18\]](#) SDRG_INTL bit field).

15.2.3.5.3.3 PAT Description

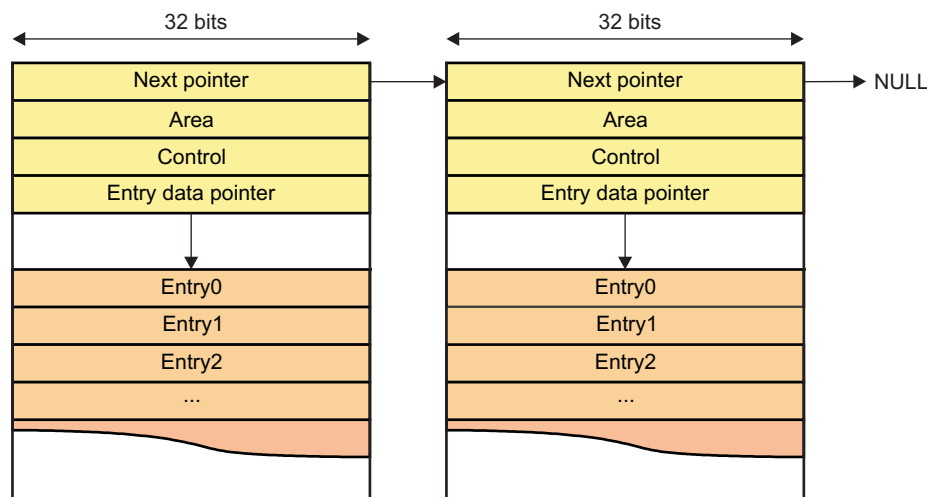

The Physical Address Translator (PAT) block is responsible for mapping physical pages to each TILER container page. The internal address translation memories used in the PAT block are designed with retention flip-flops. It consists of:

- a memory-based LUT which has the same geometry as the container pages
- a refill engine for modifying entries in a given area of the internal LUT

A PAT descriptor is a singly-linked list node as shown [Figure 15-9](#), containing:

- a description of the LUT area to reload
- a description of how to reload the defined LUT area
- a pointer to the location where the corresponding LUT entries are stored

Figure 15-9. PAT Descriptors

PAT descriptors are chained and processed until a NULL pointer is encountered. The PAT bank allocation scheme allows the update of 4 consecutive entries of a line in a single cycle whatever the refilling orientation.

The PAT descriptor structure directly maps the [DMM_PAT_DESCR_i](#), [DMM_PAT_AREA_i](#), [DMM_PAT_CTRL_i](#) and [DMM_PAT_DATA_i](#) registers (i = 0 to 3).

The PAT refill engine can be started by:

- filling manually all the necessary registers: the [DMM_PAT_AREA_i](#) register with the (x0, y0) (x1, y1) area definition, the [DMM_PAT_DATA_i](#) with the physical address of the corresponding area entry table, the [DMM_PAT_CTRL_i\[6:4\]](#) DIRECTION with the relevant (S, Y, X) direction of the area refill and the [DMM_PAT_CTRL_i\[0\]](#) START with a 1.
- writing the physical address of a memory-mapped PAT descriptor in the [DMM_PAT_DESCR_i](#) which will update: the [DMM_PAT_AREA_i](#) with the area value of the descriptor, the [DMM_PAT_DATA_i](#) with the data value of the descriptor, the [DMM_PAT_CTRL_i](#) with the ctrl value of the descriptor and the

[DMM_PAT_DESCR_i](#) with the next value of the descriptor.

- In any case the data part of the PAT refill only starts when [DMM_PAT_CTRL_i\[0\]](#) START is asserted. The [DMM_PAT_STATUS_i](#) register can be used to see if the process has completed without errors.

15.2.3.5.3.4 PEG Description

The priority extension generator (PEG) is a dynamic software-programmable initiator-ConnID-indexed table of priorities. Its role is to change on the fly the priority of an initiator. The mapping of each initiator to the table (split into eight registers) is based on its 6-MSB group ConnID (see [Table 28-20, ConnID Mapping \(Debug View\)](#), in [Chapter 28, On-Chip Debug Support](#)).

When an interconnect request enters the DMM, its priority is extracted from the PEG lookup table and set in its MReqInfo field.

The 64 priority entries are software-programmable with eight [DMM_PEG_PRIO](#) registers ([DMM_PEG_PRIO_k](#)).

Each of these eight registers is split in eight 4-bit fields, each field mapping an entry of the lookup table with:

- The 3-bit priority coded on the 3 least-significant bits (LSBs): P_x field. A priority of 0 defines the highest priority and a priority of 7 defines the lowest priority. At reset, all priorities are set to 4. The priority of a request with ConnID equal to y is written in the (8.k + x) P field, where k is the number of the priority register (k = 0 to 7) and x is the number of the P field in the corresponding register (x = 0 to 7). For example, if the ConnID is 0x16, its priority is written in the third priority register (k = 2), in the P6 bit field ([26:24]), because x = 6.

Table 15-9. ConnIDs Vs PEG Priority Register Fields

| RegisterField | P0 | P1 | P2 | P3 | P4 | P5 | P6 | P7 |
|----------------|----------|----------|----------|----------|----------|----------|----------|----------|
| DMM_PEG_PRIO_0 | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| DMM_PEG_PRIO_1 | 8 | 9 | 10(0xA) | 11(0xB) | 12(0xC) | 13(0xD) | 14(0xE) | 15(0xF) |
| DMM_PEG_PRIO_2 | 16(0x10) | 17(0x11) | 18(0x12) | 19(0x13) | 20(0x14) | 21(0x15) | 22(0x16) | 23(0x17) |
| DMM_PEG_PRIO_3 | 24(0x18) | 25(0x19) | 26(0x1A) | 27(0x1B) | 28(0x1C) | 29(0x1D) | 30(0x1E) | 31(0x1F) |
| DMM_PEG_PRIO_4 | 32(0x20) | 33(0x21) | 34(0x22) | 35(0x23) | 36(0x24) | 37(0x25) | 38(0x26) | 39(0x27) |
| DMM_PEG_PRIO_5 | 40(0x28) | 41(0x29) | 42(0x2A) | 43(0x2B) | 44(0x2C) | 45(0x2D) | 46(0x2E) | 47(0x2F) |
| DMM_PEG_PRIO_6 | 48(0x30) | 49(0x31) | 50(0x32) | 51(0x33) | 52(0x34) | 53(0x35) | 54(0x36) | 55(0x37) |
| DMM_PEG_PRIO_7 | 56(0x38) | 57(0x39) | 58(0x3A) | 59(0x3B) | 60(0x3C) | 61(0x3D) | 62(0x3E) | 63(0x3F) |

- A \overline{W} field-specific active-low local write enable bit, always read as 0, on the most-significant bit (MSB). The role of the \overline{W} bit is to allow the modification of a single entry without requiring a read-modify-write sequence. As its \overline{W} bits are always read as 0, writing back the modified register updates all priority fields of the register.

Although this priority information is generated prior to entering the LISA block, it is not used internally in the local interconnect arbitration, but forwarded to the EMIF controller as an MReqInfo, where it indicates the command priority.

It is also possible to give a priority for the internal PAT engine thanks to the [DMM_PEG_PRIO_PAT](#) register.

15.2.3.5.3.5 ROBIN Description

The reordering buffer and initiator node (ROBIN) is a block aimed at providing some working buffering for:

- Converting data and responses to-and-fro between raster and tiled organizations and a master port to connect to the SDRAM controller.

The ROBIN block does:

- Request Forwarding
- Write data and Response buffering
- Keeps write data ordering

- Intra-word tiling and orientation transforms
- Tag handling

15.2.3.5.3.6 TILER Description

The tiling and isometric lightweight engine for rotation (TILER) main functionality is the request conversion due to the tiling. The TILER block is then responsible for:

- Decoding the address to qualify whether the request targets the TILER or the memory directly
- Converting TILER-specific requests to their natural representation – address, width and height are modified accordingly
- Allocating an internal response context to timely generate the appropriate responses
- Splitting tiled requests at tile boundaries and not tiled requests at DMM atomic section boundaries
- Requesting the page-based address translation
- Requesting buffer allocation in the appropriate ROBIN
- In case of a write request, allocating and updating an internal write context to subsequently direct the incoming write data into the relevant reordering buffer.

The interdependent tiling and isometric transform concepts introduced in the TILER are fully described in the following section.

15.2.3.6 TILER

15.2.3.6.1 TILER Concepts

This section describes all concepts behind the TILER transforms, through a top-down approach starting from the main object container.

15.2.3.6.1.1 TILER Rationale

This section is a synthesis of all TILER concepts, giving one rule per TILER structure level.

[Figure 15-10](#) shows the TILER address space structure for tiled modes.

Figure 15-10. TILER Address Space Structure for Tiled Modes

sdram-005_public

15.2.3.6.1.1.1 The TILER is a 4-GiB Virtual Address Space Composed of Eight Views

There is one view for each of the eight possible way of scanning a frame-buffer:

1. From left to right then from top to bottom

2. From right to left then from top to bottom
3. From left to right then from bottom to top
4. From right to left then from bottom to top
5. From top to bottom then from left to right
6. From top to bottom then from right to left
7. From bottom to top then from left to right
8. From bottom to top then from right to left

15.2.3.6.1.1.2 A View is a 512-MiB Virtual Address Space Composed of Four Containers

There is one container per element size to allow correct access patterns in any of the eight possible orientations. The container is the entity where all objects of a given element type are allocated.

The element is the entity of maximum size - 8 bits, 16 bits, 32 bits or page-sized - which is invariant in any orientation.

15.2.3.6.1.1.3 A Container is a 128-MiB Virtual Address Space

A container is composed of an array of 128 lines of 256 pages of 4 kiB each.

The page defines the granularity of physical memory allocation through a physical address translation unit - MMU.

15.2.3.6.1.1.4 A Page is a 4-kiB Virtual Address Space

A page is composed of two lines. Each line consists of two tiles.

15.2.3.6.1.1.5 A Tile is a 1-kiB Address Space

The tile is designed to offer bi-dimensional data locality in a single SDRAM page. In this respect, it has been sized to 1 kiB, that is, to the size of the smallest SDRAM page.

15.2.3.6.1.2 TILER Modes

The TILER is supporting three major modes - bypass, page and tiled - each having a specific output request generation.

15.2.3.6.1.2.1 Bypass Mode

As stated in its name, this mode is transparent at the TILER perspective. Still, at the DMM perspective,

- 2D block bursts are broken down on a line-basis in a set of incremental bursts
- Incremental bursts - including those issued by a 2D block burst breakdown - are split at the DMM atomic unit of the section hit by the burst at:
 - at the interleaving granularity of the section - 128 byte, 256 byte or 512 byte - in interleaved sections
 - at 1-kiB boundary in non-interleaved sections

15.2.3.6.1.2.2 Page Mode

The purpose of this mode is to use the DMM address translation mechanism for non-tiled accesses. In this respect it is similar to the bypass mode,

- 2D block bursts are broken down on a line-basis in a set of incremental bursts
- Incremental bursts - including those issued by a 2D block burst breakdown - are split at:
 - the interleaving granularity of the section - 128 byte, 256 byte or 512 byte - in interleaved sections
 - 1-kiB boundary in non-interleaved sections

15.2.3.6.1.2.3 Tiled Mode

The tiled mode has two major breakdown algorithms,

- One for well formed 2D block requests - conforming to the orientation, mode and stride given in Table 15-10
- One for 1D incremental requests and ill-formed 2D block requests.

Table 15-10. Well Formed Tiled Mode 2D Block Requests

| Orientation | | | Mode | | Stride (bytes) | Description |
|-------------|---|---|------|----|----------------|-----------------------------------------------------------|
| S | Y | X | M1 | M0 | | |
| 0 | x | x | 0 | 0 | 16384 | Plain access to an 8-bit progressive frame in 0° or 180° |
| | | | | | 32768 | Field access to an 8-bit interlaced frame 0° or 180° |
| | | | 0 | 1 | 32768 | Plain access to a 16-bit progressive frame in 0° or 180° |
| | | | | | 65536 | Field access to a 16-bit interlaced frame 0° or 180° |
| | | | 1 | 0 | 32768 | Plain access to a 32-bit progressive frame in 0° or 180° |
| | | | | | 65536 | Field access to a 32-bit interlaced frame 0° or 180° |
| 1 | x | x | 0 | 0 | 8192 | Plain access to an 8-bit progressive frame in 90° or 270° |
| | | | | | 16384 | Field access to an 8-bit interlaced frame 90° or 270° |
| | | | 0 | 1 | 8192 | Plain access to a 16-bit progressive frame in 90° or 270° |
| | | | | | 16384 | Field access to a 16-bit interlaced frame 90° or 270° |
| | | | 1 | 0 | 16384 | Plain access to a 32-bit progressive frame in 90° or 270° |
| | | | | | 32768 | Field access to a 32-bit interlaced frame 90° or 270° |

Similarly to the bypass and page modes, ill formed 2D block requests are broken down on a line basis in a set of incremental bursts. In tiled mode however, these incremental virtual bursts do not translate to 1D physical burst requests.

15.2.3.6.1.3 Object Container Definition

The object container is the unique addressable entry point of the TILER. It is a 128-MiB virtual address space, where all objects of a same kind - and orientation - are allocated.

Four main types of containers are present in the TILER, each one being referred by a mode:

- A 8-bit element mode, for efficiently accessing bi-dimensional arrays of 8-bit data
- A 16-bit element mode, for efficiently accessing bi-dimensional arrays of 16-bit data
- A 32-bit element mode, for efficiently accessing bi-dimensional arrays of 32-bit data
- A page mode, for efficient 1D accesses

Figure 15-11 shows the TILER object containers and views

Figure 15-11. TILER Object Containers and Views

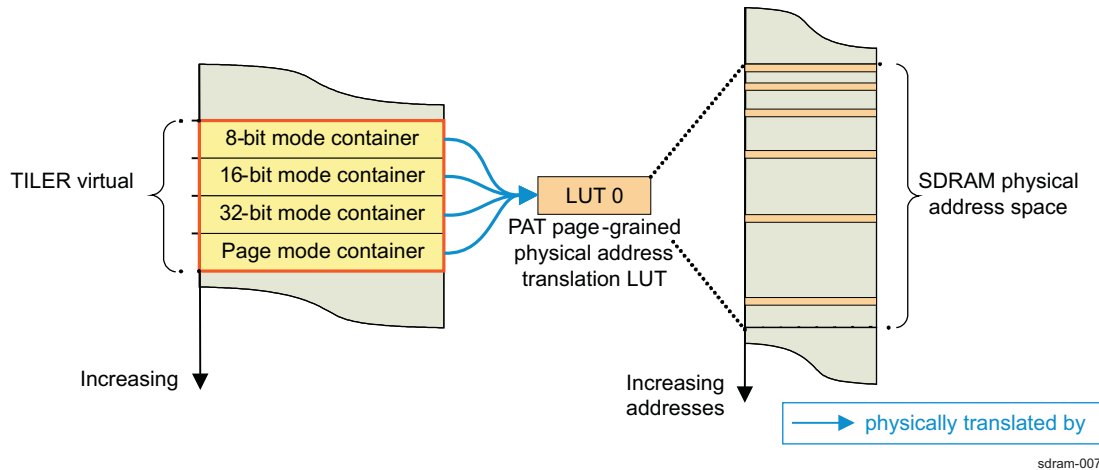

The 512-MiB virtual address space composed of four 128-MiB object containers of different modes is called a view. Given that 8 orientations are available per mode, the TILER is actually managing 32 kinds of containers.

The physical memory footprint of a 512-MiB TILER view is directly subject to the nature of the physical address translator unit - PAT.

A unique physical address translation table - LUT (Look Up Table) is instantiated in the DMM. This table is shared by all TILER modes. Hence, each of the four modes can not be given their own private page-grained physical address translation table - LUT. A maximum of 128 MiB of objects among all TILER modes can be managed as illustrated in [Figure 15-12](#).

Figure 15-12. TILER Memory Footprint with PAT and Shared Physical Address Translation LUT

If the four modes have all their own separated virtual 128-MiB object containers, these containers are all mapped to the same piecewise 128-MiB physical address space, and are then not physically separated. Consequently, a memory-related system constraints is that no more than 128-MiB of objects can be available simultaneously in a TILER view.

NOTE: It is a software duty to ensure that any object allocated in a mode do not physically overlap with any other object, even in another mode.

15.2.3.6.1.4 Page Definition

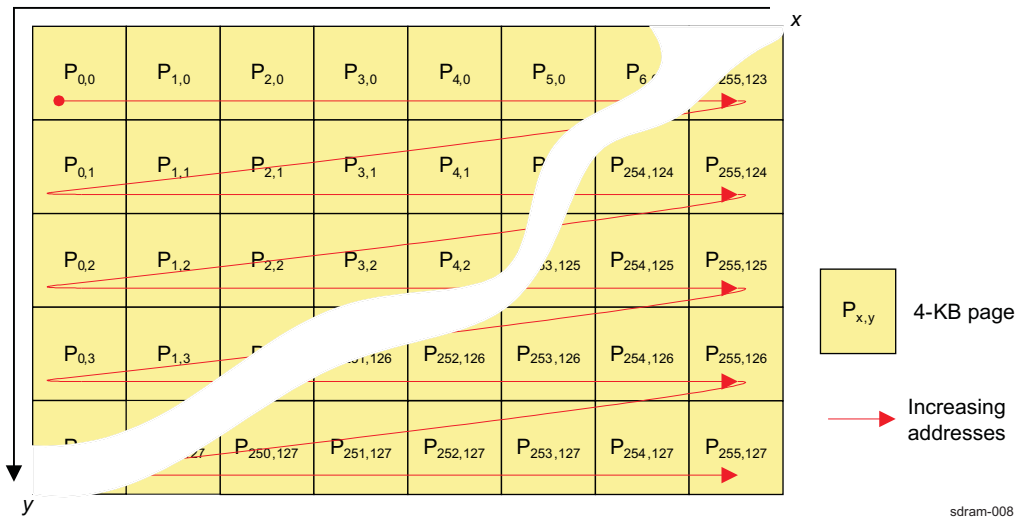

A TILER page defines the granularity of object allocation in virtual TILER containers.

Given that the sub-page structure is mode specific, the page is the smallest granularity common to all modes, making it the granularity to consider in the TILER resource manager for object allocation.

15.2.3.6.1.4.1 Container Geometry with 4-kiB Pages

As pages size is 4-kiB, any 128-MiB object container is a set of 32768 pages, organized in an array of 256 columns and 128 rows, as shown in [Figure 15-13](#).

Figure 15-13. Object Container Geometry with 4-kiB Pages

This array of pages is mapped to the system address space as shown in Figure 15-14.

Figure 15-14. TILER Page Mapping when Using 4-kiB Pages

In any 128-MiB object container, the 4-kiB page $P_{x,y}$ at column x ($0 \leq x < 256$) and row y ($0 \leq y < 128$), is found at an offset of $4096 \cdot (x + 256 \cdot y)$ bytes from the base address of the related object container.

Similarly, the page $P_{x,y}$ at column x ($0 \leq x < 256$) and row y ($0 \leq y < 128$), is translated by the LUT entry $E_{x+256 \cdot y}$ found at the index $x + 256 \cdot y$.

15.2.3.6.1.4.2 Container Geometry and Page Mapping Summary

The TILER has a page size of 4096 bytes. The page $P_{x,y}$:

- has $\max_x = 256$ and $\max_y = 128$.
- is found at an offset of: $4096 \cdot (x + \max_x \cdot y)$ bytes from the base address of the related object container
- is translated by the entry found at the index $(x + \max_x \cdot y)$ of the LUT table

15.2.3.6.1.5 Orientation

This section describes the eight on-the-fly orientation-related isometric transforms, corresponding to all available changes of orthonormal basis in the TILER container bi-dimensional space.

Figure 15-15 shows isometric transforms in the TILER container

Figure 15-15. Isometric Transforms in the TILER Container

sdram-010

Mathematically speaking, all these transforms correspond to the composition of a 0° , 90° , 180° , or 270° rotation with an optional reflection. The nature of this orientation is based on the three following binary parameters:

- X to change the direction of the x axis of the TILER container;
- Y to change the direction of the y axis of the TILER container;
- S to swap the modified x and y axis.

From now on, and in the rest of this document, the term orientation refers to any composition of a "quadrant" rotation with an optional horizontal - flip-flop - or vertical mirroring.

15.2.3.6.1.6 Tile Definition

A tile is a subdivision of a page, aimed at:

- Representing a 2D block to better balance the accesses in both directions
- Ensuring that any "tiled" access that fits within a tile is made atomic in the SDRAM controller, and fits in a single SDRAM memory page
- Minimising the number of SDRAM page openings per 2D block transfer

The tile is defined as a 1-kB 2D block, and a 4-kB page as an array of 2 lines of 2 tiles each.

When the considered page is in an interleaved DMM section, it is necessary that:

- the DMM memory interleaving size of tiled accesses is set to 1 kB - a tile size - so that any tiled request that fits within a tile, fits in a single SDRAM memory page
- any request that spans over 2 or 4 tiles, is distributed on a maximum number of SDRAM memory controllers

15.2.3.6.1.7 TILER Virtual Addressing

The TILER can be virtually accessed in four different modes, namely 8-bit, 16-bit, 32-bit and page modes. Each mode defines the element granularity to apply isometric transforms, as summarized in Table 15-11.

Table 15-11. Coding and Description of TILER Modes

| Mode | Name | Granularity (element size) |
|------|-------------------|----------------------------|
| 0 | 8-bit tiled mode | 8 bits |
| 1 | 16-bit tiled mode | 16 bits |
| 2 | 32-bit tiled mode | 32 bits |
| 3 | Page mode | 4096 bytes |

For instance, making a vertical mirroring of a 16-byte horizontal line containing the word 000102030405060708090A0B0C0D0E0Fh, leads to:

- 0F0E0D0C0B0A09080706050403020100h in 8-bit tiled mode
- 0E0F0C0D0A0B08090607040502030001h in 16-bit tiled mode
- 0C0D0E0F08090A0B0405060700010203h in 32-bit tiled mode
- 000102030405060708090A0B0C0D0E0Fh in page mode - unchanged as the element granularity is 4 KB.

Besides, as each of the eight orientations is available for any of the four modes, this gives 32 TILER addressing possibilities, as summarized in [Table 15-12](#).

Table 15-12. Coding and Description of TILER Orientations

| S | Y | X | Description | Alternate description |
|---|---|---|---------------------------------|----------------------------------|
| 0 | 0 | 0 | 0° view | Natural view |
| 0 | 0 | 1 | 0° view with vertical mirror | 180° view with horizontal mirror |
| 0 | 1 | 0 | 0° view with horizontal mirror | 180° view with vertical mirror |
| 0 | 1 | 1 | 180° view | |
| 1 | 0 | 0 | 90° view with vertical mirror | 270° view with horizontal mirror |
| 1 | 0 | 1 | 270° view | |
| 1 | 1 | 0 | 90° view | |
| 1 | 1 | 1 | 90° view with horizontal mirror | 270° view with vertical mirror |

15.2.3.6.1.7.1 Page Mode Virtual Addressing and Characteristics

When used in page mode, the 128-MiB TILER space is seen as an orientation-specific sequence of 32768 pages of 4 kiB each. The access sequence inside a page is left unchanged.

Therefore, in page mode, the TILER is accessed similarly to any 128-MiB memory, with a 27-bit byte-based address.

NOTE: From now on the address is noted "a".

Figure 15-16. Page Mode Virtual Addressing

s dram-027

15.2.3.6.1.7.2 Tiled Mode Virtual Addressing and Characteristics

When used in tiled mode, the 128-MiB TILER space is seen as a giant frame-buffer - the container. The addressing and characteristics of this giant frame-buffer depends on:

- The tiled mode, which defines the considered atomic element size.
- The orientation, which potentially swaps its x and y axis - and hence the container geometry.

[Table 15-13](#) summarizes tiled mode container characteristics.

Table 15-13. Tiled Mode Container Characteristics

| Orientation S | Υ | \bar{X} | Element size (bits) | Width (elements) | Height (elements) | Stride (bytes) | |
|------------------|------------|-----------|------------------------|---------------------|----------------------|----------------|------------|
| | | | | | | Progressive | Interlaced |
| 0 | x | x | 8 | 16384 | 8192 | 16384 | 32768 |
| | | | 16 | 16384 | 4096 | 32768 | 65536 |
| | | | 32 | 8192 | 4096 | 32768 | 65536 |
| 1 | x | x | 8 | 8192 | 16384 | 8192 | 16384 |
| | | | 16 | 4096 | 16384 | 8192 | 16384 |
| | | | 32 | 4096 | 8192 | 16384 | 32768 |

As a result, the coordinate (x_0, y_0) of a pixel in an oriented view is translated in a virtual address as shown in [Figure 15-17](#) and [Figure 15-18](#).

Figure 15-17. Tiled Mode Addressing in 0° or 180° Orientations (S=0)**Figure 15-18. Tiled Mode Addressing in 90° or 270° Orientations (S=1)**

15.2.3.6.1.7.3 Element Ordering in the TILER Container

This section highlights how elements - 8-bit data, 16-bit data, 32-bit data or 4-kB page - are ordered in the container. In other words, this section highlights how the path of incrementing virtual addresses is mapped in the container.

It is interesting to note that whatever the mode, and hence the element size, the sequence for ordering the elements in their related container is strictly similar and only depends on the related orientation. In other words:

- Mode is about element granularity
- Orientation is about change of orthonormal basis for ordering the elements in the mode-specific container.

A corollary to the previous statements is that in a given mode the internal structure of an element is unchanged whatever the orientation. In page mode for instance, the offset of a word inside a page is invariant by orientation; the content of a page is always accessed in the same manner.

In the next sections, the natural container orthonormal basis is referenced as:

$$(\vec{x}_N, \vec{y}_N)$$

sdram-030

and the oriented orthonormal basis as:

$$(\vec{x}_O, \vec{y}_O)$$

sdram-031

15.2.3.6.1.7.3.1 Natural View or 0° View (orientation 0)

This orientation defined by $S=0$, $\bar{Y}=0$ and $\bar{X}=0$ and means that the operated change of basis is:

$$\begin{cases} \bar{x}_O = \bar{x}_N \\ \bar{y}_O = \bar{y}_N \end{cases}$$

sdram-032

In any TILER mode, the elements are then ordered from left-to-right and then from top-to-bottom in their container, as shown in Figure 15-19 and Figure 15-20.

Figure 15-19. Tiled Mode Ordering of Elements in Natural View

Figure 15-20. Page Mode Ordering of Elements in Natural View

15.2.3.6.1.7.3.2 0° View with Vertical Mirror or 180° View with Horizontal Mirror (Orientation 1)

This orientation defined by $S=0$, $\bar{Y}=0$ and $\bar{X}=1$ and means that the operated change of basis is:

$$\begin{cases} \bar{x}_O = -\bar{x}_N \\ \bar{y}_O = \bar{y}_N \end{cases}$$

sdram-035

In any TILER mode, the elements are then ordered from right-to-left and then from top-to-bottom in their container, as shown in Figure 15-21 and Figure 15-22.

Figure 15-21. Tiled Mode Ordering of Elements in 0° View with Vertical Mirror

Figure 15-22. Page Mode Ordering of Elements in 0° View with Vertical Mirror

15.2.3.6.1.7.3.3 0° View with Horizontal Mirror or 180° View with Vertical Mirror (Orientation 2)

This orientation defined by $S=0$, $\bar{Y}=1$ and $\bar{X}=0$ and means that the operated change of basis is:

$$\begin{cases} \bar{x}_O = \bar{x}_N \\ \bar{y}_O = -\bar{y}_N \end{cases}$$

sdram-038

In any TILER mode, the elements are then ordered from left-to-right and then from bottom-to-top in their container, as shown in Figure 15-23 and Figure 15-24.

Figure 15-23. Tiled Mode Ordering of Elements in 0° View with Horizontal Mirror

Figure 15-24. Page Mode Ordering of Elements in 0° View with Horizontal Mirror

15.2.3.6.1.7.3.4 180° View (Orientation 3)

This orientation defined by $S=0$, $\bar{Y}=1$ and $\bar{X}=1$ and means that the operated change of basis is:

$$\begin{cases} \bar{x}_O = -\bar{x}_N \\ \bar{y}_O = -\bar{y}_N \end{cases}$$

sdram-041

In any TILER mode, the elements are then ordered from right-to-left and then from bottom-to-top in their container, as shown in Figure 15-25 and Figure 15-26.

Figure 15-25. Tiled Mode Ordering of Elements in 180° View

Figure 15-34. Page Mode Ordering of Elements in 90° View with Horizontal Mirror

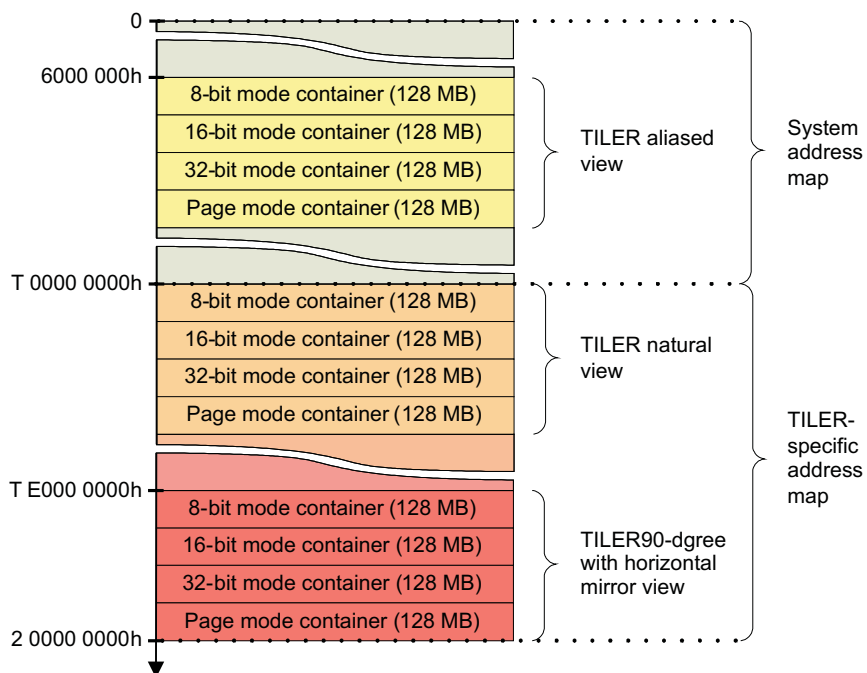

15.2.3.6.2 TILER Macro-Architecture

The TILER requires a 4-GiB addressing space to map its 128-MiB physical container in 4 modes and 8 orientations. As its addressing space fills along the 4-GiB global system address map, the TILER addressing space cannot enter as-is in the system address map. Besides, putting in place a register-based mechanism per initiator to specify the orientation of the following accesses and then reduce the TILER addressing space to a single 512-MiB view is not an option, given that most of the bandwidth-hungry initiators require simultaneous accesses to the TILER container in different views.

As a result 32 bits are not enough to address all these requests, since the TILER port must convey virtually-addressed requests to the "oriented" TILER containers, but also physically-addressed requests to the attached SDRAM controllers. A 33rd address bit is necessary to distinguish the two separated address map as illustrated in Figure 15-35.

Figure 15-35. TILER Port Address Map

sdram-056

Still, having separated system and TILER-specific address maps is not sufficient. In a system, many existing and external IP blocks still rely on a 32-bit address, and would then be limited to one or the other 4-GiB addressing space. To overcome this limitation, one 512-MiB view is aliased in the system address map as described in table and fig.

Table 15-14. TILER Aliased View in the L3 Interconnect Mapping

| Start address (hex) | End address (hex) | Size |
|---------------------|-------------------|-------|
| 0x6000_0000 | 0x7FFF_FFFF | 512MB |

From all incoming requests, TILER requests are filtered as having an address that fits:

- The address format in the TILER-specific address map given in Table 15-15, or
- The address format of the aliased view in the system address map given in Table 15-16, other requests are forwarded directly to the SDRAM controller in a TILER bypass mode.

Table 15-15. Address Format in the TILER-Specific Address Map

| 32 | 31 | 30 | 29 | 28 | 27 | 26 ... 4 | 3 ... 0 |
|----|-------------|----|----|------|----|-----------------|---------|
| T | Orientation | | | Mode | | Virtual address | |
| 1 | S | Y | X | M1 | M0 | A26 ... A4 | 0 |

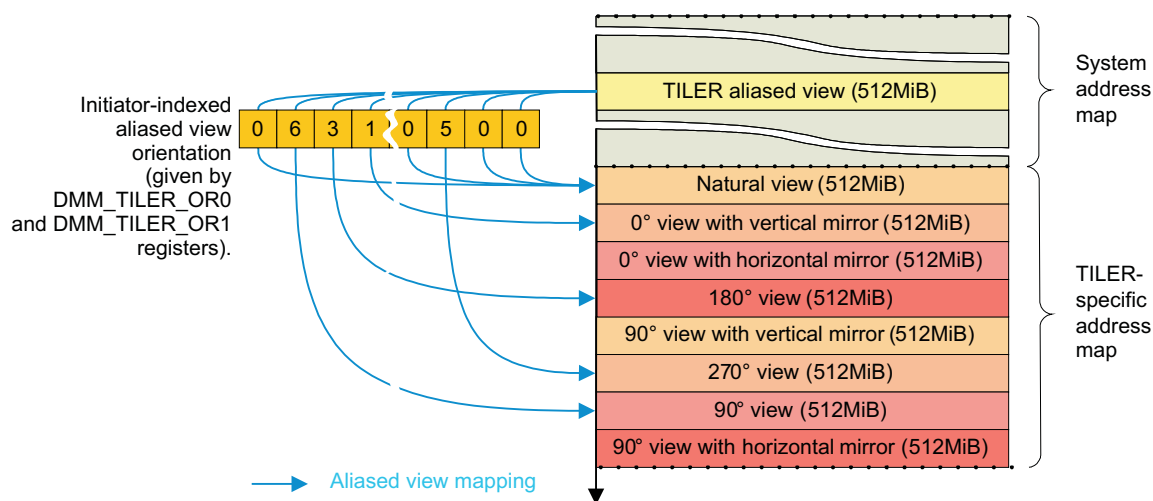

Table 15-16. Address Format of the TILER Aliased View in the System Address Map

| 32 | 31 | 30 | 29 | 28 | 27 | 26 ... 4 | 3 ... 0 |
|----|----------------|----|----|------|----|-----------------|---------|
| T | TILER aliasing | | | Mode | | Virtual address | |
| 0 | 0 | 1 | 1 | M1 | M0 | A26 ... A4 | 0 |

In these address formats:

- The 33rd bit, noted T, is aimed at distinguishing the standard 4-GiB system address map from the 4-GiB TILER-specific address map
- The orientation bits, noted S, \bar{Y} and \bar{X} , define the request orientation as specified in [Table 15-12](#)
- The mode bits, noted M1 and M0, define the request mode as specified in [Table 15-11](#)
- The remaining 27 bits, noted A0 to A26, define the mode and orientation specific virtual address as defined in [Figure 15-16](#), [Figure 15-17](#), and [Figure 15-18](#).

The orientation of the aliased TILER view is extracted from an initiator-indexed look-up table, as shown in [Figure 15-36](#).

Figure 15-36. TILER Aliased View Orientation

sdram-057

As illustrated in [Figure 15-36](#), an internal initiator-indexed lookup table is storing the current orientation of the aliased view for each initiator.

When an interconnect request hits the TILER aliased view in the system address map, the request initiator orientation is extracted from the lookup table and the request address is translated accordingly to this orientation - the T bit is set and bits [31:29] are replaced with the orientation.

Regarding the dimensioning of this lookup table, given that:

- Initiators accessing simultaneously multiple views use the TILER-specific address map,
- Many initiators either do not need to access any view or can be restricted to only accessing the natural view,

only a limited number of initiators are likely to dynamically modify the orientation of its aliased TILER view. Then, the orientation lookup table is limited to 16 entries. These 16 orientation entries are mapped on the two 32-bit [DMM_TILER_OR0](#) and [DMM_TILER_OR1](#) registers.

The first eight entries of the lookup table are mapped in the [DMM_TILER_OR0](#) register, and the last eight entries in the [DMM_TILER_OR1](#) register. Therefore, given an index x, the orientation related to this index is given in the ORx field.

Each of these two registers is split in eight 4-bit fields, each field mapping an entry of the lookup table with:

- A S, \bar{Y} , \bar{X} orientation code on the 3 LSBs

- A \overline{W} field-specific active-low local write enable bit, always read as 0, on the MSB

The registers fields that correspond to initiators not needing any dynamic configuration of their aliased view orientation must be specified as reserved fields, and only written with zeros.

The role of the \overline{W} bit is to allow the modification of a single entry without requiring a read-modify-write sequence. This approach is then much friendlier:

- In a system where multiple initiators are capable of modifying their own fields in the registers
- With initiators unable to make the read-modify-write sequence such as DMA.

Still, the \overline{W} bit is active-low to keep the compatibility with the usual read-modify-write sequence. When reading an aliased view orientation register, as all its \overline{W} bits are read as 0, if these bits are untouched by the modification - as they should be -, writing back the modified register updates all orientation fields of the register.

15.2.3.6.3 TILER Guidelines for Initiators

15.2.3.6.3.1 Buffered Raster-Based Initiators

15.2.3.6.3.1.1 Buffer Size

The necessary minimum buffer size depends on the initiator support in terms of:

- Element size
- Orientation
- Maximum number of elements per line in all supported element sizes and orientations and on the SDRAM memory pre-fetch size.

Let N be the maximum number of elements per line for a given mode - element size - and orientation, P be the SDRAM memory pre-fetch size in bytes, and max be the function returning the maximum of the two parameters, the minimum necessary line buffer size to handle all resolutions in a given mode and orientation is given in [Table 15-17](#).

Table 15-17. Minimum Buffer Size to Efficiently Handle Lines of up to N Elements

| | 0° or 180° orientation (S=0) | 90° or 270° orientation (S=1) |
|-------------|------------------------------|-------------------------------|
| 8-bit mode | 4 x N bytes | $max(4, P/4) \times N$ bytes |
| 16-bit mode | None | $max(8, P/2) \times N$ bytes |
| 32-bit mode | None | $max(8, P/2) \times N$ bytes |

This minimal buffer size can only be reached with an advanced FIFO management scheme. The standard ping-pong buffer requires twice this buffer size.

NOTE: Given their nature, field accesses to an interlaced frame-buffer require buffers twice as small as in the standard progressive case.

For instance, an initiator that shall handle only a single progressive frame-buffer in any orientation of:

- Up to 1920x1080 in YUV 4:2:0
- Up to 1600x1200 in 16-bit RGB565
- Up to 800x600 in 32-bit ARGB

requires a line buffer of at least 15360 bytes since:

- $4 \times 1920 + 4 \times 2960 = 15360$ bytes are required for a 3-plane YUV 4:2:0 frame of 1920x1080
 - $4 \times 1920 + 8 \times 960 = 15360$ bytes are required for a 2-plane YUV 4:2:0 frame of 1920x1080
 - $8 \times 1600 = 12800$ bytes are required for a 16-bit RGB565 frame of 1600x1200
 - $8 \times 800 = 6400$ bytes are required for a 32-bit ARGB frame of 800x600
- and a line buffer of at least 30720 bytes when using a simple ping-pong buffer scheme.

15.2.3.6.3.1.2 Performance

Table 15-18 gives the ratio of effective data to transferred data at the external memory interface for these buffered raster-based initiators in each mode and orientation, when using an up-to-32-bit DDR, lpDDR or lpDDR2 SDRAM memory - or an up-to-16-bit DDR2 memory.

Table 15-18. Memory Data Payload for Buffered Raster-Based Initiators on up-to-32-bit DDR, lpDDR, or lpDDR2

| | 0° or 180° Orientation (S = 0) | | 90° or 270° Orientation (S = 1) | |
|-------------|--------------------------------|------------|---------------------------------|------------|
| | Progressive | Interlaced | Progressive | Interlaced |
| 8-bit mode | 100% | 100% | 100% | 50% |
| 16-bit mode | 100% | 100% | 100% | 50% |
| 32-bit mode | 100% | 100% | 100% | 50% |
| Page mode | 100% | N/A | 100% | 100% |

When using 32-bit DDR, lpDDR or lpDDR2 SDRAM memories - or even 16-bit DDR, DDR2, lpDDR or lpDDR2 memories -, whenever all previous guidelines are fulfilled, then there is no penalty of any kind for these initiators to access a tiled object in any orientation, except for accesses to an interlaced frame in a 90° or 270° orientation where the memory bandwidth is twice the requested bandwidth.

When using up-to-32-bit DDR, lpDDR, lpDDR2 - or also up-to-16-bit DDR2 - SDRAM memories, all accesses, except interlaced accesses in a 90° or 270° orientation, are equally efficient and offer the full possible memory bandwidth.

Given its progressive nature, the page mode does not introduce any performance hit.

Table 15-19 gives the ratio of effective data to transferred data at the external memory interface for these buffered raster-based initiators in each mode and orientation, when using a 32-bit DDR2 or DDR3 memory.

Table 15-19. Memory Data Payload for Buffered Raster-Based Initiators on 32-bit DDR2 or DDR3

| | 0° or 180° Orientation (S = 0) | | 90° or 270° Orientation (S = 1) | |
|-------------|--------------------------------|------------|---------------------------------|------------|
| | Progressive | Interlaced | Progressive | Interlaced |
| 8-bit mode | 100% | 50% | 100% | 50% |
| 16-bit mode | 100% | 50% | 100% | 50% |
| 32-bit mode | 100% | 50% | 100% | 50% |
| Page mode | 100% | N/A | 100% | 100% |

When using 32-bit DDR2 or DDR3 SDRAM memories, whenever all previous guidelines are fulfilled, then there is no penalty of any kind for these initiators to access a tiled object in any orientation, except for accesses to an interlaced frame in any orientation where the memory bandwidth is twice the requested bandwidth.

When using DDR2 or DDR3 SDRAM memories, all accesses, except interlaced accesses, are equally efficient and offer the full possible memory bandwidth.

Similarly, the page mode does not introduce any performance hit.

15.2.4 DMM Use Cases and Tips

15.2.4.1 PAT Use Cases

There are five ways of using PAT:

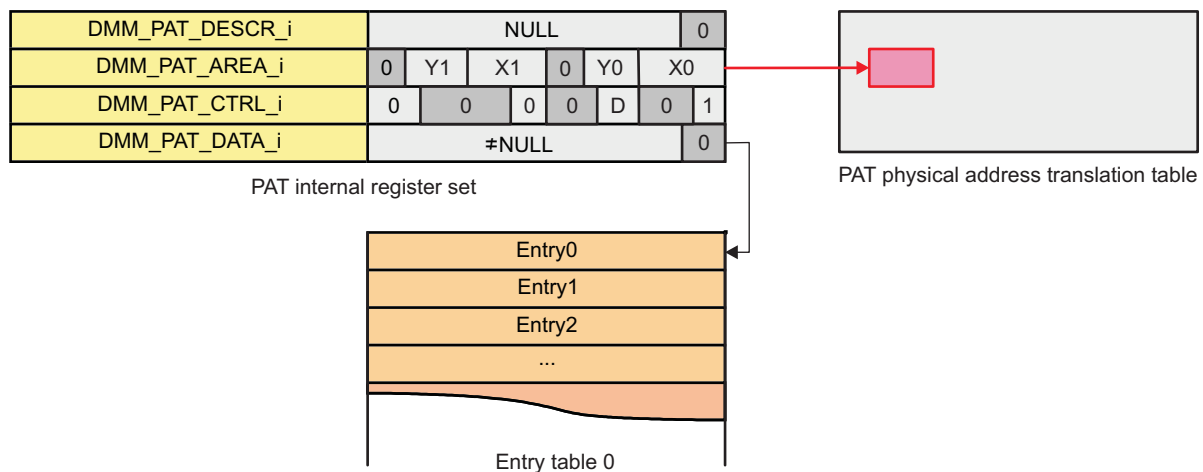

- Simple manual area refill
- Single auto-configured area refill
- Chained auto-configured area refill
- Synchronised auto-configured area refill
- Cyclic synchronized auto-configured area refill

15.2.4.1.1 Simple Manual Area Refill

These steps have to be performed to create the 16-byte aligned memory-mapped entry table containing all entries of the defined area (see [Figure 15-37](#)):

- Write the `DMM_PAT_AREA_i` register with the relevant (x0, y0) (x1, y1) area definition
- Write the `DMM_PAT_DATA_i` register with the physical address of the created entry table
- Write the `DMM_PAT_CTRL_i` register with the requested refill direction and assert the `DMM_PAT_CTRL_i[0]` START bit
- The refill is done when the `DMM_PAT_STATUS_i[3]` DONE bit is set
- A new refill can be initiated when the `DMM_PAT_STATUS_i[0]` READY bit is set

Figure 15-37. Simple Manual Area Refill Scheme

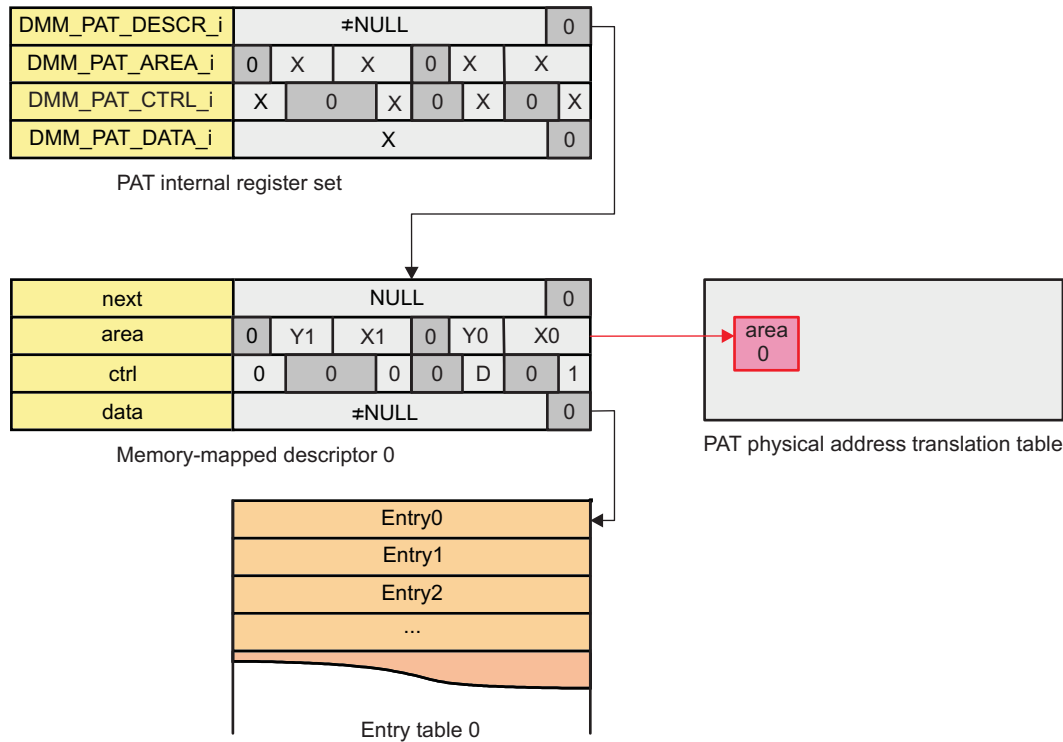

sdram-067

15.2.4.1.2 Single Auto-Configured Area Refill

These steps have to be performed to create the 16-byte aligned memory-mapped entry table containing all entries of the defined area (see [Figure 15-38](#)):

- Create a 16-byte aligned memory-mapped descriptor structure where:
 - the next field is set to NULL
 - the area field is set with the relevant (x0, y0) (x1, y1) area definition
 - the ctrl field is set with the requested direction D and the start bit asserted to start refilling as soon as this descriptor enters the PAT refill engine
 - the data field is set to the physical address of the created entry table
- The `DMM_PAT_DESCR_i` register with the physical address of the created descriptor
- The refill is done when the `DMM_PAT_STATUS_i[3]` DONE bit is set
- A new refill can be initiated when the `DMM_PAT_STATUS_i[0]` READY bit is set

Figure 15-38. Single Auto-Configured Area Refill Scheme

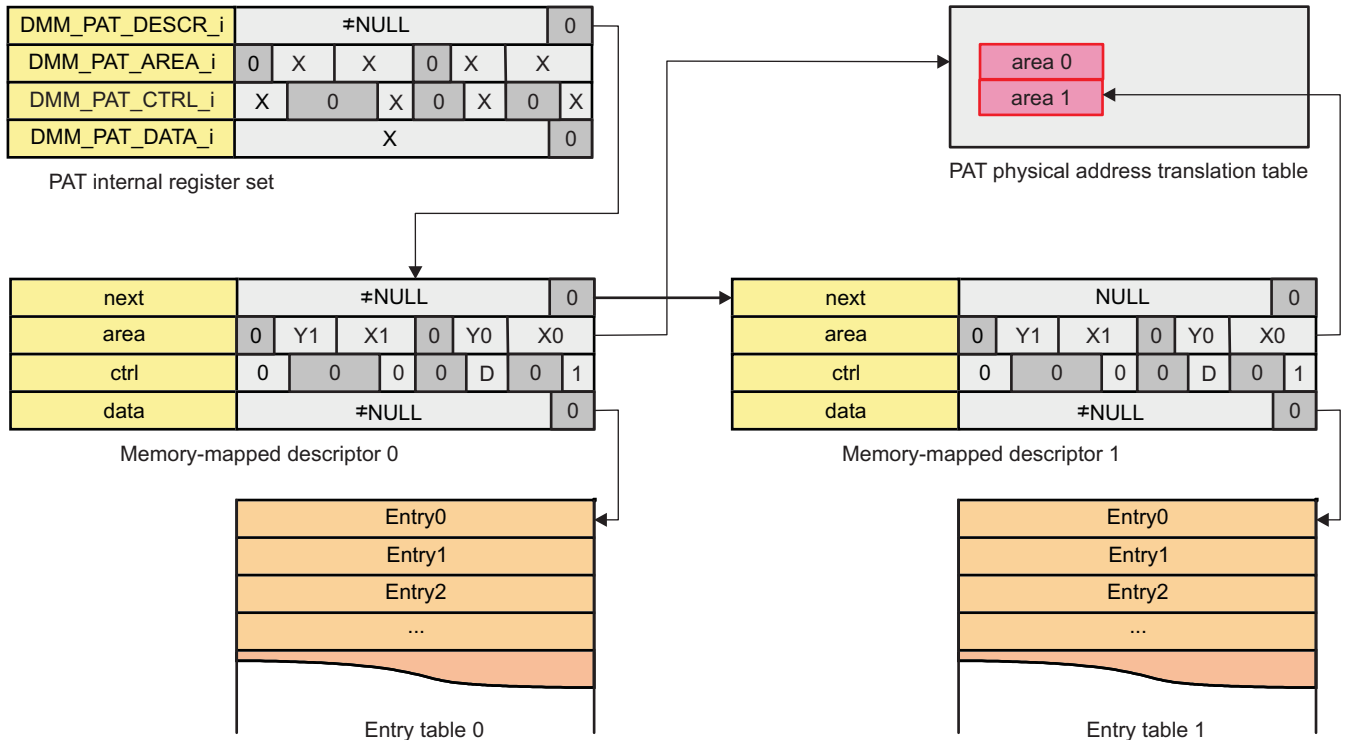

sdram-068

15.2.4.1.3 Chained Auto-Configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see [Figure 15-39](#)):

- Create one 16-byte aligned memory-mapped descriptor structures per area where:
 - the next field is set to the physical address of the next descriptor or NULL for the last one
 - the area field is set with the relevant (x0, y0) (x1, y1) area definition
 - the ctrl field is set with the requested direction D and the START bit asserted to start refilling as soon as the previous area refill is done
 - the data field is set to the physical address of the corresponding entry table
- Write the `DMM_PAT_DESCR_i` register with the physical address of the first created descriptor
- Each area refill is done when the `DMM_PAT_STATUS_i[3]` DONE bit is set
- All area refills are done when the `DMM_PAT_STATUS_i[0]` READY bit is set
- A new refill can be initiated when the `DMM_PAT_STATUS_i[0]` READY bit is set

Figure 15-39. Chained Auto-Configured Area Refill Scheme

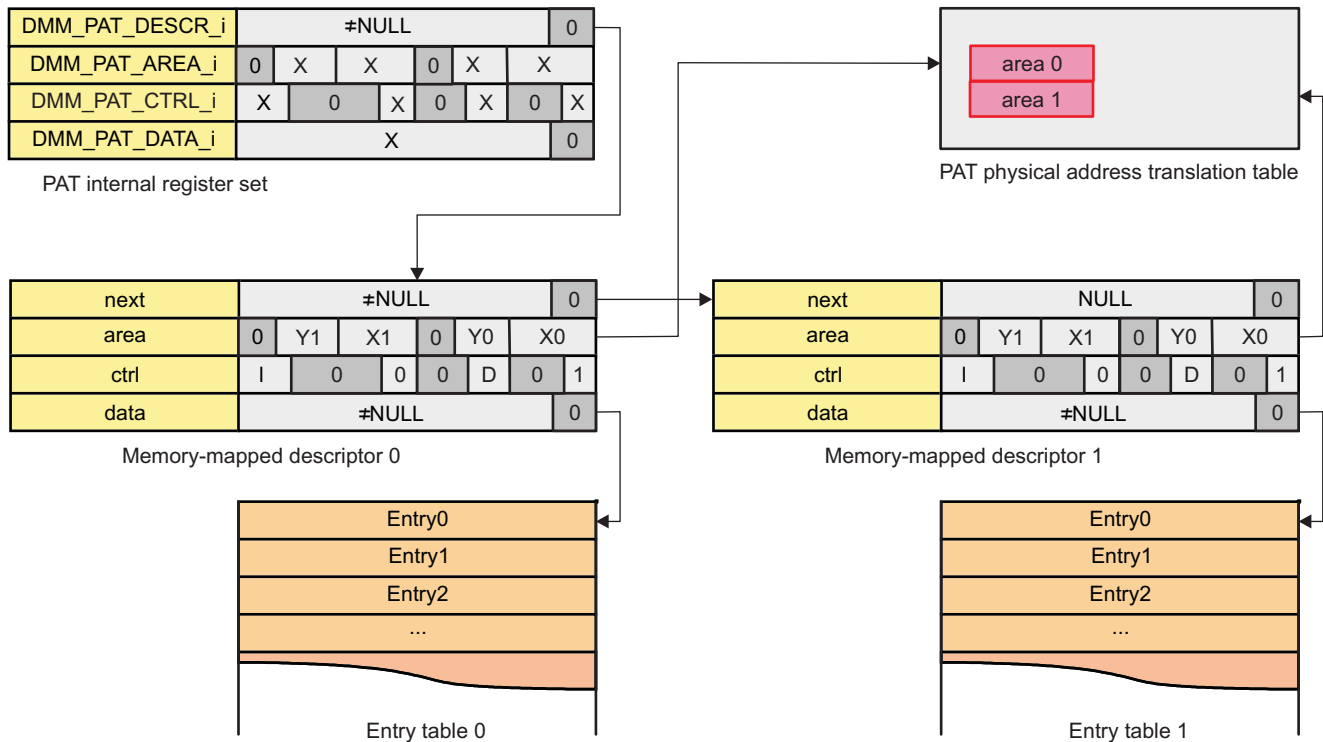

sdram-069

15.2.4.1.4 Synchronized Auto-Configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-40):

- Create one 16-byte aligned memory-mapped descriptor structures per area where:
 - the `next` field is set to the physical address of the next descriptor or `NULL` for the last one
 - the `area` field is set with the relevant (`x0`, `y0`) (`x1`, `y1`) area definition
 - the `ctrl` field is set with the synchronising initiator identifier `I`, the `SYNC` bit asserted, the requested direction `D`, and the `START` bit asserted to start refilling as soon as the previous area refill is done and initiator `I` has made one access in the previous area
 - the `data` field is set to the physical address of the corresponding entry table
- Write the `DMM_PAT_DESCR_i` register with the physical address of the first created descriptor
- Each area refill is done when the `DMM_PAT_STATUS_i[3]` `DONE` bit is set
- All area refills are done when the `DMM_PAT_STATUS_i[0]` `READY` bit is set
- A new refill can be initiated when the `DMM_PAT_STATUS_i[0]` `READY` bit is set

Figure 15-40. Synchronised Auto-Configured Area Refill Scheme

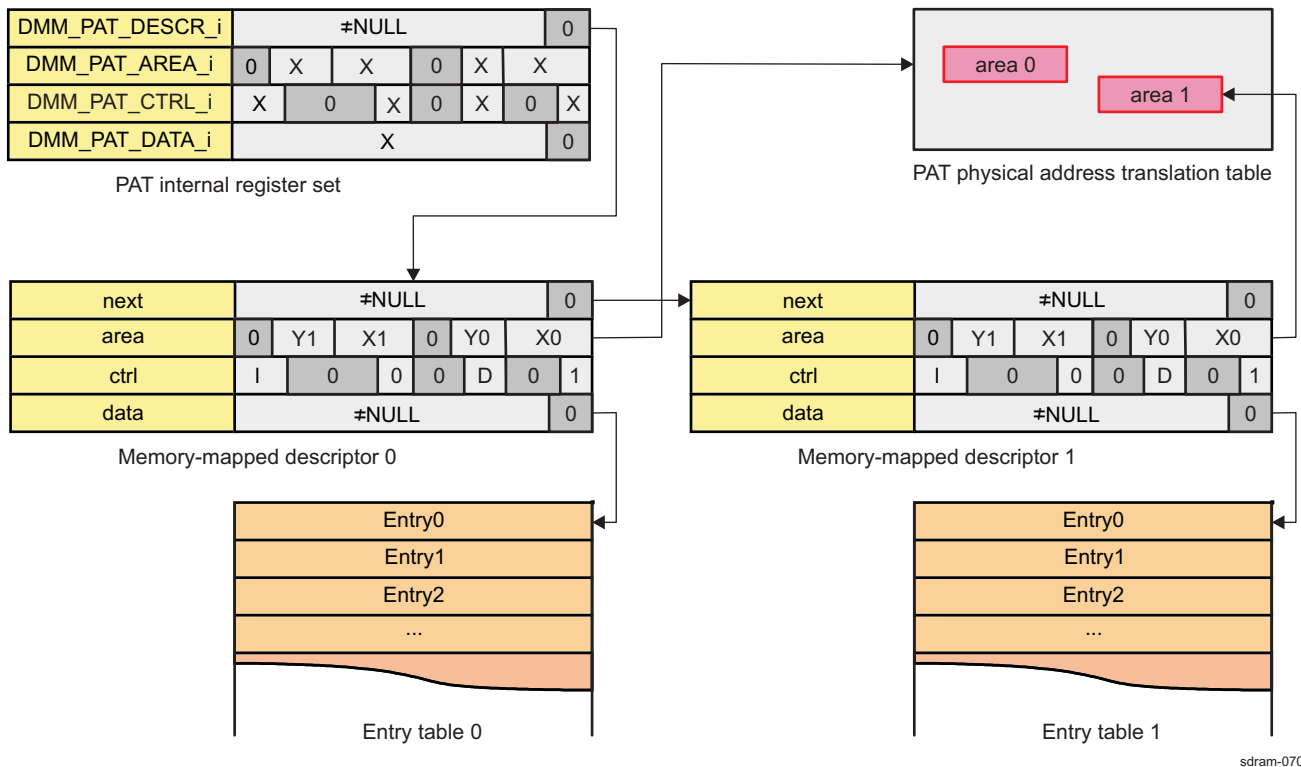

sdram-071

15.2.4.1.5 Cyclic Synchronized Auto-Configured Area Refill

These steps have to be performed to create one 16-byte aligned memory-mapped entry table per area containing the entries for the corresponding area (see Figure 15-41):

- Create one 16-byte aligned memory-mapped descriptor structures per area where:
 - the next field is set to the physical address of the next descriptor in the circular list
 - the area field is set with the relevant (x0, y0) (x1, y1) area definition
 - the ctrl field is set with the synchronising initiator identifier I, the SYNC bit asserted, the requested direction D, and the START bit asserted to start refilling as soon as the previous area refill is done and initiator I has made one access in the previous area
 - the data field is set to the physical address of the corresponding entry table
- Write the `DMM_PAT_DESCR_i` register with the physical address of the initial descriptor
- Each area refill is done when the `DMM_PAT_STATUS_i[3]` DONE bit is set
- A new refill can be initiated by writing any value to the `DMM_PAT_DESCR_i` to abort the current one

Figure 15-41. Cyclic Synchronized Auto-Configured Area Refill Scheme

sdram-070

NOTE: Never use circular lists of descriptors where all descriptors have the `DMM_PAT_CTRL_i[0]` START bit set and no synchronisation. This leads to an endless continuous refill.

15.2.4.2 Addressing Management with LISA

15.2.4.2.1 Case 1: Use of Only One Memory Controller

In this example, we assume that we have 1 GB of external memory evenly spread onto two address spaces. We also want the address range for address space 0 to start at offset 0x2000_0000.

Table 15-20. Address Definition

| Address Range | Memory Controller | Memory Controller Address Space ⁽¹⁾ | Memory Controller Address Range |
|----------------------------|-------------------|------------------------------------------------|---------------------------------|
| 0x8000_0000 to 0x9FFF_FFFF | EMIF1 | 0x1 | 0x0000_0000 to 0x1FFF_FFFF |
| 0xA000_0000 to 0xBFFF_FFFF | EMIF1 | 0x0 | 0x2000_0000 to 0x3FFF_FFFF |

⁽¹⁾ For memory controller address spaces, see Section 15.3.4.1.1, L3 Interface.

This configuration requires two non-overlapping sections to be set. They may be defined in any order since there is no concern with priority in this case, see Table 15-21:

Table 15-21. Configuration

| Bit Field | Section 0 (DMM_LISA_MAP_0) | Section 1 (DMM_LISA_MAP_1) |
|-------------------|----------------------------|----------------------------|
| [31:24] SYS_ADDR | 0x80 | 0xA0 |
| [22:20] SYS_SIZE | 0x5 | 0x5 |
| [19:18] SDRC_INTL | 0x0 (not applicable) | 0x0 (not applicable) |

Table 15-21. Configuration (continued)

| Bit Field | Section 0 (DMM_LISA_MAP_0) | Section 1 (DMM_LISA_MAP_1) |
|----------------------|----------------------------|----------------------------|
| [17:16] SDRC_ADDRSPC | 0x1 | 0x0 |
| [8] SDRC_MAP | 0x1 (only one controller) | 0x1 (only one controller) |
| [7:0] SDRC_ADDR | 0x00 | 0x20 |

To check if an address hits a section, use the eight upper address bits of the address and mask them with the hit mask: $2^8 - 2^{\text{SYS_SIZE}}$. If the result is equal to SYS_ADDR, the section is hit.

To define the physical address to be issued to the memory controller, use the eight upper address of the system address, mask them with the address mask: $2^{\text{SYS_SIZE}} - 1$, and OR them with SDRC_ADDR. This will give you the resulting eight upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: $2^8 - 2^5 = 0xE0$
- Masked upper address bits: 0x80 -> hits section 0
- Address mask: $2^5 - 1 = 0x1F$
- Masked upper address bits: 0x19
- OR with SDRC_ADDR: 0x19
- Physical address: 0x19AE_37F0

This request will be forwarded to address 0x19AE_37F0, address space 1 of the memory controller.

Request to address 0xB7FF_0340:

- Upper address bits: 0xB7
- Hit mask: $2^8 - 2^5 = 0xE0$
- Masked upper address bits: 0xA0 -> hits section 1
- Address mask: $2^5 - 1 = 0x1F$
- Masked upper address bits: 0x17
- OR with SDRC_ADDR: 0x57
- Physical address: 0x57FF_0340

This request will be forwarded to address 0x57FF_0340, address space 0 of the memory controller.

15.2.4.2.2 Case 2: Use of the Two Memory Controllers

In the case of 512 MB interleaved at 128-byte boundaries and 256 MB noninterleaved on a second memory controller, one address space per memory controller, we have the following scenario:

Table 15-22. Address Definition

| Address Range | Memory Controller | Memory Controller Address Space ⁽¹⁾ | Memory Controller Address Range |
|----------------------------|-----------------------------------------------------|------------------------------------------------|------------------------------------------------|
| 0x8000_0000 to 0x9FFF_FFFF | EMIF1 and EMIF2, interleaved at 128-byte boundaries | 0x0 on both controllers | 0x0000_0000 to 0x0FFF_FFFF on both controllers |
| 0xA000_0000 to 0xAFFF_FFFF | EMIF2 only | 0x0 | 0x1000_0000 to 0x1FFF_FFFF |

⁽¹⁾ For memory controller address spaces, see [Section 15.3.4.1.1, L3 Interface](#).

Two sections are used to map such a configuration, see [Table 15-23](#):

Table 15-23. Configuration

| Bit Field | Section 0 (DMM_LISA_MAP_0) | Section 1 (DMM_LISA_MAP_1) |
|------------------|----------------------------|----------------------------|
| [31:24] SYS_ADDR | 0x80 | 0xA0 |
| [22:20] SYS_SIZE | 0x5 | 0x4 |

Table 15-23. Configuration (continued)

| Bit Field | Section 0 (DMM_LISA_MAP_0) | Section 1 (DMM_LISA_MAP_1) |
|----------------------|----------------------------|----------------------------|
| [19:18] SDRC_INTL | 0x1 | 0x0 (not applicable) |
| [17:16] SDRC_ADDRSPC | 0x0 | 0x0 |
| [8] SDRC_MAP | 0x3 | 0x2 |
| [7:0] SDRC_ADDR | 0x00 | 0x10 |

Detecting a section hit is the same for the interleaved case as for the single controller case: to check if an address hits a section, use the eight upper address bits of the address and mask them with the hit mask: $2^8 - 2^{\text{SYS_SIZE}}$. If the result is equal to SYS_ADDR, the section is hit.

The physical address generation is modified for the interleaved case though. In case of a 256 bytes interleaving, the first chunk of 256 bytes is mapped to the first controller, the second chunk to the second controller, and so on. This results in system address bit 8 to be decoded as the controller indicator, 0 for the first controller and 1 for the second one (system address bit 7 would be used for interleaving at 128 bytes boundary, and bit 9 for 512 bytes). This bit is not included in the computed physical address, meaning the upper system address bits 9 to 31 are shifted to bits 8 to 30 when generating the physical address.

The rest of the address generation is handled the same as for the single controller case: to define the physical address to be issued to the memory controller, use the eight upper address of the system address, mask them with the address mask: $2^{\text{SYS_SIZE}} - 1$, and OR them with SDRC_ADDR. This will give you the resulting eight upper physical address bits. All lower address bits are forwarded unchanged.

Request to address 0x99AE_37F0:

- Upper address bits: 0x99
- Hit mask: $2^8 - 2^5 = 0xE0$
- Masked upper address bits: 0x80 -> hits section 0
- Address mask: $2^5 - 1 = 0x1F$
- Masked upper address bits: 0x19
- Full masked address: 0x19AE_37F0
- Bit 7 is 1 -> targets the second memory controller
- Full masked shifted address (suppressing bit 7): 0x0CD7_1BF0 (see [Section 15.2.4.2.2.1](#))
- OR upper physical address bits with SDRC_ADDR: 0x0CD7_1BF0
- Physical address: 0x0CD7_1BF0

This request will be forwarded to address 0x0CD7_1BF0, address space 0, of the second memory controller.

15.2.4.2.2.1 Address Upper Bits Shifting**Table 15-24. Address Upper Bits Shifting**

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|------------------------------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |
| Address Before Interleaving | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 |
| Address After Interleaving | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 0 |

15.2.5 DMM Basic Programming Model

The programming model section:

- Describes how objects can be addressed in all TILER modes and orientations
- Explains how the physical containers and physical address translation (PAT) look-up table (LUT) can be shared between different modes
- Does not give an exhaustive description of all TILER and DMM registers, because these are described in [Section 15.2.3.5, DMM](#) and [Section 15.2.3.6, TILER](#).

15.2.5.1 Global Initialization

This section identifies the requirements of initializing the surrounding modules when the DMM module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the DMM.

Table 15-25. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power, Reset and Clock Management (PRCM) | The module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management . |
| Dual Cortex™ - M3 microprocessor unit (MPU) | Cortex-M3 interrupt controller (INTC) configuration must be done to enable the interrupts from DMM module. See Chapter 17, Interrupt Controllers . |
| Dual Cortex™ - A9 MPU | Cortex-A9 INTC configuration must be done to enable the interrupts from DMM module. See Chapter 17, Interrupt Controllers . |
| L3 Interconnect | Data Interface |

15.2.5.2 DMM Module Global Initialization

This procedure initializes the DMM after a power-on reset.

Table 15-26. DMM Global Initialization

| Step | Register/ Bit Field / Programming Model | Value |
|--------------------------------------------------------|----------------------------------------------|-------|
| Configure the DMM for Smart-Idle power management mode | DMM_SYSCONFIG[3:2] IDLE_MODE | 0x2 |

15.2.5.3 DMM Operational Modes Configuration

15.2.5.3.1 Different Operational Modes

The TILER can be virtually accessed in four different modes, namely 8-bit, 16-bit, 32-bit and page modes. Each mode defines the element granularity to apply isometric transforms, as summarized in [Table 15-29](#)

Table 15-27. Coding and Description of TILER Modes

| Mode | Name | Granularity (element size) |
|------|---------------------|----------------------------|
| 0 | 8 - bit tiled mode | 8 bits |
| 1 | 16 - bit tiled mode | 16 bits |
| 2 | 32 - bit tiled mode | 32 bits |
| 3 | Page mode | 4096 bytes |

15.2.5.3.2 Configuration Settings and LUT Refill

Table 15-28. Configuration Settings and LUT Refill

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------------------------------------------------------------------------|--------------------------------------|-------|
| PAT configuration refill Engine 0 | DMM_PAT_CONFIG[0] MODE0 | xxx |
| PAT configuration refill Engine 1 | DMM_PAT_CONFIG[1] MODE1 | xxx |
| Set DMM PAT View register value for each initiator | DMM_PAT_VIEW0 Vx DMM_PAT_VIEW1 Vx | xxx |
| Set DMM PAT Write enable for the initiators | DMM_PAT_VIEW0 Wx DMM_PAT_VIEW1 Wx | xxx |
| Choosing container type and access method | DMM_PAT_VIEW_MAP_i | xxx |
| Define the base address of all view mappings | DMM_PAT_VIEW_MAP_BASE[31] BASE_ADDR | xxx |
| Set area definition for DMM physical address translator | DMM_PAT_AREA_i | xxx |
| Set physical address of the current table refill entry data or entry data when in manual mode | DMM_PAT_DATA_i[31:4] ADDR | xxx |
| Define the direction of this PAT table refill (S Y X), different from 0x011 | DMM_PAT_CTRL_i[6:4] DIRECTION | xxx |
| Start a PAT table refill | DMM_PAT_CTRL_i[0] START | 0x1 |

15.2.5.3.3 Interleaving Settings

Table 15-29. Interleaving Settings

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------|--------------------------------------|-------|
| Set DMM system section address MSB | DMM_LISA_MAP_i[31:24] SYS_ADDR | xxx |
| Set DMM system section size | DMM_LISA_MAP_i[22:20] SYS_SIZE | xxx |
| Set SDRAM controller interleaving mode | DMM_LISA_MAP_i[19:18] SDRG_INTL | xxx |
| Set SDRAM controller address space | DMM_LISA_MAP_i[17:16] SDRG_ADDRSPC | xxx |
| Set SDRAM controller mapping | DMM_LISA_MAP_i[9:8] SDRG_MAP | xxx |
| Set SDRAM controller address MSB | DMM_LISA_MAP_i[7:0] SDRG_ADDR | xxx |
| Enable/disable DMM memory mapping lock | DMM_LISA_LOCK[0] LOCK | xxx |

15.2.5.3.4 Aliased Tiled View Orientation Settings and LUT Refill

Table 15-30. Aliased Tiled View Orientation Settings and LUT Refill

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------------------------------------|----------------------------------------|-------|
| Set DMM TILER orientation for each initiator | DMM_TILER_OR0 ORx DMM_TILER_OR1 ORx | xxx |
| Set DMM TILER write enable for the initiators | DMM_TILER_OR0 Wx DMM_TILER_OR1 Wx | xxx |
| Define the base address of all view mappings | DMM_PAT_VIEW_MAP_BASE[31] BASE_ADDR | xxx |
| DMM PAT initiator for synchronisation | DMM_PAT_CTRL_i[31:28] INITIATOR | xxx |
| Set DMM PAT table reload synchronisation | DMM_PAT_CTRL_i[16] SYNC | xxx |
| Set DMM PAT LUT index | DMM_PAT_CTRL_i[9:8] LUT_ID | xxx |
| Define the direction of this PAT table refill (S Y X) | DMM_PAT_CTRL_i[6:4] DIRECTION | xxx |
| Start a PAT table refill | DMM_PAT_CTRL_i[0] START | 0x1 |

15.2.5.3.5 Priority Settings

Table 15-31. Priority Settings

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------|--------------------------------------------|-------|
| Set priority for each initiator | DMM_PEG_PRIO_k Px | xxx |
| Set write enable for P_PAT field | DMM_PEG_PRIO_PAT[4]W_PAT | xxx |
| Set priority for PAT engine | DMM_PEG_PRIO_PAT[2:0]P_PAT | xxx |

15.2.5.3.6 Error Handling

Table 15-32. Error Handling

| Step | Register/Bit Field/Programming Model | Value |
|---------------------------------------------|-------------------------------------------------------------------------------------------|-------|
| Enable interrupt for selected type of error | DMM_PAT_IRQENABLE_SET[15:9] DMM_PAT_IRQENABLE_SET[7:0] | xxx |

15.2.5.3.7 PAT Programming Model

The purpose of the PAT is to map the tiled data anywhere in the 4GB physical address range, with a PAGE granularity. (The TILER page is the granularity of physical memory allocation in TILER container. Each page is 4kiB).

A PAT view is defining the kind of physical address translation to perform for each of the page, 8-bit, 16-bit and 32-bit mode accesses. Each mode in each PAT view can be programmed in 2 different modes (direct translation and indirect translation).

15.2.5.3.7.1 PAT in Direct Translation Mode

In this mode, the PAT performs a translation of the 128MB virtual container as a whole in the physical address space (that is, in the SDRAM). This mode is used only for debug or in case of a DMM without PAT module.

15.2.5.3.7.2 PAT in Indirect Translation Mode

This is the most commonly mode used. In this mode, the PAT performs a translation of each 4kB page individually. In this way the 128MB virtual address space can be scattered in the whole 2GB of the physical address space. This is achieved by using a 32678-word look-up table (LUT) which converts each page index (32768 possible values) into 19 address bits representing this page address in the physical memory. The main characteristic of this mode is: no constraint on the use of the physical memory except that it is using a multiple of 4kB areas located at 4kB boundaries in the physical memory.

In this mode the translation vector is found in the internal 32-k entry physical address translation vector table at the index given by bits 12 to 26 of the input virtual address, and the CONT_x = 0.

Programming sequence:

- Set in [DMM_PAT_VIEW0](#) (or [DMM_PAT_VIEW1](#) depending on the L3 CONN_ID of the initiator which is supposed to perform the tiled accesses) with the appropriate value. For example, if the L3 CONN_ID equals 0, then the register [DMM_PAT_VIEW0](#) should be programmed with the value 0x0000_0001 (PAT view 1 selected for initiator 0)
- [DMM_PAT_VIEW_MAP_BASE\[31\]](#) = 0x8000_0000 (should always be programmed at 1 to select the upper 2GB of the physical address space which corresponds to the external memory)
- set all 16bit tiled accesses in indirect translation mode by setting at least the field ACCESS_16 at 1 ([DMM_PAT_VIEW_MAP_1](#) = 0x0000_8000), program [DMM_PAT_VIEW_MAP_1](#) at 0x8080_8080.

15.2.5.4 Addressing an Object in Tiled Mode

The purpose of this sub-section is to describe how a frame-buffer with a top-left pixel located at (x_0, y_0) in the natural view container and a bottom right pixel located at (x_1, y_1) in the natural view container is addressed in any tiled mode and orientation.

15.2.5.4.1 Frame Buffer Addressing

NOTE: In this sub-section, the (x, y) coordinates are given in pixel units.

Given a (S, \bar{Y}, \bar{X}) orientation, the (x, y) coordinates of the first pixel of the frame in the oriented view (with W the width and H the height in pixels of the container in the considered frame mode) is:

$(x, y) = (x_{or}, y_{or})$ when S , (y_{or}, x_{or}) otherwise

with:

$x_{or} = x_0$ when \bar{X} , $W-1-x_1$ otherwise

$y_{or} = y_0$ when \bar{Y} , $H-1-y_1$ otherwise

Given a (M_1, M_0) TILER mode where $M_1 \neq 0$ or $M_0 \neq 0$, the size in bytes of a pixel is $2^{2M_1+M_0}$.

Therefore, given a (S, \bar{Y}, \bar{X}) orientation and a (M_1, M_0) TILER mode where $M_1 \neq 0$ or $M_0 \neq 0$, the byte offset of the base address of the considered oriented frame in its container is:

base_address($(x_0, y_0), (x_1, y_1), (S, \bar{Y}, \bar{X}), (M_1, M_0)$) = $(y_{or}W + x_{or}) P_5$ when S , $(x_{or}H + y_{or}) P_5$ otherwise

with:

$x_{or} = x_0$ when \bar{X} , $W-1-x_1$ otherwise

$y_{or} = y_0$ when \bar{Y} , $H-1-y_1$ otherwise

$P_5 = 2^{2M_1+M_0}$

In its natural orientation, the TILER container consists of 8192 lines of 16384 pixels of 8 bits, or 4096 lines of 16384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32-bits.

Figure 15-42. Example of 8-Bit Frame-Buffer Addressing in any Orientation

sdram-075

This frame-buffer address generation is independent from the page size. For instance, the 8-bit frame-buffer described in Figure 15-42 and ranging from the top-left pixel located at $(16, 32)$ to the bottom-right pixel located at $(223, 159)$ in the natural orientation view, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in Table 15-33.

Table 15-33. 29-Bit View Address Offset and 33-Bit Full TILER Address for an 8-Bit Frame-Buffer

| S | \bar{Y} | \bar{X} | x_{or} | y_{or} | 29-bit address offset in view | Full 33-bit TILER address |
|---|-----------|-----------|----------|----------|-------------------------------|---------------------------|
| 0 | 0 | 0 | 16 | 32 | 00080010h | 100080010h |
| 0 | 0 | 1 | 16160 | 32 | 00083F20h | 120083F20h |
| 0 | 1 | 0 | 16 | 8032 | 07D80010h | 147D80010h |
| 0 | 1 | 1 | 16160 | 8032 | 07D83F20h | 167D83F20h |
| 1 | 0 | 0 | 16 | 32 | 00020020h | 180020020h |
| 1 | 0 | 1 | 16160 | 32 | 07E40020h | 1A7E40020h |
| 1 | 1 | 0 | 16 | 8032 | 00021F60h | 1C0021F60h |
| 1 | 1 | 1 | 16160 | 8032 | 07E41F60h | 1E7E41F60h |

In this example the TILER is addressed in 8-bit mode, which translates to addresses with all mode bits - bits 27 and 28 - cleared in both the 29-bit address offset in view and full 33-bit TILER address.

15.2.5.4.2 TILER Page Mapping

Let:

- c ($c = 0, 1$ or 2) be the TILER page configuration (0 for 4 kiB, 1 for 16 kiB and 2 for 64 kiB pages)
- (x_0, y_0) be the top left pixel and (x_1, y_1) be the bottom right pixel of a frame in its natural orientation
- W be the width and H the height in pixels of the container in the considered frame mode

The top left page coordinate (P_{x0}, P_{y0}) and bottom right page coordinates (P_{x1}, P_{y1}) corresponding to the frame are given by: $P_{x0} = (64 \cdot x_0 \cdot 2^{2-c}) / W$, $P_{y0} = (32 \cdot y_0 \cdot 2^{2-c}) / H$, $P_{x1} = (64 \cdot x_1 \cdot 2^{2-c}) / W$ and $P_{y1} = (32 \cdot y_1 \cdot 2^{2-c}) / H$.

In its natural orientation, the TILER container consists of 8192 lines of 16384 pixels of 8 bits, or 4096 lines of 16384 pixels of 16 bits, or 4096 lines of 8192 pixels of 32-bits.

NOTE: The page area type has the exact same structure as the [DMM_PAT_AREA_i](#) registers. For instance, the 8-bit frame-buffer described in [Figure 15-42](#) and ranging from the top-left pixel located at (16, 32) to the bottom-right pixel located at (223, 159) in the natural orientation view, is mapped from the top-left page located at P0,0 to the bottom-right page located at P3,2.

15.2.5.5 Addressing an Object in Page Mode

In page mode, the orientation only modifies the sequence of accessed pages, not their content. In this respect the orientation shall be seen as a way to optimise the 1D object allocation in a TILER container by allowing a 1D object spanning on multiple pages to map a set of adjacent pages in any direction. For instance, a 1.25 MiB object, mapped on 320 pages of 4 kiB can be allocated in a TILER container in any of the eight orientations, see [Section 15.2.3.6.1.7.3, Element Ordering in the TILER Container](#).

The initial page can be chosen freely among all pages. In this respect, the address offset of a page in a TILER container is expressed as:

Let:

- c ($c = 0, 1$ or 2) be the TILER page configuration (0 for 4 kiB, 1 for 16 kiB and 2 for 64 kiB pages)
- (S, \bar{Y}, \bar{X}) be the orientation of the considered 1D object in page mode
- (P_x, P_y) be the coordinate of the initial page in the natural orientation view

The byte offset of the base address of the considered initial page in its oriented container is:

$base_address((P_x, P_y), (S, \bar{Y}, \bar{X})) = 4096 \cdot (64 \cdot y_{or} \cdot 2^{2-c} + x_{or}) \cdot 2^{2-c}$ when S , $4096 \cdot (32 \cdot x_{or} \cdot 2^{2-c} + y_{or}) \cdot 2^{2-c}$ otherwise with:

$x_{or} = P_x$ when \bar{X} , $64 \cdot 2^{2-c} - 1 - P_x$ otherwise

$y_{or} = P_y$ when \bar{Y} , $32 \cdot 2^{2-c} - 1 - P_y$ otherwise

For instance, a 1-D object starting from the page P32,63 in the natural orientation view on a DMM using 4-kiB pages, corresponds to the 29-bit view address offsets and full 33-bit TILER addresses given in [Table 15-34](#).

Table 15-34. 29-Bit View Address Offset and 33-Bit Full TILER Address for a 1D Object

| S | \bar{Y} | \bar{X} | x_{or} | y_{or} | 29-bit address offset in view | Full 33-bit TILER address |
|---|-----------|-----------|----------|----------|-------------------------------|---------------------------|
| 0 | 0 | 0 | 32 | 63 | 1BF20000h | 11BF20000h |
| 0 | 0 | 1 | 223 | 63 | 1BFDF000h | 13BFDF000h |
| 0 | 1 | 0 | 32 | 64 | 1C020000h | 15C020000h |
| 0 | 1 | 1 | 223 | 64 | 1C0DF000h | 17C0DF000h |
| 1 | 0 | 0 | 32 | 63 | 1903F000h | 19903F000h |
| 1 | 0 | 1 | 223 | 63 | 1EFBF000h | 1BEFBF000h |
| 1 | 1 | 0 | 32 | 64 | 19040000h | 1D9040000h |
| 1 | 1 | 1 | 223 | 64 | 1EFC0000h | 1FEFC0000h |

In this example the TILER is addressed in page mode, which translates to addresses with mode bits - bits 27 and 28 - set in both the 29-bit address offset in view and full 33-bit TILER address.

15.2.5.6 Sharing Containers Between Different Modes

When allocating objects in TILER containers, some care must be taken to ensure that any two objects do not physically overlap.

In this respect, and to ease the object allocation and de-allocation, it is strongly advised to only share a TILER page for different objects that:

- Belong to the same mode and
- That have the exact same lifetime - that are allocated and de-allocated simultaneously.

Two objects of different modes can physically overlap if:

- One physical page is mapped twice in two different locations of the DMM LUT
- The two objects share the DMM LUT and the intersection of their two page set is non empty.

These two issues can be easily avoided by only allocating a physical page once in the DMM LUT.

The second issue is a bit trickier, especially if the allocation of objects in the various TILER containers has to be dynamic. Managing the fragmentation within a flat memory model in a space-constrained system is not straightforward - and is the main reason for the existence of memory management units in most current processors - but adding yet another constraint to the problem - the y dimension - makes it really difficult.

Coming back to the CPU-analogy, the memory fragmentation issue has been mostly solved by:

- Using a virtual memory space much larger than the actual physical memory space,
- Using virtual-to-physical translation system

to allow contiguous virtual memory allocation when:

- Sufficient physical memory is available,
- The larger contiguous physical buffer is smaller than the requested memory allocation.

Similarly, the DMM answer to this object allocation in the TILER containers is two-folds:

1. The DMM has to be dimensioned to have sufficient virtual address space in all modes to permit a static allocation of a pool of virtual buffers in all TILER modes for all TILER-aware initiators
2. Each TILER-aware initiator has to dynamically manage its own pool of virtual buffers.

15.2.6 DMM Register Manual

This section provides information about the DMM instance in this product. [Table 15-36](#) provides a summary of the DMM registers. The remaining parts of this section describe the registers within the module instance.

15.3 EMIF Controller

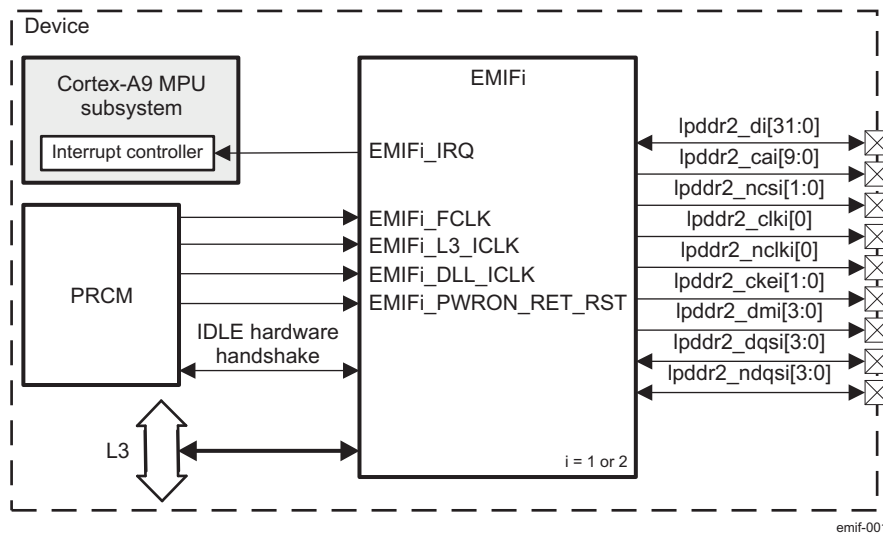

This section describes the features and functions of the external memory interface (EMIF) module of the device.

15.3.1 EMIF Module Overview

The EMIF module provides connectivity between the device and the LPDDR2-type memories and manages data bus read/write accesses between external memories, the microprocessor unit (MPU), and the direct memory access (DMA) controller.

The device includes two EMIF controllers. Figure 15-43 shows an overview of the EMIF module.

Figure 15-43. EMIF Module Overview

15.3.1.1 EMIF Module Main Features

The EMIF module supports the following features:

- JEDEC standard compliant LPDDR2-SDRAM (S2 and S4) and LPDDR2-NVM devices.
- Two GB SDRAM address range over two chip-selects (1GB per CS) (configurable with the DMM module, see Section 15.2, *Dynamic Memory Manager* for more information)
- Two independent chip-selects with their corresponding register sets and independent page tracking
- Both chip-selects must have the same memory type and size if they are both SDRAM or both NVM. LPDDR2-SDRAM can be used in parallel with LPDDR2-NVM and can have a different size.
- Flexible address muxing scheme which permit to choose different bank mapping allocation by configuring the bank, column and row address decoding ordering
- 16 or -32-bit data path to external SDRAM memory
- LPDDR2 devices with 1, 2, 4 or 8 of internal banks
- Data bus widths:
 - 128-bit L3 interconnect Data Bus Width
 - 16 and 32-bit SDRAM Data Bus Width
- CAS latencies: 3, 4, 5, 6, 7 and 8
- 256, 512, 1024, and 2048-word page sizes
- Burst lengths: 8
- Sequential burst type
- SDRAM auto initialization from reset or configuration change
- Bank Interleaving across both the chip-selects if same memory type

- Self Refresh and Precharge Power-down modes for low power (per chip-select, manual entry/exit Self-Refresh and Deep Power-down modes)
- Deep Power-down mode for low power
- Partial Array Self Refresh and Temperature Controlled Self Refresh modes for low power. Temperature Controlled Self Refresh is only supported for mobile SDRAM having on-chip temperature sensor.
- Prioritized refresh
- Programmable SDRAM refresh rate and backlog counter
- Output impedance (ZQ) calibration
- Temperature monitoring

15.3.1.2 Not supported Features

EMIF module does not support :

- Interleave burst type
- Auto precharge
- Active Power-down
- Per-bank refreshes for LPDDR2-SDRAM

15.3.1.3 EMIF Overall Architecture

Figure 15-44 shows the EMIF connection with the surrounding modules.

Figure 15-44. EMIF Overall Architecture

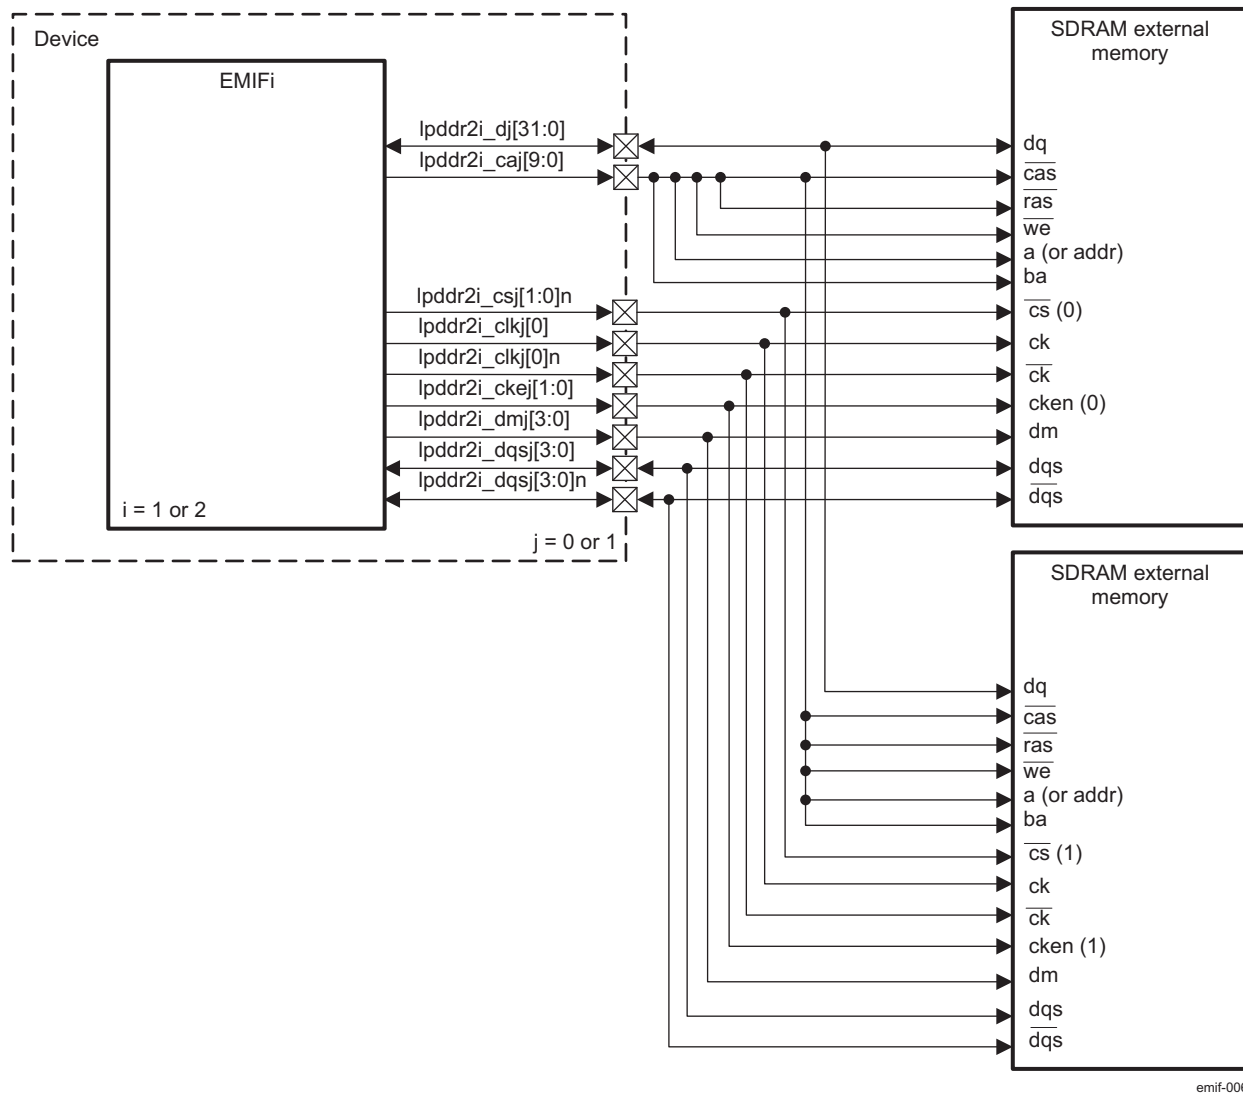

emif-007

15.3.2 EMIF Environment

This section describes the EMIF application fields from an environment point of view (external connections).

Figure 15-45 shows an the EMIF generic configuration.

Figure 15-45. EMIF Generic Configuration

emif-006

15.3.2.1 EMIF Signals

Table 15-93 describes the module signals and specifies their links to functions.

Table 15-93. I/O Signals

| Signal | I/O ⁽¹⁾ | Description |
|----------------------|--------------------|----------------------------------|
| EMIF1 | | |
| $lpddr21_dq[31:0]$ | I/O | Data bus |
| $lpddr21_ca[9:0]$ | O | Double data rate command/address |
| $lpddr21_ncs[1:0]$ | O | Chip-selects 1-0 (active low) |
| $lpddr21_clk$ | O | Clock |
| $lpddr21_nclk$ | O | Clock invert |
| $lpddr21_cke[1:0]$ | O | Clock enables 1-0 |
| $lpddr21_dm[3:0]$ | I/O | Data mask |
| $lpddr21_dqs[3:0]$ | I/O | Data strobe |
| $lpddr21_ndqs[3:0]$ | I/O | Data strobe invert |

⁽¹⁾ I = Input; O = Output

Table 15-93. I/O Signals (continued)

| Signal | I/O ⁽¹⁾ | Description |
|-------------------|--------------------|----------------------------------|
| EMIF2 | | |
| lpddr22_dq[31:0] | I/O | Data bus |
| lpddr22_ca[9:0] | O | Double data rate command/address |
| lpddr22_ncs[1:0] | O | Chip-selects 1-0 (active low) |
| lpddr22_clk | O | Clock |
| lpddr22_nclk | O | Clock invert |
| lpddr22_cke[1:0] | O | Clock enables 1-0 |
| lpddr22_dm[3:0] | I/O | Data mask |
| lpddr22_dqs[3:0] | I/O | Data strobe |
| lpddr22_ndqs[3:0] | I/O | Data strobe invert |

CKE memory pin is dynamically driven by the SDRAM controller according to the memory interface activity. Each chip-select has its own CKE pin, so that each chip-select can be independently controlled in terms of power-down mode, deep power-down mode and self refresh.

Each LPDDR2 channel, that is, each EMIF controller may be connected to two external LPDDR2 memories. See [Section 15.2](#), *DMM* of the device for more information.

15.3.3 EMIF Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 15-46 shows the EMIF1 module integration in the device.

Figure 15-46. EMIF1 Integration

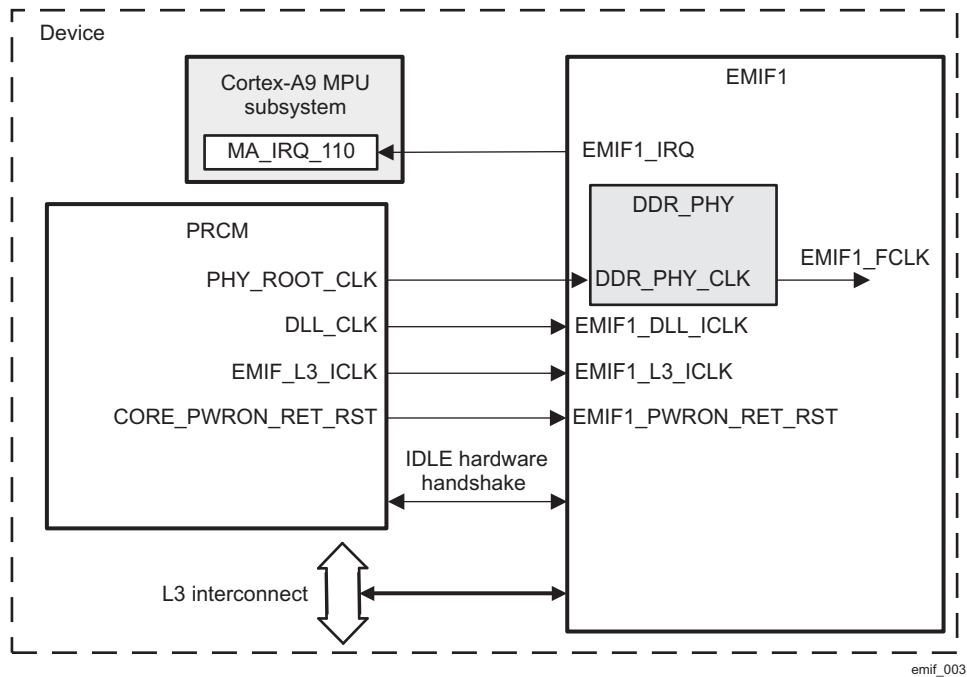

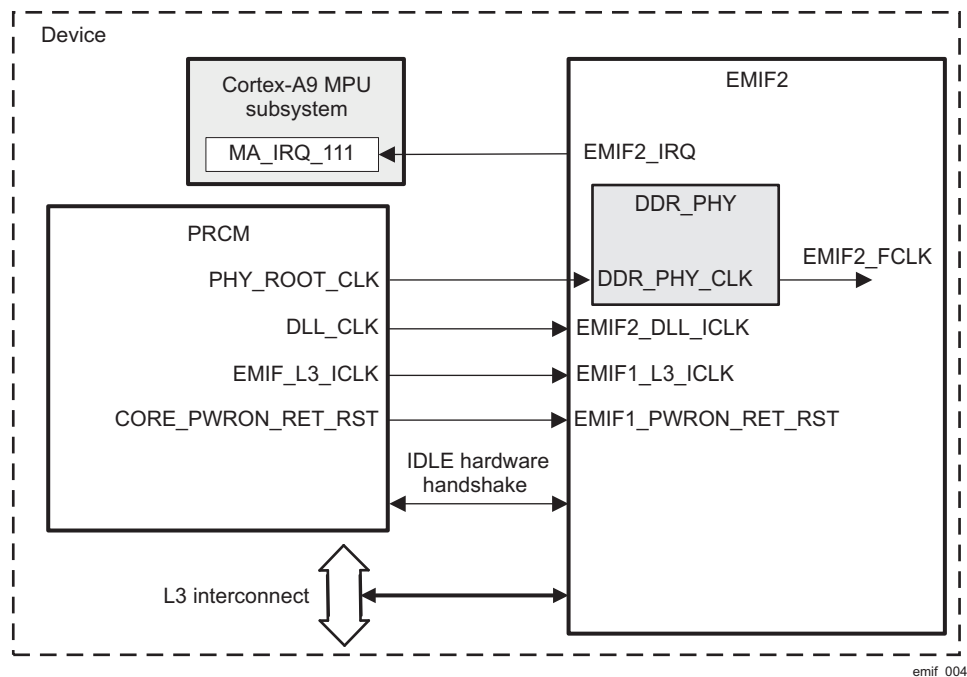

Figure 15-47 shows the EMIF2 module integration in the device.

Figure 15-47. EMIF2 Integration

NOTE: DDR_PHY_CLK is equal to PHY_ROOT_CLK divided by 2. EMIF_i_FCLK is equal to DDR_PHY_CLK divided by 2.

For more information about the EMIF clocking scheme, see [Chapter 3, Power, Reset, and Clock Management](#).

NOTE: For more information about the IDLE hardware handshake, see [Chapter 3, Power, Reset, and Clock Management](#) of the device.

Table 15-94 through Table 15-96 summarize the integration of the module in the device.

Table 15-94. Integration Attributes

NOTE: About interrupt source description, see [Section 15.3.4.5, Interrupt Requests](#).

15.3.4 EMIF Functional Description

15.3.4.1 Block Diagram

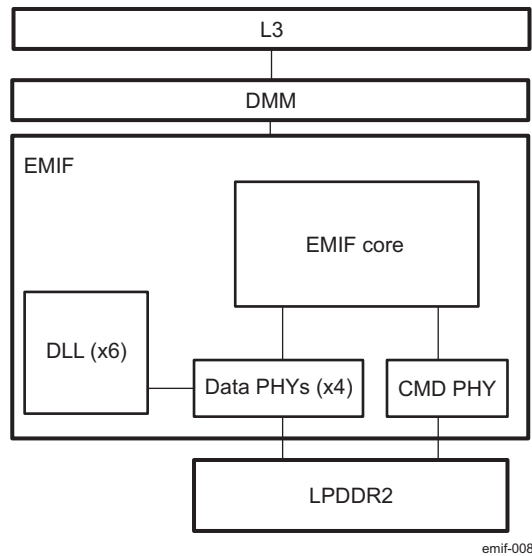

EMIF is a L3-bus peripheral providing an interface to LPDDR2 memories.

Figure 15-48 shows the interconnection between the EMIF module and the other modules.

DLLs are used to delay the input DQS signals during reads, so that these strobe signals can be used to latch incoming data on the DQ pins, as required by the LPDDR2 standard.

PHYS are hard macros that convert single data rate (SDR) signals to double data rate (DDR).

Figure 15-48. EMIF Block Diagram

15.3.4.1.1 L3 Interface

EMIF supports two local interfaces - one that connects to the System Interconnect and the other that connects to a Low-latency Master. These interfaces are used to request all external memory device accesses, to access the EMIF registers, and to transfer all data to/from the EMIF controller. Table 15-97 shows the MAddrSpace mapping to different chip-selects.

Table 15-97. MAddrSpace Mapping to Chip-Selects

| MAddrSpace ⁽¹⁾ | Chip-Select | Description |
|---------------------------|-------------|-------------------------------------------|
| 0x0 | CS[1:0] | SDRAM(s) |
| 0x1 | CS1 | LPDDR2-NVM (can be connected to CS1 only) |
| 0x2 | N/A | Reserved |
| 0x3 | N/A | Internal registers |

⁽¹⁾ See DMM_LISA_MAP_i [17:16] SDRC_ADDRSPC register in Section 15.2, Dynamic Memory Manager.

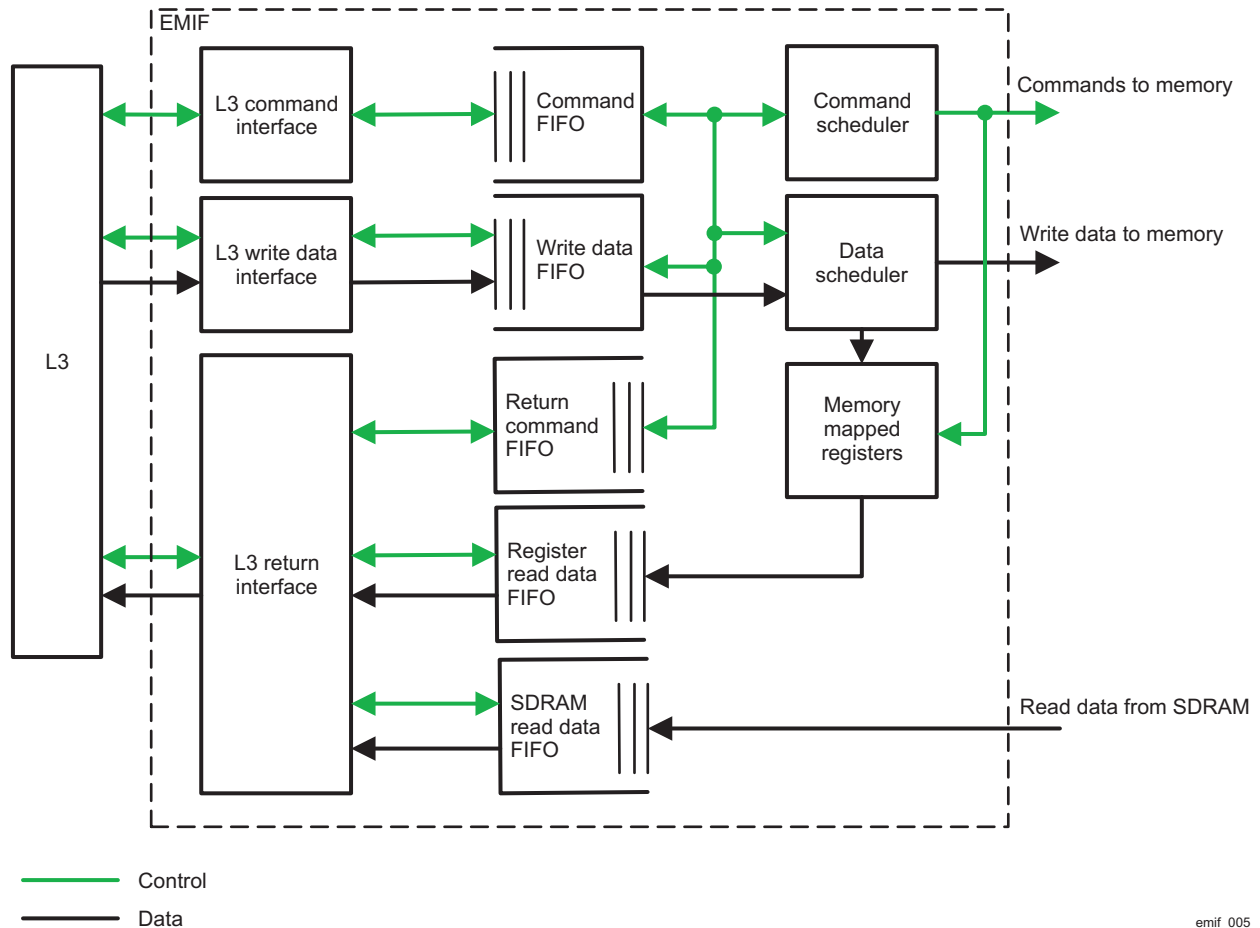

15.3.4.1.2 FIFOs Description

EMIF contains the following FIFOs:

- Command FIFO
- Write Data FIFO
- Return Command FIFO
- Two Read Data FIFOs

Figure 15-49 shows the overall architecture of the EMIF module.

Figure 15-49. FIFO Block Diagram

The System (128-bit) L3 interface being the main interface has higher allocation of FIFO slots than the Low-latency (64-bit) L3 interface. The entries allocation is shown in [Table 15-98](#).

Table 15-98. FIFO Allocation

| Parameter | System L3-Interface entries | Low-Latency L3-Interface entries |
|-------------------------|-----------------------------|----------------------------------|
| Command FIFO | Programmable ⁽¹⁾ | Programmable ⁽¹⁾ |
| Write Data FIFO | 20 | 5 |
| Return Command FIFO | 22 | 17 |
| SDRAM Read Data FIFO | 22 | 17 |
| Register read Data FIFO | 2 | 2 |

⁽¹⁾ The total number of entries in the command FIFO is 10.

The command FIFO is shared between the two L3 interfaces, whereas there are two different FIFOs for each other type, one dedicated to each L3 interface.

The Command FIFO stores all the commands coming in on the L3 command interface. The allocation of entries in the Command FIFO is programmable per L3 interface using the [EMIF_L3_CONFIG\[27:24\]REG_SYS_THRESH_MAX](#) and [EMIF_L3_CONFIG\[19:16\]REG_LL_THRESH_MAX](#) bit fields.

If the addition of the [EMIF_L3_CONFIG\[27:24\]REG_SYS_THRESH_MAX](#) and [EMIF_L3_CONFIG\[19:16\]REG_LL_THRESH_MAX](#) fields is greater than the number of entries in the Command FIFO, the allocation would depend on the traffic on the interfaces. For example, if both the fields are programmed to 7, then either of the interfaces can use 7 entries in the Command FIFO if the other interface is idle. If both the interfaces have traffic, then the EMIF would start gradually allocating entries to both interfaces until it settles down to 7 entries for the low-latency interface and 3 for system interface since the low-latency interface has higher priority. If low-latency interface has no traffic, the system interface can use 7 entries.

The allocation would also depend on the traffic on the interfaces, if the [EMIF_L3_CONFIG\[27:24\]REG_SYS_THRESH_MAX](#) and [EMIF_L3_CONFIG\[19:16\]REG_LL_THRESH_MAX](#) fields are both programmed to be equal to or greater than the number of entries in the Command FIFO. For example, if both the fields are programmed to 10, then the low-latency port can use all the entries if there is no traffic on the system interface. However, if there is no traffic on the low-latency interface, the system interface can use all but one entry. This is because the low-latency interface has higher priority than the system interface. The only way for the system interface to use all command FIFO entries is to set the [EMIF_L3_CONFIG\[19:16\]REG_LL_THRESH_MAX](#) to zero. Writing a zero will reserve no space for the associated interface. In the event the value is set to zero and a request is seen for that interface, the command FIFO will assume a value of 1 for that interface.

The Write Data FIFO stores the write data for all the write transactions coming in on the L3 write data interface (when the Write Data FIFO is not full).

The Return Command FIFO stores all the return transactions that are to be issued to the L3 return interface. These include the write status return and the read data return commands.

There are two Read Data FIFOs that store the read data to be sent to the L3 return interface. One Read Data FIFO stores read data from the memory mapped registers. The other Read Data FIFO stores read data from external memory.

A write command is executed only when four L3 words of the corresponding data is received in the Write Data FIFO, or when it is the last data, and if there is space in the Return Command FIFO. The EMIF will schedule a read only if the results can fit into both the Return Command FIFO and the corresponding Read Data FIFOs.

15.3.4.1.3 Arbitration

The EMIF looks at all the commands stored in the Command FIFO to schedule commands to the external memory. All commands with the same MConnID on a particular L3 interface will complete in order. The EMIF does not guarantee ordering between commands with different MConnID or between commands from two L3 interfaces. For more information about L3 interconnect terms (MConnID, MCMD, MADDR, ...) see [Section 13.2, L3 Interconnect](#)

However, the EMIF will maintain data coherency. Therefore, the EMIF will block a command, regardless of priority or L3 interface, if that command is to the same block address (2048 bytes) as an older command which has not completed.

Thus, the EMIF might have one pending read or write for each MConnID. Among all pending reads, the EMIF selects all reads that have their corresponding SDRAM banks already open. Similarly, among all pending writes, the EMIF selects all writes that have their corresponding SDRAM banks already open. Accesses to memory mapped registers are treated as accesses that have open banks.

As a result of the above reordering, the EMIF might now have several pending reads and writes that have their corresponding banks open. The EMIF then selects the highest priority read from pending reads, and the highest priority write from pending writes. Commands from the low-latency L3 interface have higher priority over the commands from the system L3 interface. If two or more commands have the highest priority, the EMIF selects the oldest command. As a result, the EMIF might now have the next read and a write command. If the Return Command FIFO and the Read Data FIFO has space and the external bus conflict is resolved, the EMIF performs the final read command before the final write command. If the Return Command FIFO has space but the Read Data FIFO is full, the EMIF performs the final write command before the final read command.

Resolution of external bus conflict means all the SDRAM command to command counters are satisfied and the read to write or write to read turn around time is met.

The EMIF does not support tag interleaving. In other words, for a L3 interface, the EMIF completes executing a L3 command before it switches to another command. The EMIF can however interleave execution between commands from two L3 interfaces.

The data coherency inside the EMIF is only guaranteed in a single level of L3 infrastructure. For example, if a write from a secondary L3 bus segment is blocked by a bridge element, the read from a tertiary bus can still beat the write to the EMIF. In such a case, in order to confirm that a write from master A has landed before a read from master B is performed, master A must wait for the write status from the EMIF before indicating to master B that the data is ready to be read. If master A does not use the L3 wait status, it must perform the following sequence of operations:

1. Perform the required write
2. Perform a dummy write to the [EMIF_MOD_ID_REV](#) register
3. Perform a dummy read to the [EMIF_MOD_ID_REV](#) register
4. Indicate to the master B that the data is ready to be read after completion of read in step 3. The completion of read in step 3 ensures that the previous writes were done

Apart from reads and writes the EMIF also needs to open and close SDRAM banks, and maintain the refresh counts for a SDRAM. The priority of SDRAM commands with respect to refresh levels are as follows:

1. SDRAM Refresh request when Refresh-Must level is reached (highest priority)
2. L3 request for a read without a higher priority write
3. SDRAM Refresh request when Refresh-Need level is reached
4. L3 request for a write
5. SDRAM Activate commands
6. SDRAM Deactivate commands
7. SDRAM Deep Power-Down request
8. SDRAM Refresh request when Refresh-May level is reached
9. SDRAM Self-refresh or SDRAM Power-Down request (lowest priority).

While performing the above listed scheduling algorithm, the EMIF might run into following two conditions:

1. A continuous stream of high priority commands can block lower priority commands
2. A continuous stream of SDRAM commands to a row in an open bank can block commands to another row in the same bank

To avoid a continuous blocking effect, the EMIF momentarily raises the priority of the oldest command over all other commands when the number of memory accesses equals to the value programmed in the [EMIF_L3_CONFIG\[7:0\] REG_PR_OLD_COUNT](#) field.

On top of the above scheduling, the highest priority condition is a reset command. If this condition occurs, the EMIF abandons whatever it is currently doing and begins its start-up sequence. In this case, commands and data stored in the FIFOs are lost. The EMIF also starts its start-up sequence whenever the [EMIF_SDRAM_CONFIG](#) is written and [EMIF_SDRAM_REF_CTRL\[31\] REG_INITREF_DIS](#) is set to 0. In this case, commands and data stored in the FIFOs are not lost. The EMIF will ensure that in-flight read or write transactions to the SDRAM are complete before starting the initialization sequence.

All the accesses to a SDRAM are pipelined to maximize the external bus utilization. All of these are done while fulfilling the access timing requirements of a SDRAM.

15.3.4.2 Clock Management

The EMIF can gate off the EMIF_FCLK. There is an internal mechanism which can stop the EMIF_FCLK automatically.

EMIF_FCLK can only be stopped after the SDRAM is put into Self Refresh Mode and the power-idle protocol on the L3 bus is complete.

The EMIF waits for the DLL lock before performing any memory access.

The EMIF_FCLK frequency can be changed only after putting the external SDRAM in self-refresh mode.

EMIF_i_FCLK frequency is equal to half of the DDR_PHY_CLK frequency. DDR_PHY_CLK is equal to half of the PHY_ROOT_CLK frequency.

15.3.4.3 Software Reset

EMIF does not support a software reset.

EMIF supports the global warm reset mode during which the EMIF keeps the the SDRAM content. Upon a request from the PRCM module indicating a need to enter global warm reset mode, the EMIF executes the following:

- Completes the on-going access and then puts the SDRAM in self-refresh mode
- Clears all its FIFO contents and deasserts sys_SCmdAccept and sys_SDataAccept ports

When the global warm reset must terminate:

- The PRCM block deasserts its request signal to the EMIF.
- EMIF exits Self Refresh state once it receives host accesses from the MPU to the external memory.

15.3.4.4 System Power Management

15.3.4.4.1 Read Idle Window

The [EMIF_READ_IDLE_CTRL](#) register allows the ability to force idle time between consecutive reads to allow the DDR PHY to recalibrate the DLL delays during gradual voltage and frequency change.

The [EMIF_READ_IDLE_CTRL](#)[8:0] REG_READ_IDLE_INTERVAL field determines the maximum interval ((REG_READ_IDLE_INTERVAL - 1) * 64 EMIF_FCLK clock cycles) between read idle detections or force read idle time. A value of 0 disables the read idle function.

The [EMIF_READ_IDLE_CTRL](#)[19:16] REG_READ_IDLE_LEN bit field determines the minimum size of idle window for the read idle detection as well as the force read idle time. The EMIF only introduces idle time if it does not see at least REG_READ_IDLE_LEN - 1 number of idle EMIF_FCLK cycles in REG_READ_IDLE_INTERVAL. Any command other than a read command is considered idle for this purpose. Force read idle occurs when the data bus is busy transferring read data and the read idle interval expires.

15.3.4.4.2 LPDDR2-SDRAM Power-Down Mode

The EMIF supports power-down mode for low power. The EMIF automatically puts the SDRAM into power-down after the EMIF is idle for [EMIF_PWR_MGMT_CTRL](#)[15:12] REG_PD_TIM number of EMIF_FCLK cycles and the [EMIF_PWR_MGMT_CTRL](#)[10:8] REG_LP_MODE field is set to 0x4. In power-down mode, the EMIF does not stop the clocks to the SDRAM. The EMIF maintains $lpddr2i_cke[j][1:0]$ ($i = 1$ or 2 and $j = 0$ or 1) low to maintain the power-down state.

When the SDRAM is in power-down, the EMIF services register accesses as normal. The EMIF also services LPDDR2-NVM accesses as normal provided when it is not in power-down (in the case of the SDRAM memories are connected to the same EMIF through two different chip-selects).

If the the LPDDR2-SDRAM is in power-down mode and:

1. [EMIF_PWR_MGMT_CTRL](#)[10:8] REG_LP_MODE field is changed from 0x4 to some other value or
 2. A SDRAM access is requested or
 3. The Refresh Must level is reached
- then the EMIF will bring the SDRAM out of power-down mode.

For LPDDR2-SDRAM, the EMIF module:

1. Drives $lpddr2i_cke[j][1:0]$ ($i = 1$ or 2 and $j = 0$ or 1) high
2. Waits for [EMIF_SDRAM_TIM_2](#)[30:28] REG_T_XP + 1 cycles
3. Enters its idle state and can issue any commands.

15.3.4.4.3 LPDDR2-SDRAM Deep Power-Down Mode

For ultimate power savings, the EMIF supports deep power-down mode for LPDDR2-SDRAM.

The SDRAM can be forced into deep power-down state through software by setting the [EMIF_PWR_MGMT_CTRL\[11\] REG_DPD_EN](#) field to 0x1. In this case, the EMIF continues normal operation until all SDRAM memory access requests are serviced. At this point the EMIF issues a DEEP POWER-DOWN command. The EMIF then maintains [lpddr2i_cke\[j\]\[1:0\]](#) ($i = 1$ or 2 and $j = 0$ or 1) low to maintain the deep power-down state. In deep power-down mode, the EMIF automatically stops the clocks to the SDRAM.

Setting the [EMIF_PWR_MGMT_CTRL\[11\] REG_DPD_EN](#) bit to 1 overrides the setting of [EMIF_PWR_MGMT_CTRL\[10:8\] REG_LP_MODE](#) bit field. Therefore, if the SDRAM is in self refresh or power-down mode, and [EMIF_PWR_MGMT_CTRL\[11\] REG_DPD_EN](#) bit is set to 1, the EMIF exits those modes and go into deep power-down mode.

When the SDRAM is in deep power-down, the EMIF services register accesses as normal. The EMIF also services LPDDR2-NVM accesses as normal provided it is not in power-down (in the case of a SDRAM and a NVM memories are connected to the same EMIF through two different chip-selects).

If the [EMIF_PWR_MGMT_CTRL\[11\] REG_DPD_EN](#) bit is set to 0x0, the EMIF brings the SDRAM out of deep power-down state.

For LPDDR2-SDRAM, the EMIF controller:

1. Drives [lpddr2i_cke\[j\]\[1:0\]](#) ($i = 1$ or 2 and $j = 0$ or 1) high
2. Issues a RESET command to LPDDR2 (MRW)
3. Enters its IDLE state and can issue any commands.
4. Software must perform initialization as specified in the LPDDR2 Initialization section, see [Section 15.3.4.13](#)

15.3.4.4.4 LPDDR2-NVM Power-Down Mode

The EMIF supports power-down mode for LPDDR2-NVM. The EMIF automatically puts the LPDDR2-NVM into power-down after the EMIF is idle for [EMIF_PWR_MGMT_CTRL\[15:12\] REG_PD_TIM](#) number of EMIF_FCLK cycles and the [EMIF_PWR_MGMT_CTRL\[10:8\] REG_LP_MODE](#) bit field is set to 0x4. The EMIF will maintain [lpddr2i_cke\[j\]\[1:0\]](#) ($i = 1$ or 2 and $j = 0$ or 1) low to maintain the power-down state.

When LPDDR2-NVM is in power-down, the EMIF services register accesses as normal. The EMIF also services SDRAM accesses as normally, provided it is not in self-refresh or power-down (in the case of the NVM memories are connected to the same EMIF through two different chip-selects).

When the LPDDR2-NVM is in power-down mode and:

1. [EMIF_PWR_MGMT_CTRL\[10:8\] REG_LP_MODE](#) field is changed from 0x4 to some other value or
2. A LPDDR2-NVM access is requested or then the EMIF brings the LPDDR2-NVM out of power-down mode.

For LPDDR2-NVM, the EMIF module:

1. Drives [lpddr2i_cke\[j\]\[1:0\]](#) ($i = 1$ or 2 and $j = 0$ or 1) high
2. Waits for [EMIF_SDRAM_TIM_2\[30:28\] REG_T_XP + 1](#) cycles
3. Enters its IDLE state and can issue any commands

15.3.4.4.5 LPDDR2-SDRAM Self-Refresh Mode

The EMIF supports self-refresh mode for low power. The EMIF automatically puts the SDRAM into self-refresh after the EMIF is idle for [EMIF_PWR_MGMT_CTRL\[3:0\] REG_CS_TIM](#) number of EMIF_FCLK cycles and the [EMIF_PWR_MGMT_CTRL\[10:8\] REG_LP_MODE](#) bit field is set to 0x2. In self-refresh mode, the EMIF automatically stops the clocks to the SDRAM. The EMIF maintains [lpddr2i_cke\[j\]\[1:0\]](#) ($i = 1$ or 2 and $j = 0$ or 1) low to maintain the self-refresh state.

When the SDRAM is in self-refresh, the EMIF services register accesses as normal. The EMIF also services LPDDR2-NVM accesses as normal provided it is not in power-down (in the case of a SDRAM and a NVM memories are connected to the same EMIF through two different chip-selects).

If the LPDDR2-SDRAM is in self refresh mode and:

1. [EMIF_PWR_MGMT_CTRL](#)[10:8] REG_LP_MODE bit field is changed from 0x2 to some other value or
2. A SDRAM access is requested or
3. [EMIF_SDRAM_TIM_2](#)[2:0] REG_T_CKE + 1 cycles have elapsed since the SELF-REFRESH command was issued

then the EMIF brings the SDRAM out of self-refresh mode.

For LPDDR2-SDRAM, the EMIF:

1. Enables clocks
2. Drives [lpddr2i_cke](#)[1:0] (i = 1 or 2 and j =0 or 1) high
3. Waits for [EMIF_SDRAM_TIM_2](#)[24:16] REG_T_XSNR + 1 cycles
4. Starts an auto-refresh cycle in the next cycle
5. Enters its IDLE state and can issue any commands

15.3.4.4.6 Save and Restore

The EMIF supports save and restore mechanism to completely switch off power to the EMIF.

See [Chapter 3, Power, Reset, and Clock Management](#) of the device for more information on *off-mode sequence* and *restore power to the EMIF sequence* of operations.

15.3.4.4.7 Retention Mode

EMIF supports full-retention mode.

15.3.4.5 Interrupt Requests

The EMIF sources two interrupts: one for the System L3 interface and the other for the Low-latency L3 interface. The pulse and level interrupt signals for a particular interface are both sourced from the same raw interrupt internal to the module.

The EMIF will set the [EMIF_IRQSTATUS_RAW_SYS](#)[0] REG_RAW_SYS / [EMIF_IRQSTATUS_RAW_LL](#)[0] REG_RAW_LL bit (depending on which interface sent the errored command) to 1, if an access request to an unsupported MAddrSpace is received. If such an error occurs, it is due to a bad programming of the DMM. See [Section 15.2, Dynamic Memory Manager](#) for more information on addressing.

The interrupts can be cleared once serviced by writing a 1 to the corresponding bits either in the [EMIF_IRQSTATUS_RAW_SYS](#) / [EMIF_IRQSTATUS_RAW_LL](#) or [EMIF_IRQSTATUS_SYS](#) / [EMIF_IRQSTATUS_LL](#) registers.

[Table 15-99](#) lists the event flags, and their mask, that can cause module interrupts.

Table 15-99. Events

| Event Flag | Event Mask | Description |
|-------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------|
| EMIF_IRQSTATUS_RAW_SYS [1] REG_TA_SYS / EMIF_IRQSTATUS_SYS [1] REG_TA_SYS | EMIF_IRQENABLE_SET_SYS [1] REG_EN_TA_SYS / EMIF_IRQENABLE_CLR_SYS [1] REG_EN_TA_SYS | System L3 interrupt for SDRAM temperature alert. |
| EMIF_IRQSTATUS_RAW_LL [1] REG_TA_LL / EMIF_IRQSTATUS_LL [1] REG_TA_LL | EMIF_IRQENABLE_SET_LL [1] REG_EN_TA_LL / EMIF_IRQENABLE_CLR_LL [1] REG_EN_TA_LL | Low-latency L3 interrupt for SDRAM temperature alert. |
| EMIF_IRQSTATUS_RAW_SYS [0] REG_ERR_SYS / EMIF_IRQSTATUS_SYS [0] REG_ERR_SYS | EMIF_IRQENABLE_SET_SYS [0] REG_EN_ERR_SYS / EMIF_IRQENABLE_CLR_SYS [0] REG_EN_ERR_SYS | System L3 interrupt for command or address error. |
| EMIF_IRQSTATUS_RAW_LL [0] REG_ERR_LL / EMIF_IRQSTATUS_LL [0] REG_ERR_LL | EMIF_IRQENABLE_SET_LL [0] REG_EN_ERR_LL / EMIF_IRQENABLE_CLR_LL [0] REG_EN_ERR_LL | Low-latency L3 interrupt for command or address error. |

15.3.4.6 SDRAM Output Impedance Calibration

The EMIF supports automatic output impedance calibration. The ZQ calibration can be enabled per chip-select by setting [EMIF_ZQ_CONFIG\[31\] REG_ZQ_CS1EN](#) and [EMIF_ZQ_CONFIG\[30\] REG_ZQ_CS0EN](#) bits. The EMIF supports following three types of ZQ calibration commands:

- ZQINIT - ZQ calibration command during initialization
- ZQCS - ZQ calibration short command
- ZQCL - ZQ calibration long command

The EMIF periodically issues a ZQCS command every time [EMIF_ZQ_CONFIG\[15:0\] REG_ZQ_REFINTERVAL](#) expires. In other words, the [REG_ZQ_REFINTERVAL](#) defines the interval between ZQCS commands. The EMIF will wait and block any other command for ([EMIF_SDRAM_TIM_3\[20:15\] REG_ZQ_ZQCS+1](#)) number of clock DDR clock cycles every time a ZQCS command is issued.

If [EMIF_ZQ_CONFIG\[28\] REG_ZQ_SFEXITEN](#) field is set to a 1, the EMIF will issue a ZQCL command every time it exits Self-Refresh, Active Power-Down, and Precharge Power-Down. The EMIF will wait and block any other command for ([EMIF_ZQ_CONFIG\[17:16\] REG_ZQ_ZQCL_MULT+1](#))*([EMIF_SDRAM_TIM_3\[20:15\] REG_ZQ_ZQCS+1](#)) number of clock DDR clock cycles every time a ZQCL command is issued.

If a separate calibration resistor is used per device, the ZQ calibration can be preformed simultaneously over both the chip-selects. To enable ZQ calibration to be performed simultaneously over both chip-selects, the [EMIF_ZQ_CONFIG\[27\] REG_ZQ_DUALCALEN](#) filed must be set to a 1. If [REG_ZQ_DUALCALEN](#) is set to a 0, the EMIF will perform ZQ calibration per chip-select serially.

15.3.4.7 SDRAM Temperature Monitoring

The EMIF supports automatic temperature monitoring to facilitate the software to update the refresh rate according to the LPDDR2 device temperature changes. The temperature monitoring can be enabled per chip-select by setting [EMIF_TEMP_ALERT_CONFIG\[31\] REG_TA_CS1EN](#) and [EMIF_TEMP_ALERT_CONFIG\[30\] REG_TA_CS0EN](#) bits.

The EMIF periodically polls the temperature of LPDDR2 (issues a MRR command to Mode Register 4) every time [EMIF_TEMP_ALERT_CONFIG\[21:0\] REG_TA_REFINTERVAL](#) expires. In other words, the [REG_TA_REFINTERVAL](#) defines the interval between temperature alert polls. If the EMIF sees a 1 on bit 7 of the read data value from MRR, indicating that the temperature has changed, the [EMIF_IRQSTATUS_SYS\[1\] REG_TA_SYS](#) bit (for L3 interconnect), respectively, the [EMIF_IRQSTATUS_LL\[1\] REG_TA_LL](#) bit for the Low-Latency L3 connected LPDDR2-NVM is set and the module sends an interrupt both on the system and low-latency interrupt lines. On receipt of the interrupt, the software will update the [EMIF_SDRAM_REF_CTRL\[15:0\] REG_REFRESH_RATE](#) field to the required value as per the temperature change.

If [EMIF_TEMP_ALERT_CONFIG\[28\] REG_TA_SFEXITEN](#) field is set to a 1, the EMIF will poll for temperature change every time it exits Self-Refresh, Active Power-Down, and Precharge Power-Down.

Since the EMIF is performing a MRR, it needs information on how the LPDDR2 are connected. The [EMIF_TEMP_ALERT_CONFIG\[27:26\] REG_TA_DEVWDT](#) and [EMIF_TEMP_ALERT_CONFIG\[25:24\] REG_TA_DEVCNT](#) bits provides the necessary information to the EMIF for MRR data compare. For example, if [REG_TA_DEVWDT](#) is set to 0 indicating 8-bit devices used, and if [REG_TA_DEVCNT](#) is set to 2 indicating four devices used to form a 32-bit bus, the mask used for checking would be 4'b1111, that is, the EMIF would expect data on each of the byte lanes on a 32-bit bus.

15.3.4.8 SDRAM Refresh Scheduling

The EMIF uses two counters to schedule AUTO REFRESH commands: a 13-bit decrementing **refresh interval counter** and a 4-bit refresh **backlog counter**. The *interval counter* is used to define the rate at which connected SDRAM devices will be refreshed. It is loaded with the [EMIF_SDRAM_REF_CTRL\[15:0\] REG_REFRESH_RATE](#) field value at reset (only the 13 LSb bits are taken). The interval counter decrements by one each cycle until it reaches zero at which point it reloads from [EMIF_SDRAM_REF_CTRL\[15:0\] REG_REFRESH_RATE](#) and restarts decrementing. The counter also reloads and restarts decrementing whenever the [EMIF_SDRAM_REF_CTRL\[15:0\] REG_REFRESH_RATE](#) field is updated.

The refresh *backlog counter* records the number of AUTO REFRESH commands the EMIF currently has outstanding. The backlog counter increments by one each time the interval counter reloads (unless it has reached its maximum value of 15). The backlog counter decrements by one each time the EMIF issues an AUTO REFRESH command (unless it is already at zero). For the range of values that the backlog counter can take, there are four levels of urgency with which the EMIF should perform an auto refresh cycle (in which it issues AUTO REFRESH commands), as follows:

- Refresh May level is reached whenever the backlog count is greater than 0, to indicate that there is a refresh backlog, so if the EMIF is not busy and none of the SDRAM banks are open, it should perform an auto refresh cycle.
- Refresh Release level is reached whenever the backlog count is greater than 4, to indicate that the refresh backlog is getting high, so if the EMIF is not busy it should perform an auto refresh cycle even if any banks are open.
- Refresh Need level is reached whenever the backlog count is greater than 5, to indicate that the refresh backlog is getting high and the EMIF should raise the priority of performing an auto refresh cycle above that of servicing new memory write requests. The EMIF starts servicing new memory accesses after Refresh Release level is cleared.
- Refresh Must level is reached whenever the backlog count is greater than 7, to indicate that the refresh backlog is getting excessive and the EMIF should perform an auto refresh cycle before servicing any new memory access requests. The EMIF starts servicing new memory accesses after Refresh Release level is cleared.

The refresh counters do not operate when SDRAM has been put into self-refresh mode.

The EMIF issues AUTO REFRESH commands within auto refresh cycles. An auto refresh cycle consists of issuing an AUTO REFRESH command and waiting T_{RFC} (refer to the SDRAM Timing 3 register, [EMIF_SDRAM_TIM_3](#)) cycles before rechecking the refresh levels. If the Refresh Release level is not reached, the EMIF starts another auto refresh cycle, otherwise it returns to the idle state where it can issue any command. The EMIF ensures that no more than eight AUTO REFRESH commands are issued in any rolling $tREFBW (= 4 * 8 * tRFC)$ window.

15.3.4.8.1 Performance Counters Description

The [EMIF_PERF_CNT_1](#) and [EMIF_PERF_CNT_2](#) registers can be used to monitor or calculate the EMIF bandwidth and efficiency. These counters can count events such as total SDRAM accesses, SDRAM activates, reads, writes, etc. Each counter counts events independent of the other counters. In addition to the ability to count events, the counters can also filter the events from a particular master or address space. The events to be counted and the filter enabling can be configured using the [EMIF_PERF_CNT_CFG](#) register. The filter value to be used can be configured using the [EMIF_PERF_CNT_SEL](#) register. Each counter can be configured independently.

[Table 15-100](#) shows all the events that can be counted and whether a filter can be applied to a particular event. A filter can be applied to an event if the following bits in the Performance Counter 1 or Performance Counter 2 register can be set equal to 0x1 for that particular event:

- Performance Counter 1 register: [EMIF_PERF_CNT_CFG](#)[15] [REG_CNTR1_MCONNID_EN](#) and [EMIF_PERF_CNT_CFG](#)[14] [REG_CNTR1_REGION_EN](#)
- Performance Counter 2 register: [EMIF_PERF_CNT_CFG](#)[31] [REG_CNTR2_MCONNID_EN](#) and [EMIF_PERF_CNT_CFG](#)[30] [REG_CNTR2_REGION_EN](#)

[Table 15-100](#) shows the possible filter configurations for the two performance counters. These filter configurations can be used in conjunction with a L3 master ID and/or external chip-select to obtain performance statistics for a particular L3 master and/or external chip-select.

Table 15-100. Performance Counter Filter Configuration

| CNTRn_CFG ⁽¹⁾ | CNTRn_REGION_EN ⁽¹⁾ | CNTRn_MCONNID_EN ⁽¹⁾ | Description |
|------------------------------------------|------------------------------------------------|-------------------------------------------------|----------------------------|
| 0x0 ⁽²⁾ | 0x0 | 0x0 or 0x1 | Count total SDRAM accesses |

⁽¹⁾ n = 1 or 2

⁽²⁾ When MReqDebug is set to a 1 for a particular L3 command, the performance counters will not be incremented for that command.

Table 15-100. Performance Counter Filter Configuration (continued)

| CNTRn_CFG ⁽¹⁾ | CNTRn_REGION_EN ⁽¹⁾ | CNTRn_MCONNID_EN ⁽¹⁾ | Description |
|--------------------------|--------------------------------|---------------------------------|---------------------------------------------------------------------------------------------|
| 0x1 ⁽²⁾ | 0x0 | 0x0 or 0x1 | Count total SDRAM activates |
| 0x2 ⁽²⁾ | 0x0 or 0x1 | 0x0 or 0x1 | Count total L3 reads. CPU cache based operations are 32 bytes. DMA burst is 128 bytes. |
| 0x3 ⁽²⁾ | 0x0 or 0x1 | 0x0 or 0x1 | Count total L3 writes. CPU cache based operations are 32 bytes. DMA burst is 128 bytes. |
| 0x4 | 0x0 | 0x0 | Count number of EMIF FCLK clock cycles L3 Command FIFO is full |
| 0x5 | 0x0 | 0x0 | Count number of EMIF FCLK clock cycles L3 Write Data FIFO is full |
| 0x6 | 0x0 | 0x0 | Count number of EMIF FCLK clock cycles L3 Read Data FIFO is full |
| 0x7 | 0x0 | 0x0 | Count number of EMIF FCLK clock cycles L3 Return Command FIFO is full |
| 0x8 | 0x0 or 0x1 | 0x0 or 0x1 | Count number of priority elevations |
| 0x9 | 0x0 | 0x0 | Count number of EMIF FCLK clock cycles that a command was pending |
| 0xA ⁽³⁾ | 0x0 | 0x0 | Count number of EMIF FCLK clock cycles for which the memory data bus was transferring data. |
| 0xA ⁽³⁾ | 0x0 | 0x1 | Count number of L3 commands for which the memory data bus was transferring data. |
| 0xB to 0xF | 0x0 | 0x0 | Reserved for future use. |

⁽³⁾ When MReqDebug is set to a 1 for a particular L3 command, the performance counters will not be incremented for that command.

When CNTRn_CFG = 0xA and CNTRn_MCONNID_EN=0x1, the following guidelines must apply:

- Count of 1 implies OCP command up to 32 bytes for all the initiators except for Cortex-A9 MPU
- Count of 1 implies OCP command up to 16 bytes for Cortex-A9 MPU when all the other initiators are not generating traffic on SDRAM.
- When ConnID is set to a value other than 0x00, the performance counter reflects the traffic generated by the initiator associated with that ConnID. In case of ConnID=0x00 (MPU), the performance counter reflects combined traffic by all active initiators. Therefore, if there are multiple initiators generating traffic, the traffic generated by MPU must be calculated using the formula:

$$\text{Actual MPU Count} = \text{Count value} - \sum_{i=0}^{\text{all_initiators-MPU}} \text{Count}_i$$

where i is different initiators and Count_i is the Count value for each of those initiators. Then:

- Actual MPU count of 1 implies OCP command up to 16 bytes for Cortex-A9 MPU
- Bandwidth for all other initiators except MPU is Count × 32 bytes
- Bandwidth calculation for MPU is MPU Count × 16 bytes

15.3.4.8.2 Performance Counters General Examples

15.3.4.8.2.1 PERF_CNT_1 General Example for Counting Write Accesses

The Performance Counter 1 register needs to count all write accesses from the dual Cortex-M3 MPU subsystem:

- To enable counting writes, the [EMIF_PERF_CNT_CFG\[3:0\]](#) REG_CNTR1_CFG bit field must be set to 0x3.
- The [EMIF_PERF_CNT_SEL\[15:8\]](#) REG_MCONNID1 bit field must be set to 0x44. The values

programmed into the REG_MCONNIDx bit fields are those listed in [Table 28-20, ConnID Mapping \(Debug View\)](#), in [Chapter 28, On-Chip Debug Support](#), left-shifted by 2 bits.

- To enable filtering, the [EMIF_PERF_CNT_CFG\[15\]](#) REG_CNTR1_MCONNID_EN bit must be set to 0x1.

With this configuration, Counter 1 counts every write made to the EMIF from master 0x44 to any address space. This does not include accesses from other masters, or commands other than writes.

15.3.4.8.2.2 *PERF_CNT_2 General Example for Counting Total Access*

The Performance Counter 2 register needs to count total accesses to SDRAM regardless of the masters or address space.

- To enable counting all SDRAM accesses, the [EMIF_PERF_CNT_CFG\[19:16\]](#) REG_CNTR2_CFG bit field must be set to 0x0.
- To disable filtering, the [EMIF_PERF_CNT_CFG\[31\]](#) REG_CNTR2_MCONNID_EN and [EMIF_PERF_CNT_CFG\[30\]](#) REG_CNTR2_REGION_EN bits must be set to 0x0.

With this configuration, Counter 2 counts every access made to the EMIF. This includes all accesses from all masters and to any address space.

15.3.4.8.2.3 *PERF_CNT_3 General Example for Counting all Read Accesses*

The Performance Counter 1 register needs to count all read accesses from the dual Cortex-M3 MPU subsystem to address space 0x0.

- To enable counting reads, the [EMIF_PERF_CNT_CFG\[3:0\]](#) REG_CNTR1_CFG bit field must be set to 0x2.
- The [EMIF_PERF_CNT_SEL\[15:8\]](#) REG_MCONNID1 and [EMIF_PERF_CNT_SEL\[1:0\]](#) REG_REGION_SEL1 bit fields must be set to 0x44 and 0x0, respectively.
- To enable filtering, the [EMIF_PERF_CNT_CFG\[15\]](#) REG_CNTR1_MCONNID_EN and [EMIF_PERF_CNT_CFG\[14\]](#) REG_CNTR1_REGION_EN bits must be set to 0x1.

With this configuration, Counter 1 counts every read made to the EMIF from master 0x44 to address space 0x0. This does not include accesses from other masters or accesses to other address space and does not include commands other than reads.

15.3.4.9 *EMIF Access Cycles*

By default the EMIF keeps SDRAM chip-selects active. To direct a command to just one of the SDRAMs it deasserts the chip-select to the other SDRAM for the duration of the command. If [EMIF_SDRAM_CONFIG\[3\]](#) REG_EBANK field in the SDRAM Config register is set to 0, chip-select 1 is always driven high except during initialization and for refresh, power down, self refresh, and deep power down commands.

The EMIF always performs burst accesses to SDRAM. Multiple SDRAM bursts may be needed to service a single L3 burst request. [Table 15-104](#) to [Table 15-105](#) show a few examples on how EMIF accesses SDRAM for a linear incrementing transaction type. T0, T1, etc. are clock cycles. R0 is read starting at column 0, R8 is read starting at column 8, and R16 is read starting at column 16. D0-1 is the data from column 0 and 1, D2-3 is the data from column 2 and 3, and so on.

Table 15-101. 64-Byte Linear Read Starting at Address 0x0

| | | | | D4-5 | D6-7 | D8-9 | D10-11 | D12-13 | D14-15 | D16-17 | D18-19 | Unused | Unused |

Table 15-105. 64-Byte Linear Read Starting at Address 0x18

| T0 | T1 | T2 | T3 | T4 | T5 | T6 | T7 | T8 | T9 | T10 | T11 | T12 | T13 |
|----|----|----|----|------|--------|------|--------|--------|--------|--------|--------|--------|--------|
| R6 | | R8 | | | | | R16 | | | | | | |
| | | | | D6-7 | Unused | D8-9 | D10-11 | D12-13 | D14-15 | D16-17 | D18-19 | D20-21 | Unused |

EMIF will use the unused data phases in the above figure by issuing successive read commands if there are reads to open banks pending in the command FIFO.

The write data conversion from single data rate to double data rate is done outside the EMIF.

15.3.4.9.1 SDRAM Read

A read access to a SDRAM is initiated with a READ command. The EMIF provides the internal bank address and the column address on pad_ca_o with the READ command. The EMIF registers the first read data from lpddr2i_dj (i = 1 or 2 and j = 0 or 1) after (read_latency + 3) DDR clock cycles. Read latency is programmed in the PHY Control 1 register, [EMIF_DDR_PHY_CTRL_1](#).

15.3.4.9.2 SDRAM Write

A write access to a SDRAM is initiated with a WRITE command. The EMIF provides the internal bank address and the column address on pad_ca_o with the WRITE command.

EMIF delays the write data by the appropriate write latency minus one. Subsequent data words are provided on lpddr2i_dj (i = 1 or 2 and j = 0 or 1) along with the appropriate data mask on lpddr2i_dmj (i = 1 or 2 and j = 0 or 1) on each successive clock cycles. The DDR PHY then adds one more clock cycle delay to the write data to appropriately center the write data to the outgoing DQS.

15.3.4.10 Turn Around Time

[Table 15-106](#) shows the turn around time that the EMIF introduces on the data bus for various back-to-back accesses. The EMIF takes advantage of the CAS latencies and packs the commands as close as possible on the control bus to introduce the following turn around time on the data bus.

Table 15-106. Turn Around Time

| Previous Access | Next Access | Turn Around Time (number of DDR clock cycles) |
|-----------------|--------------------------------|-----------------------------------------------|
| SDRAM read | SDRAM read to same chip-select | 0 |

Table 15-106. Turn Around Time (continued)

| Previous Access | Next Access | Turn Around Time (number of DDR clock cycles) |
|-----------------|-------------------------------------|-----------------------------------------------|
| SDRAM read | SDRAM read to different chip-select | 2 |
| SDRAM read | SDRAM write | 2 |
| SDRAM write | SDRAM write | 0 |
| SDRAM write | SDRAM read | 2 |

15.3.4.11 SDRAM Address Mapping

The EMIF interleaves the internal banks for SDRAM connected to both the chip-selects (see [Table 15-107](#) for the SDRAM addressing space), according to the DMM (see [Section 15.2, Dynamic Memory Manager](#) for more information). From the system point of view, the external SDRAM is seen as one block of SDRAM. If two external 64-MB devices are used, a 128-MB memory block is observed. If two external 32-MB devices are used, a 64-MB block is observed.

Table 15-107. SDRAM Addressing Space

| Module Name | Base Address | Size |
|----------------------------------------|--------------|---------------------------------------------------------------------------------------------|
| EMIF1 EMIF2 -CS0-SDRAM ⁽¹⁾ | 0x8000 0000 | 0 to 1 GB - programmable in DMM (see Section 15.2, Dynamic Memory Manager) |
| EMIF1 EMIF2 -CS1-SDRAM ⁽²⁾ | 0xC000 0000 | 0 to 1 GB - programmable in DMM (see Section 15.2, Dynamic Memory Manager) |

⁽¹⁾ The addressing space is interleaved on two LPDDR memory controllers (EMIF1, EMIF2), each activating their CS0 line. These CSs can address 64, 128, 256, 512, 1024, or 2048MBs. Interleaving occurs at 128-byte granularity. Both memories must be of the same kind (SDRAM or NVM). EMIF1-CS0 base address is always 0x8000 0000 at reset, and occupies a 1-GB address space at reset (interleaving disabled at reset).

⁽²⁾ The addressing space is interleaved on two LPDDR memory controllers (EMIF1, EMIF2), each activating its CS1 line. These CSs are programmable to 64, 128, 256, 512, or 1024MBs. Interleaving occurs at 128-byte granularity. EMIF1-CS1 and EMIF2-CS1 are disabled at reset. Their base address is programmable to achieve a continuous address space with the respective CS0, regardless of the programmed address range. EMIF1-CS1 is disabled if the EMIF1-CS0 memory density is set to 2048MB (2GB) when interleaving is disabled, or if the EMIF1-CS0 + EMIF2-CS0 memory density is set to 1024MB (1GB) when interleaving is enabled.

When addressing SDRAM, if the [EMIF_SDRAM_CONFIG\[28:27\] REG_IBANK_POS](#) field is set to 0, the EMIF uses the following 3-bit fields, to determine the mapping from source address to SDRAM row, column, bank, and chip-select:

- [EMIF_SDRAM_CONFIG\[6:4\] REG_IBANK](#)
- [EMIF_SDRAM_CONFIG\[3\] REG_EBANK](#)
- [EMIF_SDRAM_CONFIG\[2:0\] REG_PAGESIZE](#)

If the [EMIF_SDRAM_CONFIG\[28:27\] REG_IBANK_POS](#) field is set to 1, 2, or 3, the EMIF uses the 4 fields to determine the mapping from source address to SDRAM row, column, bank, and chip-select:

- [EMIF_SDRAM_CONFIG\[6:4\] REG_IBANK](#)
- [EMIF_SDRAM_CONFIG\[3\] REG_EBANK](#)
- [EMIF_SDRAM_CONFIG\[2:0\] REG_PAGESIZE](#)
- [EMIF_SDRAM_CONFIG\[9:7\] REG_ROWSIZE](#)

In all cases the EMIF considers its SDRAM address space to be a single logical block regardless of the number of physical devices or whether the devices are mapped across 1 or 2 EMIF chip-selects.

For [EMIF_SDRAM_CONFIG\[28:27\] REG_IBANK_POS = 0](#), [Table 15-108](#) and [Table 15-109](#) show which source address bits, MAddr, map to the SDRAM row, column, bank, and chip-select bits for all combinations of [REG_IBANK](#), [REG_EBANK](#) and [REG_PAGESIZE](#).

For [EMIF_SDRAM_CONFIG\[28:27\] REG_IBANK_POS != 0](#), [Table 15-111](#) to [Table 15-112](#) shows which source address bits, MAddr, map to the SDRAM row, column, bank, and chip-select bits for all combinations of [REG_IBANK](#), [REG_EBANK](#), [REG_PAGESIZE](#), and [REG_ROWSIZE](#).

Table 15-108. L3 Address to SDRAM Address Mapping for 16-Bit SDRAM (EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 0)

| 4096 | 0 | 3 | 3 | row | | | | | | | | | | | | bank | col |

For `EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 0`, the effect of the address-mapping scheme is that as the source address increments across SDRAM page boundaries, the EMIF moves onto the same page in the next bank in the current device (`lpddr2i_cs1[0]n`, $i = 1$ or 2). This movement along the banks of the current device continues until the page has been accessed in all banks in the current device. The EMIF then proceeds to the same page in the next device (if `EMIF_SDRAM_CONFIG[3] REG_EBANK = 1`, `lpddr2i_cs1[1]n`, $i = 1$ or 2) and proceeds through the same page in all its banks before moving over to the next page in the first device (`lpddr2i_cs1[0]n`, $i = 1$ or 2). The EMIF exploits this traversal across internal banks and chip-selects while remaining on the same page to maximize the number of open SDRAM banks within the overall SDRAM space.

Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across two chip-selects) open at a time, and can interleave among all of them.

In [Table 15-110](#), [Table 15-111](#), and [Table 15-112](#), the L3 Address to SDRAM Address Mapping is given. In each case, we will have x bits for bank, followed by y bits for row, followed by z bit for CS, followed by s bit for bank and t bit for col in MAddr[31:N] (x, y, z, s and t are given depending on the [EMIF_SDRAM_CONFIG](#) bit field values).

**Table 15-110. L3 Address to SDRAM Address Mapping for EMIF_SDRAM_CONFIG[28:27]
REG_IBANK_POS = 1 and EMIF_SDRAM_CONFIG_2[27] REG_EBANK_POS = 0**

| MAddr[31:N] | | | | |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------|---------------------------------------------------------------------------|-----------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| Bank Address | Row Address | Chip-Select | Bank Address | Column Address |
| Number of bits defined by EMIF_SDRAM_CONFIG [6] REG_IBANK | Number of bits defined by EMIF_SDRAM_CONFIG [9:7] REG_ROWSIZE | Number of bits defined by EMIF_SDRAM_CONFIG [3] REG_EBANK | Number of bits defined by EMIF_SDRAM_CONFIG [5:3] REG_IBANK | Number of bits defined by EMIF_SDRAM_CONFIG [2:0] REG_PAGESIZE |
| = 0: 0 bit | = 0: 9 bits | = 0: 0 bit | = 0: 0 bit | = 0: 8 bits |
| = 1: 0 bit | = 1: 10 bits | = 1: 1 bit | = 1: 1 bit | = 1: 9 bits |
| | = 2: 11 bits | | = 2: 2 bits | = 2: 10 bits |
| | = 3: 12 bits | | = 3: 2 bits | = 3: 11 bits |
| | = 4: 13 bits | | | |
| | = 5: 14 bits | | | |
| | = 6: 15 bits | | | |
| | = 7: 16 bits | | | |

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

There are 2 times the REG_IBANK bit field because it gives the number of bank bits depending on their place in the MAddr.

For EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS=1, the EMIF interleaves banks the same as EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 0, but the interleaving of banks within a device (per chip-select) is limited to 4 banks. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across two chip-selects) open at a time, but can only interleave among 8 of them.

Table 15-111. L3 Address to SDRAM Address Mapping for EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 2 and EMIF_SDRAM_CONFIG_2[27] REG_EBANK_POS = 0

| MAddr[31:N] | | | | |
|-------------------------------------------------------------------|---------------------------------------------------------------------|-----------------------------------------------------------------|-----------------------------------------------------------------|----------------------------------------------------------------------|
| Bank Address | Row Address | Chip-Select | Bank Address | Column Address |
| Number of bits defined by EMIF_SDRAM_CONFIG [6:5] REG_IBANK | Number of bits defined by EMIF_SDRAM_CONFIG [9:7] REG_ROWSIZE | Number of bits defined by EMIF_SDRAM_CONFIG [3] REG_EBANK | Number of bits defined by EMIF_SDRAM_CONFIG [4] REG_IBANK | Number of bits defined by EMIF_SDRAM_CONFIG [2:0] REG_PAGESIZE |
| = 0: 0 bit | = 0: 9 bits | = 0: 0 bit | = 0: 0 bit | = 0: 8 bits |
| = 1: 0 bit | = 1: 10 bits | = 1: 1 bit | = 1: 1 bit | = 1: 9 bits |
| = 2: 1 bit | = 2: 11 bits | | | = 2: 10 bits |
| = 3: 2 bits | = 3: 12 bits | | | = 3: 11 bits |
| | = 4: 13 bits | | | |
| | = 5: 14 bits | | | |
| | = 6: 15 bits | | | |
| | = 7: 16 bits | | | |

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

For `EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 2`, the EMIF interleaves banks the same as `EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 0`, but the interleaving of banks within a device (per chip-select) is limited to 2 banks. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across two chip-selects) open at a time, but can only interleave among 4 of them.

Table 15-112. L3 Address to SDRAM Address Mapping for `EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 3` and `EMIF_SDRAM_CONFIG_2[27] REG_EBANK_POS = 0`

| MAddr[31:N] | | | |
|-------------------------------------------------------------------------------|---------------------------------------------------------------------------------|-----------------------------------------------------------------------------|----------------------------------------------------------------------------------|
| Bank Address | Row Address | Chip-Select | Column Address |
| Number of bits defined by <code>EMIF_SDRAM_CONFIG[6:4]</code> REG_IBANK | Number of bits defined by <code>EMIF_SDRAM_CONFIG[9:7]</code> REG_ROWSIZE | Number of bits defined by <code>EMIF_SDRAM_CONFIG[3]</code> REG_EBANK | Number of bits defined by <code>EMIF_SDRAM_CONFIG[2:0]</code> REG_PAGESIZE |
| = 0: 0 bit | = 0: 9 bits | = 0: 0 bit | = 0: 8 bits |
| = 1: 1 bit | = 1: 10 bits | = 1: 1 bit | = 1: 9 bits |
| = 2: 2 bits | = 2: 11 bits | | = 2: 10 bits |
| = 3: 3 bits | = 3: 12 bits | | = 3: 11 bits |
| | = 4: 13 bits | | |
| | = 5: 14 bits | | |
| | = 6: 15 bits | | |
| | = 7: 16 bits | | |

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

For [EMIF_SDRAM_CONFIG\[28:27\]](#) REG_IBANK_POS = 3, the EMIF cannot interleave banks within a device (per chip-select). However, it can still interleave banks between the two chip-selects. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across 2 chip-selects) open at a time, but can only interleave among 2 of them.

Since the EMIF interleave among less number of banks when [EMIF_SDRAM_CONFIG\[28:27\]](#) REG_IBANK_POS != 0, these cases are lower in performance than the [EMIF_SDRAM_CONFIG\[28:27\]](#) REG_IBANK_POS = 0 case. Thus these cases are only recommended to be used along with partial array self-refresh where performance can be traded off for power savings.

Table 15-113. L3 Address to SDRAM Address Mapping for EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 1 and EMIF_SDRAM_CONFIG_2[27] REG_EBANK_POS = 1

| MAddr[31:N] | | | | |

| = 0: 0 bit | = 0: 0 bit | = 0: 9 bits | = 0: 0 bit | = 0: 8 bits |
| = 1: 1 bit | = 1: 0 bit | = 1: 10 bits | = 1: 1 bit | = 1: 9 bits |
| | = 2: 1 bit | = 2: 11 bits | = 2: 1 bit | = 2: 10 bits |
| | = 3: 2 bits | = 3: 12 bits | = 3: 1 bit | = 3: 11 bits |
| | | = 4: 13 bits | | |
| | | = 5: 14 bits | | |
| | | = 6: 15 bits | | |
| | | = 7: 16 bits | | |

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

The interleaving of banks within a device (per chip-select) is limited to two banks. The EMIF cannot interleave banks between the two chip-selects. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across two chip-selects) open at a time, but can interleave among only 2 of them.

Table 15-115. L3 Address to SDRAM Address Mapping for EMIF_SDRAM_CONFIG[28:27] REG_IBANK_POS = 3 and EMIF_SDRAM_CONFIG_2[27] REG_EBANK_POS = 1

| MAddr[31:N] | | | |
|----------------------------------------------------------------|------------------------------------------------------------------|--------------------------------------------------------------------|----------------------------------------------------------------------|
| Chip-Select | Bank Address | Row Address | Column Address |
| Number of bits defined by EMIF_SDRAM_CONFIG[3] REG_EBANK | Number of bits defined by EMIF_SDRAM_CONFIG[6:4] REG_IBANK | Number of bits defined by EMIF_SDRAM_CONFIG[9:7] REG_ROWSIZE | Number of bits defined by EMIF_SDRAM_CONFIG[2:0] REG_PAGESIZE |
| = 0: 0 bit | = 0: 0 bit | = 0: 9 bits | = 0: 8 bits |
| = 1: 1 bit | = 1: 1 bit | = 1: 10 bits | = 1: 9 bits |
| | = 2: 2 bits | = 2: 11 bits | = 2: 10 bits |
| | = 3: 3 bits | = 3: 12 bits | = 3: 11 bits |
| | | = 4: 13 bits | |
| | | = 5: 14 bits | |
| | | = 6: 15 bits | |
| | | = 7: 16 bits | |

NOTE: N = 1 for 16-bit SDRAM, and N = 2 for 32-bit SDRAM.

The EMIF cannot interleave banks within a device (per chip-select) or between the two chip-selects. Thus, the EMIF can keep a maximum of 16 banks (8 internal banks across two chip-selects) open at a time, but cannot interleave among them.

Because the EMIF interleaves among fewer banks when REG_IBANK_POS != 0 or REG_EBANK_POS = 1, these cases are lower in performance than the REG_IBANK_POS = 0 case. Thus, these cases are recommended to be used only along with partial array self-refresh, where performance can be traded for power savings.

15.3.4.12 NVM Address Mapping

NVM are always decoded CS - bank - row - column, and cannot be interleaved.

15.3.4.13 LPDDR2 SDRAM Initialization

On coming out of reset if the [EMIF_SDRAM_CONFIG](#)[31:29] REG_SDRAM_TYPE field in the SDRAM Config register is equal to 4 or 5, the EMIF performs a LPDDR2 initialization sequence as follows:

1. Drives $\text{lpddr2i_cke}[1:0]$ (i = 1 or 2 and j = 0 or 1) high and starts to continuously issues NOP commands.
2. After 16 SDRAM refresh rate intervals, issues a PRECHARGE-ALL command. The SDRAM refresh rate is as defined in the [EMIF_SDRAM_REF_CTRL](#)[15:0] REG_REFRESH_RATE field description.
3. Issues a RESET command.
4. The software then performs the LPDDR2 initialization using the EMIF's [EMIF_LPDDR2_MODE_REG_CFG](#) and [EMIF_LPDDR2_MODE_REG_DATA](#) registers. The software must enable refreshes by setting the [EMIF_LPDDR2_MODE_REG_CFG](#)[30] REG_REFRESH_EN bit field to 1 during the last MRW command.

The EMIF also performs the initialization sequence whenever the [EMIF_SDRAM_CONFIG](#) is written and the LPDDR2 initialization was not performed previously because SDRAM_REF_CTRL[31] REG_INITREF_DIS was set to 0. Once the EMIF performs initialization, rewriting the SDRAM Config register will not cause re-initialization.

NOTE: The values of the different bit fields in the [EMIF_SDRAM_CONFIG](#) and [EMIF_SDRAM_CONFIG_2](#) registers are fixed by the System Control Module (SCM) at reset. These values must be modified by the header feature in the ROM code configuration or by the initial boot image running from an external XIP booting memory or internal RAM (see [Section 27.4.8, Image Format](#)). They must not be modified during run time as they reflect the used hardware LPDDR2 SDRAM and/or NVM memory configurations.

The EMIF does not perform any transactions until the LPDDR2 initialization sequence is complete.

When the EMIF comes out of reset, the delay time in step 2 resulting from the 16 refresh rate intervals + 8 cycles is approximately $16 * \text{EMIF_SDRAM_REF_CTRL}[15:0] \text{ REG_REFRESH_RATE} / \text{input frequency}$.

15.3.5 External Memory Interface (EMIF) Programming Guide

15.3.5.1 EMIF Low-Level Programming Models

This section covers the low-level hardware programming sequences for configuration and usage of the EMIF module.

Please, have in mind that the following programming sequences are double as there are two EMIF modules (EMIF1 and EMIF2) with the same register mapping but with different register addresses.

15.3.5.1.1 Global Initialization

Table 15-116. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Power, Reset and Clock Management (PRCM) | The module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management . |
| Interrupt sub-module of the MPU | The Interrupt requests from the EMIF have to be enabled (unmasked), see Chapter 17, Interrupt Controllers . |
| DMM (Dynamic Memory Management) | The EMIF is a slave to the DMM module. The DMM should be enabled and configured for communication with LPDDR2 memories. See Section 15.2, DMM |

15.3.5.1.1.1 EMIF Module Global Initialization

This procedure initializes the EMIF after a power-on reset. It works only with LPDDR2 (Low Power Double Data Rate 2) SDRAM or NVM types. The unused bits in all registers should be written with zeros. The values of the Shadow Registers are loaded in their corresponding registers a frequency update sequence is performed.

NOTE: The values of the different bit fields in the [EMIF_SDRAM_CONFIG](#) and [EMIF_SDRAM_CONFIG_2](#) registers are fixed by the Control Module at reset. These values must be modified by the header feature in the ROM code configuration or by the initial boot image running from an external XIP booting memory or internal RAM (see [Section 27.4.8, Image Format](#)). They must not be modified during run time because they reflect the used hardware LPDDR2 SDRAM and/or NVM memory configurations.

Table 15-117. EMIF Global Initialization

| Step | Register/ Bit Field / Programming Model | Value |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|-------|
| IF : RAM = SDRAM | | |
| (Optional) Remove NVM mode on CS1 in order to select the two CSs of DDRAM for each EMIF instance. | EMIF_SDRAM_CONFIG_2 [30] REG_CS1NVMEN | 0 |
| Assign the external bank address bits from lower or higher OCP address as shown in Table 15-110 , Table 15-111 , Table 15-112 , Table 15-113 , Table 15-114 , and Table 15-115 . | EMIF_SDRAM_CONFIG_2 [27] REG_EBANK_POS | 0x- |
| ELSE : (RAM = NVM) | | |
| Enable CS1 for LPDDR2-NVM. | EMIF_SDRAM_CONFIG_2 [30] REG_CS1NVMEN | 1 |
| Define the number of the row buffers inside connected LPDDR2-NVM device. | EMIF_SDRAM_CONFIG_2 [5:4] REG_RDBNUM | 0x- |
| Define the row data buffer size of connected LPDDR2-NVM device. | EMIF_SDRAM_CONFIG_2 [2:0] REG_RDBSIZE | 0x- |
| Assign the external bank address bits from lower or higher OCP address as shown in Table 15-110 , Table 15-111 , Table 15-112 , Table 15-113 , Table 15-114 , and Table 15-115 . | EMIF_SDRAM_CONFIG_2 [27] REG_EBANK_POS | 0x- |
| ENDIF | | |
| Select the SDRAM type (S2 or S4) | EMIF_SDRAM_CONFIG [31:29] REG_SDRAM_TYPE | 0x- |
| Assign internal bank address bits from L3 address as shown in Table 15-108 , Table 15-109 , Table 15-110 , Table 15-111 , Table 15-112 , Table 15-113 , Table 15-114 , and Table 15-115 . | EMIF_SDRAM_CONFIG [28:27] REG_IBANK_POS | 0x- |
| Enable/disable DLL. | EMIF_SDRAM_CONFIG [20] REG_DDR_DISABLE_DLL | 0x- |
| Choose between 32-bit or 16-bit wide SDRAM data bus. | EMIF_SDRAM_CONFIG [15:14] REG_NARROW_MODE | 0x- |
| Define CAS latency when accessing connected SDRAM devices. | EMIF_SDRAM_CONFIG [13:10] REG_CL | 0x- |

Table 15-117. EMIF Global Initialization (continued)

| Step | Register/ Bit Field / Programming Model | Value |
|-----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------|---------------------|
| Define the number of row address bits of connected SDRAM device. | EMIF_SDRAM_CONFIG[9:7] REG_ROWSIZE | 0x- |
| Define the number of banks inside connected SDRAM device. | EMIF_SDRAM_CONFIG[6:4] REG_IBANK | 0x- |
| Define whether SDRAM accesses use 1 or 2 chip-select lines. | EMIF_SDRAM_CONFIG[3] REG_EBANK | 0x- |
| Define the internal page size of connected SDRAM device. | EMIF_SDRAM_CONFIG[2:0] REG_PAGESIZE | 0x- |
| Configure the DDR PHY physical layer to the SDRAM (Read Latency for the read data from SDRAM in number of DDR clock cycles) | EMIF_DDR_PHY_CTRL_1 ⁽¹⁾ | 0x----- |
| Write the Shadow register of the EMIF_DDR_PHY_CTRL_1 with the same value. | EMIF_DDR_PHY_CTRL_1_SHDW ⁽¹⁾ | EMIF_DDR_PHY_CTRL_1 |
| Initialize MR LPDDR2 registers. | External LPDDR2 initialization, see Table 15-120 | |
| Configure the DDR PHY physical layer to the SDRAM parameters. | EMIF_DDR_PHY_CTRL_2 | 0x----- |
| Define timings and clock parameters | EMIF Timing Initialization, see Table 15-118 | |
| Configure the SDRAM Output Impedance Calibration parameters | EMIF Output Impedance Calibration Mode, see Table 15-121 | |
| Configure the Temperature Alert parameters | EMIF Temperature Monitoring Mode, see Table 15-130 | |
| (Optional) Configure the Performance Counter Config Register | EMIF_PERF_CNT_CFG | 0x-00--00- |
| (Optional) Configure the Performance Counter Master Region Select Register | EMIF_PERF_CNT_SEL | 0x--0---0- |
| (Optional) Configure the System and Low-Latency L3 Threshold Maxima and the priority counter of an old command. | EMIF_L3_CONFIG | 0x0-0-00-- |
| Clear all eventual previous indications of treated interrupts. | EMIF_IRQSTATUS_SYS, EMIF_IRQSTATUS_LL | 0x- |
| (Optional) Enable System L3 interrupt for Command or Address Error. | EMIF_IRQENABLE_SET_SYS[0] REG_EN_ERR_SYS | 0x1 |
| (Optional) Enable Low-Latency L3 interrupt for Command or Address Error. | EMIF_IRQENABLE_SET_LL[0] REG_EN_ERR_LL | 0x1 |

⁽¹⁾ Values loaded in these registers depend on OPP.

Table 15-118. Sub-process call summary for Main Sequence - EMIF Global Initialization

| Sub-process Name | Crossreference |
|----------------------------------------|------------------------------|
| EMIF Timing Initialization | Table 15-119 |

|----------------------------------------------------|-----------------------------------------|---------|
| Change REG_LP_MODE bitfield from 0x4 to any value. | EMIF_PWR_MGMT_CTRL[10:8] REG_LP_MODE | 0x- |
| Write the shadow register of EMIF_PWR_MGMT_CTRL. | EMIF_PWR_MGMT_CTRL_SHDW | 0x----- |

15.3.5.1.2.6 EMIF LPDDR2-SDRAM Deep Power-Down Mode

Table 15-128. EMIF LPDDR2-SDRAM Deep Power-Down Mode Entering

| Step | Register/ Bit Field / Programming Model | Value |
|-----------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|---------|
| Define the number of DDR clock cycles after which the EMIF puts the external SDRAM in Power saving mode, when EMIF is idle. | EMIF_PWR_MGMT_CTRL[3:0] REG_CS_TIM | 0x- |
| Enable (enter) the Deep Power-Down mode | EMIF_PWR_MGMT_CTRL[11] REG_DPD_EN | 0x1 |
| Write the shadow register of EMIF_PWR_MGMT_CTRL. | EMIF_PWR_MGMT_CTRL_SHDW | 0x----- |

Table 15-129. EMIF LPDDR2-SDRAM Deep Power-Down Mode Exiting

| Step | Register/ Bit Field / Programming Model | Value |
|--------------------------------------------------|-----------------------------------------|---------|
| Clear REG_DPD_EN bit. | EMIF_PWR_MGMT_CTRL[11] REG_DPD_EN | 0 |
| Write the shadow register of EMIF_PWR_MGMT_CTRL. | EMIF_PWR_MGMT_CTRL_SHDW | 0x----- |

NOTE: After Deep Power-Down exit, software must perform initialization as specified in [Table 15-120](#).

15.3.5.1.2.7 EMIF Temperature Monitoring Mode

Table 15-130. EMIF Temperature Monitoring Mode

| Step | Register/ Bit Field / Programming Model | Value |
|------------------------------------------------------------------------------------------------------------|----------------------------------------------------|---------|
| Determine which chip-select 1 or 0 is used for Temperature Alert Polling | EMIF_TEMP_ALERT_CONFIG[31:30] REG_TA_CS1/0EN | 0x- |
| Define the interval (number of refresh periods) between temperature alert polls. | EMIF_TEMP_ALERT_CONFIG[21:0] REG_TA_REFINTERVAL | 0x----- |
| Define the width of the physical memory device | EMIF_TEMP_ALERT_CONFIG[27:26] REG_TA_DEVWDT | 0x- |
| Define which external byte lanes contain a device for temperature monitoring (which devices to be polled). | EMIF_TEMP_ALERT_CONFIG[25:24] REG_TA_DEVCNT | 0x- |

Table 15-130. EMIF Temperature Monitoring Mode (continued)

| Step | Register/ Bit Field / Programming Model | Value |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|-------|
| (Optional) Enable the issuing of a temperature alert poll on Self-Refresh exit (poll for temperature change every time EMIF exits Self-Refresh, Active Power-Down, and Precharge Power-Down modes). | EMIF_TEMP_ALERT_CONFIG [28] REG_TA_SFEXITEN | 0x1 |
| Enable System L3 interrupt for SDRAM temperature alert. | EMIF_IRQENABLE_SET_SYS [1] REG_EN_TA_SYS | 0x1 |
| Enable Low-Latency L3 interrupt for SDRAM temperature alert. | EMIF_IRQENABLE_SET_LL [1] REG_EN_TA_LL | 0x1 |

15.3.5.1.3 EMIF Events Servicing

15.3.5.1.3.1 Interrupt Servicing

This section covers the event servicing (interrupt treatment) of the EMIF module.

Please, have in mind that the following Interrupt mechanism is double as there are two EMIF modules with different register addresses and 2 Interrupt lines - EMIF1_IRQ and EMIF2_IRQ.

Table 15-131. EMIF Event Servicing

| Step | Register/ Bit Field / Programming Model | Value |
|-------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|--------|
| Read the status registers: | EMIF_IRQSTATUS_SYS , EMIF_IRQSTATUS_LL | |
| IF : | EMIF_IRQSTATUS_SYS [0] | =1 |
| Read the Error Log register and determine the Addressing mode, Command type and the Connection ID of the first errored transaction. | EMIF_L3_ERR_LOG | |
| Clear corresponding status flag | EMIF_IRQSTATUS_SYS [0] REG_ERR_SYS | 0x1 |
| ELSE IF : | EMIF_IRQSTATUS_SYS [1] | =1 |
| Update the REFRESH_RATE to the required value as per the temperature change. | EMIF_SDRAM_REF_CTRL [15:0] REG_REFRESH_RATE | 0x---- |
| Clear corresponding status flag | EMIF_IRQSTATUS_SYS [1] REG_TA_SYS | 0x1 |
| ELSE IF: | EMIF_IRQSTATUS_LL [0] | =1 |

NOTE: The values of the different bit fields in the [EMIF_SDRAM_CONFIG](#) and [EMIF_SDRAM_CONFIG2](#) registers are fixed by the Control Module (CM) at reset. These values must be modified by the header feature in the ROM code configuration or by the initial boot image running from an external XIP booting memory or internal RAM (see [Section 27.4.8, Image Format](#)). They must not be modified during run time as they reflect the used hardware LPDDR2 SDRAM and/or NVM memory configurations.

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------------------|
| 31:29 | REG_SDRAM_TYPE | SDRAM Type selection. Set to 4 for LPDDR2-S4, Set to 5 for LPDDR2-S2 All other value are reserved. | RW | 0x- ⁽¹⁾ |
| 28:27 | REG_IBANK_POS | Internal bank position. Set to 0 to assign internal bank address bits from L3 address as shown in Table 15-108 and Table 15-109 . Set to 1, 2, or 3 to assign internal bank address bits from L3 address as shown in Table 15-110 , Table 15-111 , and Table 15-112 . | RW | 0x- ⁽¹⁾ |
| 26:24 | RESERVED | Reserved | RW | 0x0 |
| 23 | REG_DDR2_DDQS | DDR2 differential DQS enable. Set to 0 for single-ended DQS. Set to 1 for differential DQS. This bit is only for DDR2 mode; because the device supports LPDDR2, this bit is don't care. | RW | 0x- ⁽¹⁾ |
| 22:21 | RESERVED | Reserved | RW | 0x- ⁽¹⁾ |
| 20 | REG_DDR_DISABLE_DLL | Disable DLL select. Set to 1 to disable DLL inside SDRAM. | RW | 0x- ⁽¹⁾ |
| 19:16 | RESERVED | Reserved | RW | 0x0 |
| 15:14 | REG_NARROW_MODE | SDRAM data bus width. Set to 0 for 32-bit and set to 1 for 16-bit. All other values are reserved. | RW | 0x- ⁽¹⁾ |
| 13:10 | REG_CL | CAS Latency (referred to as read latency (RL) in some SDRAM specs). The value of this field defines the CAS latency to be used when accessing connected SDRAM devices. Value of 3, 4, 5, 6, 7, and 8 (CAS latency of 3, 4, 5, 6, 7, and 8) are supported for LPDDR2-SDRAM. All other values are reserved. Also program the EMIF_DDR_PHY_CTRL_1 [3:0] REG_READ_LATENCY | RW | 0x- ⁽¹⁾ |

⁽¹⁾ Value loaded by the control module at reset (see [Section 18.6.4, SYSCTRL_GENERAL_WKUP Register Summary](#)).

| Bits | Field Name | Description | Type | Reset |
|------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------------------|
| 9:7 | REG_ROWSIZE | Row Size. Defines the number of row address bits of connected SDRAM devices. Set to 0 for 9 row bits, Set to 1 for 10 row bits, Set to 2 for 11 row bits, Set to 3 for 12 row bits, Set to 4 for 13 row bits, Set to 5 for 14 row bits, Set to 6 for 15 row bits, Set to 7 for 16 row bits. This field is only used when EMIF_SDRAM_CONFIG [28:27] REG_IBANK_POS field is set to 1, 2, or 3 or REG_EBANK_POS field in EMIF_SDRAM_CONFIG_2 register is set to 1. | RW | 0x- ⁽²⁾ |
| 6:4 | REG_IBANK | Internal Bank setup. Defines number of banks inside connected SDRAM devices. Set to 0 for 1 bank, Set to 1 for 2 banks, Set to 2 for 4 banks, Set to 3 for 8 banks. All other values are reserved. | RW | 0x- ⁽²⁾ |
| 3 | REG_EBANK | External chip-select setup. Defines whether SDRAM accesses will use 1 or 2 chip-select lines. Set to 0 to use pad_cs_o_n[0] only. Set to 1 to use pad_cs_o_n[1:0]. This bit will automatically be set to 0 if EMIF_SDRAM_CONFIG_2 [30] REG_CS1NVMEN field is set to 1. | RW | 0x- ⁽²⁾ |
| 2:0 | REG_PAGESIZE | Page Size. Defines the internal page size of connected SDRAM devices. Set to 0 for 256-word page (8 column bits), Set to 1 for 512-word page (9 column bits), Set to 2 for 1024-word page (10 column bits), Set to 3 for 2048-word page (11 column bits). All other values are reserved. | RW | 0x- ⁽²⁾ |

⁽²⁾ Value loaded by the control module at reset (see [Section 18.6.4, SYSCTRL_GENERAL_WKUP Register Summary](#)).

Table 15-142. EMIF_SDRAM_REF_CTRL

| | | | |
|-------------------------|--------------------------------|-----------------|----------------|
| Address Offset | 0x0000 0010 | Instance | EMIF1 EMIF2 |
| Physical Address | 0x4C00 0010 0x4D00 0010 | | |
| Description | SDRAM Refresh Control Register | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-----------------|----------|----|----|----|----|----|----|----|----|----|----|----|------------------|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| REG_INITREF_DIS | RESERVED | | | | | | | | | | | | REG_REFRESH_RATE | | | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31 | REG_INITREF_DIS | Initialization and Refresh disable. When set to 1, EMIF will disable SDRAM initialization and refreshes, but will carry out SDRAM write/read transactions. | RW | 0 |
| 30:16 | RESERVED | Reserved | R | 0 |
| 15:0 | REG_REFRESH_RATE | Refresh Rate. Value in this field is used to define the rate at which connected SDRAM devices will be refreshed. SDRAM refresh rate = DDR_PHY_CLK / REG_REFRESH_RATE. If REG_REFRESH_RATE < (8 × REG_T_RFC) + REG_T_RP + REG_T_RCD + 20, then it will be loaded with (8 × REG_T_RFC) + REG_T_RP + REG_T_RCD + 20. This is done to avoid lock-up situations when illegal values are programmed. For a description of DDR_PHY_CLK, see Section 15.3.3, EMIF Integration . | RW | 0x0000 |

| RESERVED | | | | | | | | REG_T_CKESR | REG_ZQ_ZQCS | | | | | | | | REG_T_TDQSCKMAX | REG_T_RFC | | | | | | | | REG_T_RAS_MAX | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|-----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:24 | RESERVED | Reserved | R | 0x0 |
| 23:21 | REG_T_CKESR | Minimum number of DDR clock cycles for which LPDDR2 must remain in Self Refresh, minus one. | RW | 0x2 |
| 20:15 | REG_ZQ_ZQCS | Number of DDR clock cycles for a ZQCS command, minus one. | RW | 0x08 |
| 14:13 | REG_T_TDQSCKMAX | Number of DDR clock cycles that satisfy the tDQSCkmax timing parameter minus one. The recommended setting for 400MHz DDR clock and tDQSCkMAX = 5.5 ns is 2.5 ns x 3 clks = 7.5 ns. 3 clks - 1 = 0x2. | RW | 01 |
| 12:4 | REG_T_RFC | Minimum number of DDR clock cycles from Refresh or Load Mode to Refresh or Activate, minus one. | RW | 0x115 |
| 3:0 | REG_T_RAS_MAX | Maximum number of reg_refresh_rate intervals from Activate to Precharge command. This field must be equal to ((tRASmax / tREFI)-1) rounded down to the next lower integer. Value for REG_T_RAS_MAX can be calculated as follows: If tRASmax = 120 us and tREFI = 15.7 us, then REG_T_RAS_MAX = ((120/15.7)-1) = 6.64. Round down to the next lower integer. Therefore, the programmed value must be 6. | RW | 0x1 |

| 31:16 | RESERVED | | R | 0x0000 |
| 15:12 | REG_PD_TIM | Power Mangement timer for Power-Down. The EMIF will put the external SDRAM in Power-Down mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 4. Set to 0 to immediately enter Power-Down mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks. | RW | 0x0 |
| 11 | REG_DPD_EN | Deep Power Down enable. Set to 0 for normal operation. Set to 1 to enter deep power-down mode. This mode will override the reg_lp_mode field setting. | RW | 0 |
| 10:8 | REG_LP_MODE | Automatic Power Management enable Set to 1: Reserved Set to 2: Self-refresh mode Set to 4: Power-down mode All other values will disable automatic power management. | RW | 0x0 |
| 7:4 | REG_SR_TIM | Power Mangement timer for Self Refresh. The EMIF will put the external SDRAM in Self Refresh mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 2. Set to 0 to immediately enter Self Refresh mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks. | RW | 0x0 |
| 3:0 | REG_CS_TIM | Power Mangement timer for Clock Stop. The EMIF will put the external SDRAM in Clock Stop mode after the EMIF is idle for these number of DDR clock cycles and if reg_lp_mode field is set to 1. Set to 0 to immediately enter Clock Stop mode. Set to 1 for 16 clocks, set to 2 for 32 clocks, set to 3 for 64 clocks, set to 4 for 128 clocks, set to 5 for 256 clocks, set to 6 for 512 clocks, set to 7 for 1024 clocks, set to 8 for 2048 clocks, set to 9 for 4096 clocks, set to 10 for 8192 clocks, set to 11 for 16384 clocks, set to 12 for 32768 clocks, set to 13 for 65536 clocks, set to 14 for 131072 clocks, and set to 15 for 262144 clocks. | RW | 0x0 |

| | | | |
|-------------------------|------------------------------------------------------------|-----------------|----------------|
| Address Offset | 0x0000 0054 | Instance | EMIF1 EMIF2 |
| Physical Address | 0x4C00 0054 0x4D00 0054 | | |
| Description | Config Register | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|--------------------|----|----|----|----------|----|----|----|-------------------|----|----|----|----------|----|----|----|------------------|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | REG_SYS_THRESH_MAX | | | | RESERVED | | | | REG_LL_THRESH_MAX | | | | RESERVED | | | | REG_PR_OLD_COUNT | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:28 | RESERVED | Reserved for future use. | R | 0x0 |
| 27:24 | REG_SYS_THRESH_MAX | System L3 Threshold Maximum. The number of commands the system interface can consume in the command FIFO. The value is used to determine when to stop future request, writing a zero will reserve no space for the associated interface. In the event the value is set to zero and a request is seen for that interface, the command FIFO will assume a value of 1. Since the low-latency interface has effectively a higher priority, the only way for the system interface to use all command FIFO entries is to set the REG_LL_THRESH_MAX to zero. | RW | 0x7 |
| 23:20 | RESERVED | Reserved for future use. | R | 0x0 |
| 19:16 | REG_LL_THRESH_MAX | Low-latency L3 Threshold Maximum. The number of commands the low latency interface can consume in the command FIFO. The value is used to determine when to stop future request, writing a zero will reserve no space for the associated interface. In the event the value is set to zero and a request is seen for that interface, the command FIFO will assume a value of 1. | RW | 0x7 |
| 15:8 | RESERVED | Reserved for future use. | R | 0x0 |
| 7:0 | REG_PR_OLD_COUNT | Priority Raise Old Counter. Number of memory transfers after which the EMIF momentarily raises the priority of old commands in the L3 Command FIFO. | RW | 0xFF |

Table 15-186. EMIF_READ_IDLE_CTRL

| | | | |
|-------------------------|------------------------------------------------------------|-----------------|----------------|
| Address Offset | 0x0000 0098 | Instance | EMIF1 EMIF2 |
| Physical Address | 0x4C00 0098 0x4D00 0098 | | |
| Description | Read Idle Control Register | | |
| Type | RW | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|-------------------|----|----|----|----------|----|----|----|------------------------|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | REG_READ_IDLE_LEN | | | | RESERVED | | | | REG_READ_IDLE_INTERVAL | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:20 | RESERVED | Reserved for future use. | R | 0x0 |
| 19:16 | REG_READ_IDLE_LEN | The Read Idle Length field determines the minimum size (reg_read_idle_len-1 EMIF_FCLK clock cycles) of Read Idle window for the read idle detection as well as the force read idle time. | RW | 0x5 |
| 15:9 | RESERVED | Reserved for future use. | R | 0x0 |
| 8:0 | REG_READ_IDLE_INTERVAL | The Read Idle Interval field determines the maximum interval ((REG_READ_IDLE_INTERVAL - 1) * 64 EMIF_FCLK clock cycles) between read idle detections or force. A value of zero disables the read idle function. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:30 | DLL_MASTER_SENSITIVITY | This field defines the level of sensitivity of the DLL master: the lower the value, the more sensitive the DLL is to PVT variation. The recommended setting is 0x2. | RW | 0x0 |
| 29:26 | REG_PHY_FREEZE_DELAY_CODE_POSTAMBLE | Postamble time respected by the DATA PHY freezing the DLL slave code after reads. Use the TI-validated value of 0x1. | RW | 0x0 |
| 25:22 | REG_PHY_FREEZE_DELAY_CODE_PREAMBLE | Preamble time respected by the DATA PHY before freezing the DLL slave code during reads. Use the TI-validated value of 0x2. | RW | 0x0 |
| 21:12 | REG_DLL_MASTER_SW_CODE_CTRL | DLL delay code when in software override mode, typically at OPP_BOOT. Keep at maximum delay (0x1FF) for this case. Override mode is controlled through DLL_OVERRIDE register fields in PRCM. | RW | 0x1FF |
| 11:4 | REG_DLL_SLAVE_DLY_CTRL | DLL slave delay ratio control For the typical SDRAM frequency of 400-MHz and DLL reference clock frequency of 100-MHz, this number must be set to 0x40 (1/4-th of 0xFF). 0x40: DLL ratio of 4 0x80: DLL ratio of 2 0xFF: DLL ratio of 1 | RW | 0xFF |
| 3:0 | REG_READ_LATENCY | This field defines the read latency for the read data from SDRAM in number of DDR clock cycles. The REG_READ_LATENCY must be set to EMIF_SDRAM_CONFIG[13:10] REG_CL + EMIF_SDRAM_TIM_3 [14:13] REG_T_TDQSKMAX. The write latency (WL) is tied to the RL. See the LPDDR SDRAM standard. | RW | 0x0 |

15.4 General-Purpose Memory Controller

15.4.1 GPMC Overview

The general-purpose memory controller (GPMC) is an unified memory controller dedicated to interfacing external memory devices:

- Asynchronous SRAM-like memories and application-specific integrated circuit (ASIC) devices
- Asynchronous, synchronous, and page mode (only available in non-muxed mode) burst NOR flash devices
- NAND Flash
- Pseudo-SRAM devices

15.4.2 GPMC Environment

This section describes the GPMC application fields from an environment point of view (external connections). It describes GPMC connectivity options, and gives three possible interfaces.

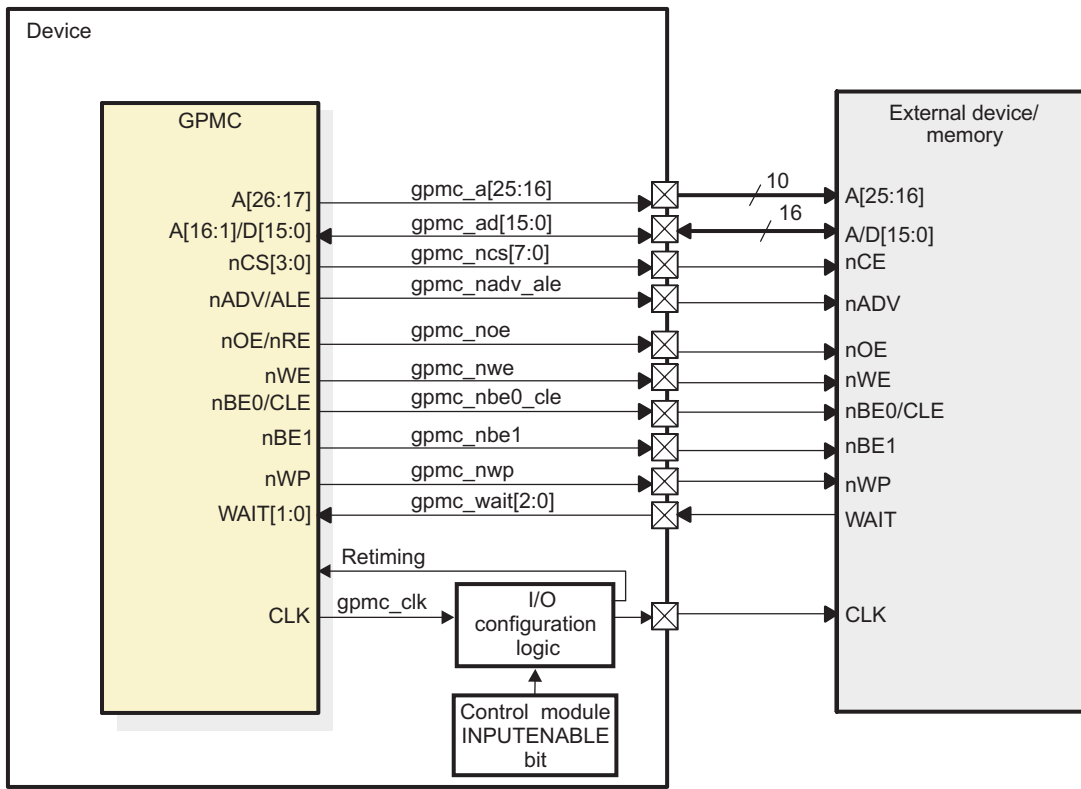

15.4.2.1 GPMC Modes

This section shows three GPMC external connections options:

- [Figure 15-50](#) shows a connection between the GPMC and a 16-bit synchronous address/data-multiplexed (or AAD-multiplexed, but this protocol use less address pins) external memory device ([Figure 15-50](#)).
- [Figure 15-50](#) shows a connection between the GPMC and a 16-bit synchronous nonmultiplexed external memory device ([Figure 15-51](#)).
- [Figure 15-52](#) shows a connection between the GPMC and a 16-bit NAND device ([Figure 15-52](#)).

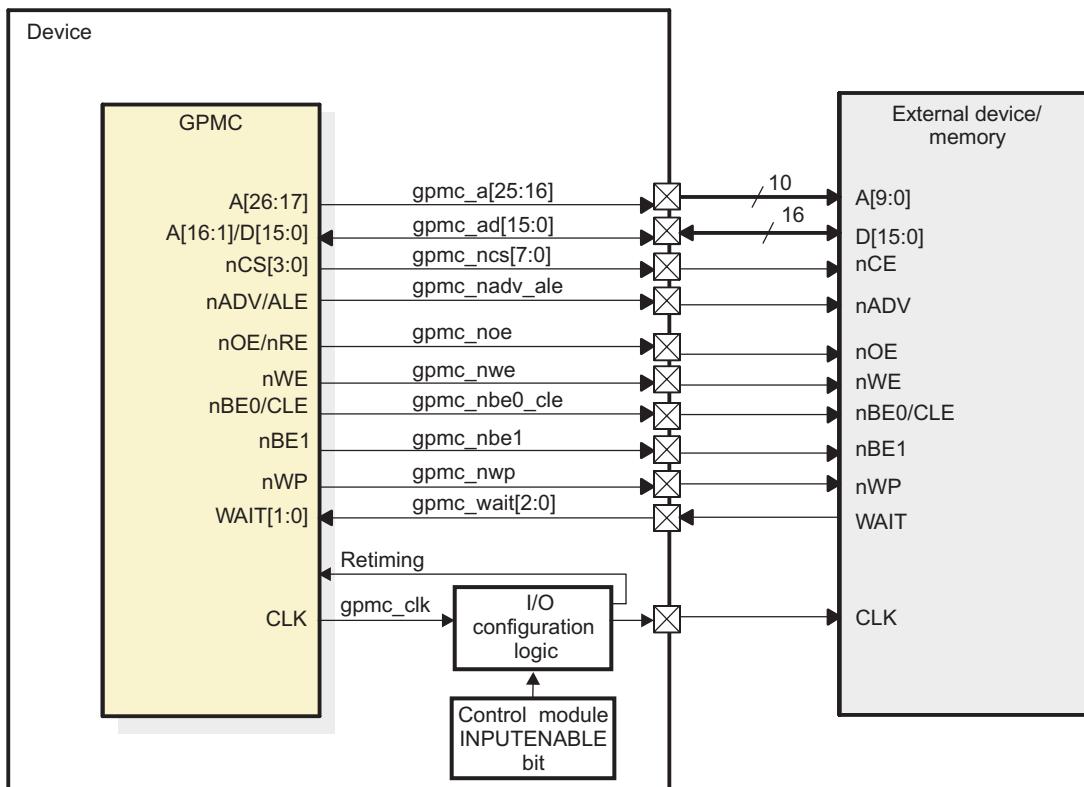

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for multiplexed and nonmultiplexed protocol). Hence, an 8-bit device must be connected to the D[7:0] / gpmc_ad[7:0] data bus (rather than D[15:8] / gpmc_ad[15:8]) of the GPMC controller. This limits the use of 8-bit wide device interfacing to byte-alias access.

Figure 15-50. GPMC to 16-Bit Address/Data-Multiplexed Memory

Figure 15-51. GPMC to 16-Bit Nonmultiplexed Memory

gpmc-045

Figure 15-52. GPMC to 8-Bit NAND Device

gpmc-003

15.4.2.2 GPMC Signals

Table 15-216 lists the GPMC subsystem I/O pins.

Table 15-216. GPMC I/O Description

| Pin Name | I/O | Description |
|----------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| gpmc_a[25:16] | O | Address |
| gpmc_ad[15:0] | I/O | Data |
| gpmc_ncs[7:0] | O | Chip-selects (active low) |
| gpmc_clk | O ⁽¹⁾ | Clock generated for the external memory or device |
| gpmc_nadv_ale | O | Address valid (active low). Also used as address latch enable (active high) for NAND protocol memories. |
| gpmc_noe_nre | O | Output enable (active low). Also used as read enable (active low) for NAND protocol memories. |
| gpmc_nwe | O | Write enable (active low) |
| gpmc_nbe0_cle | O | Lower-byte enable (active low). Also used as command latch enable for NAND protocol memories. |
| gpmc_nbe1 | O | Upper-byte enable (active low). |
| gpmc_nwp | O | Write protect (active low) |
| gpmc_wait[2:0] | I | External wait signal for NOR and NAND protocol memories. The wait signals can be mapped on any of the chip-select. |
| gpmc_io_dir | O | gpmc_ad[15:0] signal direction control: Low during transmit (for write access: data OUT from GPMC to memory), High during receive (for read access: data IN from memory to GPMC) |

⁽¹⁾ This output signal is also used as retiming input (the INPUTENABLE bit in the corresponding pad configuration register must be set to 1).

Table 15-217 shows the use of address and data GPMC controller pins based on the type of external device.

Table 15-217. GPMC Pin Multiplexing Options

| GPMC Pin | Multiplexed Address Data 16-Bit Device | Nonmultiplexed Address Data 16-Bit Device With LIMITED- ADDRESS Bit Enabled | 16-Bit NAND Device | 8-Bit NAND Device |
|-------------|----------------------------------------------|--------------------------------------------------------------------------------------|-----------------------|----------------------|

| gpmc_a[17] | A18 | A2 | Not used | Not used |
| gpmc_a[16] | A17 | A1 | Not used | Not used |
| gpmc_ad[15] | A16/D15 | D15 | D15 | Not used |
| gpmc_ad[14] | A15/D14 | D14 | D14 | Not used |
| gpmc_ad[13] | A14/D13 | D13 | D13 | Not used |
| gpmc_ad[12] | A13/D12 | D12 | D12 | Not used |
| gpmc_ad[11] | A12/D11 | D11 | D11 | Not used |
| gpmc_ad[10] | A11/D10 | D10 | D10 | Not used |
| gpmc_ad[9] | A10/D9 | D9 | D9 | Not used |
| gpmc_ad[8] | A9/D8 | D8 | D8 | Not used |
| gpmc_ad[7] | A8/D7 | D7 | D7 | D7 |
| gpmc_ad[6] | A7/D6 | D6 | D6 | D6 |
| gpmc_ad[5] | A6/D5 | D5 | D5 | D5 |
| gpmc_ad[4] | A5/D4 | D4 | D4 | D4 |
| gpmc_ad[3] | A4/D3 | D3 | D3 | D3 |
| gpmc_ad[2] | A3/D2 | D2 | D2 | D2 |
| gpmc_ad[1] | A2/D1 | D1 | D1 | D1 |
| gpmc_ad[0] | A1/D0 | D0 | D0 | D0 |

When using non-multiplexed memories, it is recommended to enable [GPMC_CONFIG\[1\] LIMITEDADDRESS](#). This bit forces A[26:11] to 1 on the GPMC I/O side. Thus, only 2Kbytes of memory address space is accessible regardless of the memory size.

With all device types, the GPMC does not drive unnecessary address lines. They stay at their reset value of 0x00.

Address mapping supports address/data-multiplexed 16-bit wide devices:

- The NOR flash memory controller still supports non-multiplexed address and data memory devices.
- Multiplexing mode can be selected through the [GPMC_CONFIG1_i\[9:8\] MUXADDDATA](#) bit field (i = 0 to 7).
- Asynchronous page mode is not supported for multiplexed address and data devices.

NOTE: The numbering for A (address) is starting from 1 instead of 0 such as D (data) because the A0 signal is handled within the GPMC but is not driven to any pad. The signal is only relevant to 8-bit accesses and this configuration is not recommended. If such a memory or device is connected, only every second word in the memory is accessible, that is, each 16-bit aligned 8-bit word is mapped but not the non-16-bit aligned ones. Any access to a non-aligned one will actually result in accessing the associated aligned one, at address A1 instead of address A.

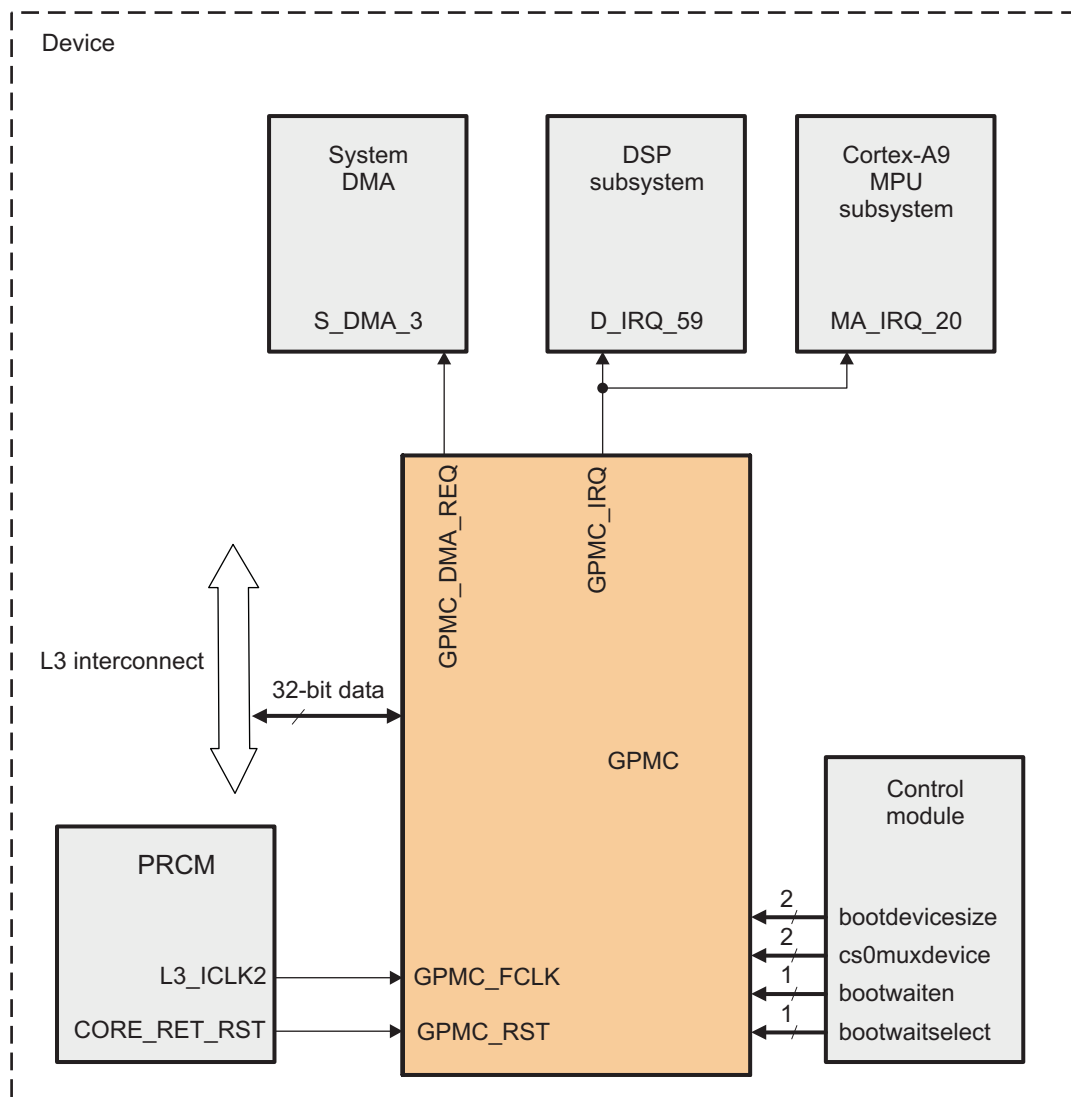

15.4.3 GPMC Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

- No STANDBY hardware handshake
- No wake-up request
- One system direct memory access (sDMA) request
- One interrupt request to the Cortex-A9 MPU Interrupt Controller (MA_IRQ) and to DSP subsystem (D_IRQ)
- One clock for functional and interface domains

Figure 15-53 shows GPMC integration.

Figure 15-53. GPMC Integration

gpmc-004

Table 15-218, Table 15-219 and Table 15-220 summarize the integration of the module in the device.

Table 15-218. GPMC Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-up Capability | Interconnect |
| GPMC | PD_CORE | No | L3 |

NOTE:

- For information about operation performance point (OPP) configuration description, see [Section 3.1.1.1.2, Module Level Clock Management](#) in [Chapter 3, Power, Reset, and Clock Management](#).

Table 15-219. GPMC Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| GPMC | GPMC_FCLK | L3_ICLK2 | PRCM | Functional clock |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| GPMC | GPMC_RST | CORE_RET_RST | PRCM | GPMC reset |

- For DMA source description, see [Section 15.4.4.6, GPMC DMA Requests](#).

15.4.4 GPMC Functional Description

The GPMC basic programming model offers maximum flexibility to support various access protocols for each of the eight configurable chip-selects. Use optimal chip-select settings, based on the characteristics of the external device:

- Different protocols can be selected to support generic asynchronous or synchronous random-access devices (NOR flash, SRAM) or to support specific NAND devices.
- The address and the data bus can be multiplexed on the same external bus.
- Read and write access can be independently defined as asynchronous or synchronous.
- System requests (byte, 16-bit word, burst) are performed through single or multiple accesses. External access profiles (single, multiple with optimized burst length, native- or emulated-wrap) are based on external device characteristics (supported protocol, bus width, data buffer size, native-wrap support).
- System burst read or write requests are synchronous-burst (multiple-read or multiple-write). When neither burst nor page mode is supported by external memory or ASIC devices, system burst read or write requests are translated to successive single synchronous or asynchronous accesses (single reads or single writes). 8-bit wide devices are supported only in single synchronous or single asynchronous read or write mode.
- To simulate a programmable internal-wait state, an external wait pin can be monitored to dynamically control external access at the beginning (initial access time) of and during a burst access.

Each control signal is controlled independently for each chip-select. The internal functional clock of the GPMC (GPMC_FCLK) is used as a time reference to specify the following:

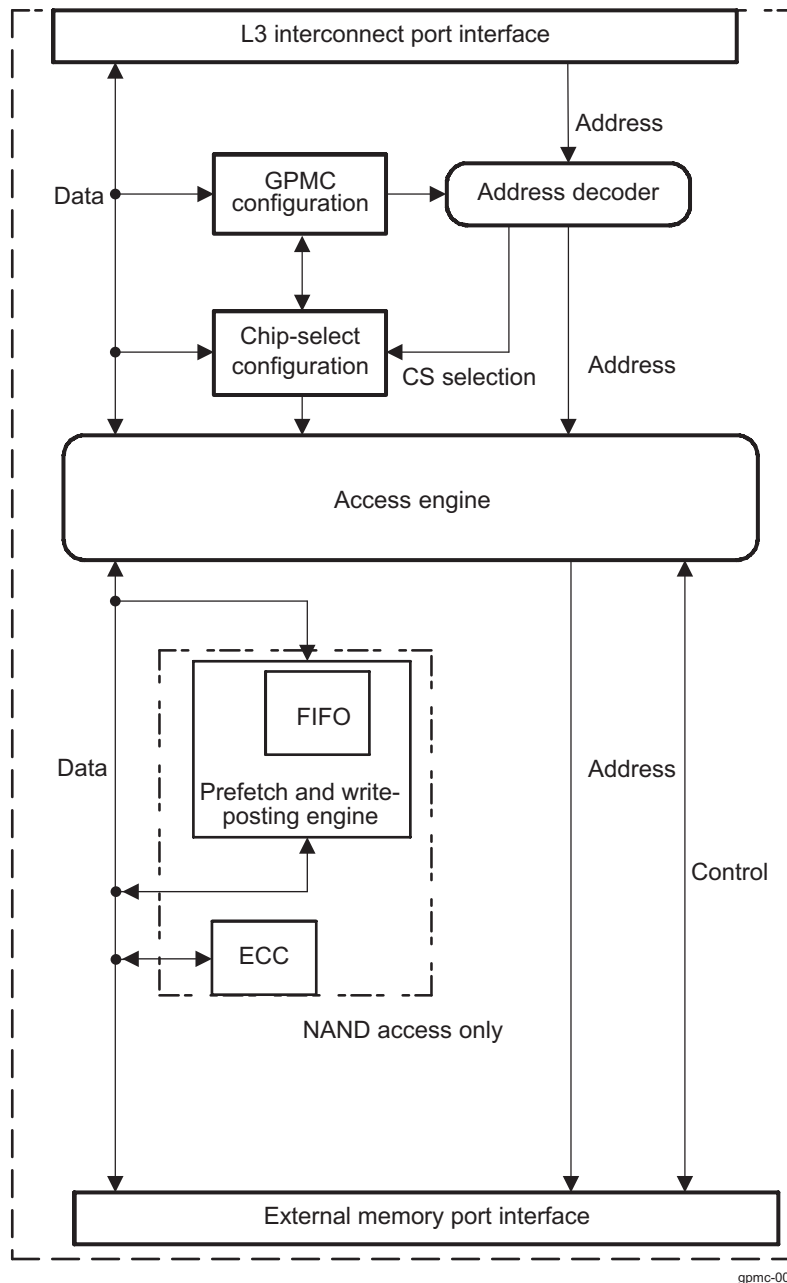

- Read- and write-access duration
- Most GPMC external interface control-signal assertion and deassertion times
- Data-capture time during read access
- External wait-pin monitoring time
- Duration of idle time between accesses, when required

15.4.4.1 GPMC Block Diagram

Figure 15-54 shows the GPMC functional block diagram. The GPMC consists of six blocks:

- L3 interconnect port interface
- Address decoder, GPMC configuration, and chip-select configuration register file
- Access engine
- Prefetch and write-posting engine
- Error correction code engine (ECC)
- External device/memory port interface

Figure 15-54. GPMC Block Diagram

The GPMC can access various external devices through the L3 Interconnect. The flexible programming model allows a wide range of attached device types and access schemes.

Based on the programmed configuration bit fields stored in the GPMC registers, the GPMC is able to generate all control signals timing depending on the attached device and access type.

Given the chip-select decoding and its associated configuration registers, the GPMC selects the appropriate device type control signals timing.

15.4.4.2 GPMC Clock Configuration

Table 15-221 describes the GPMC clocks.

Table 15-221. GPMC Clocks

| Signal | I/O ⁽¹⁾ | Description |
|-----------|--------------------|-----------------------------------------------------------------|
| GPMC_FCLK | I | Functional and interface clock |
| gpmc_clk | O | External clock provided to synchronous external memory devices. |

⁽¹⁾ I = Input; O = Output

The gpmc_clk is generated by the GPMC from the internal GPMC_FCLK clock. The source of the GPMC_FCLK is described in [Table 15-219](#). The gpmc_clk is configured via the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER field (for i = 0 to 7) as shown in [Table 15-222](#).

Table 15-222. gpmc_clk Configuration

| Source Clock | GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER | gpmc_clk Generated Clock Provided to External Memory Device |
|--------------|--------------------------------------------------------|----------------------------------------------------------------|
| GPMC_FCLK | 00 | GPMC_FCLK |
| | 01 | GPMC_FCLK/2 |
| | 10 | GPMC_FCLK/3 |
| | 11 | GPMC_FCLK/4 |

15.4.4.3 GPMC Software Reset

The GPMC can be reset by software through the [GPMC_SYSCONFIG\[1\]](#) SOFTRESET bit. Setting the bit to 1 enables an active software reset that is functionally equivalent to a hardware reset. Hardware and software resets initialize all GPMC registers and the finite state-machine (FSM) immediately and unconditionally. The [GPMC_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. The software must ensure that the software reset completes before doing GPMC operations.

15.4.4.4 GPMC Power Management

GPMC power is supplied by the CORE power domain, and GPMC power management complies with system power-management guidelines.

[Table 15-223](#) describes power-management features available for the GPMC module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For descriptions of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.6, Clock Management Functional Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 15-223. GPMC Local Power Management Features

| Feature | Registers | Description |
|------------------------|---------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| Clock Auto Gating | GPMC_SYSCONFIG[0] AUTOIDLE bit | This bit allows a local power optimization inside the module, by gating the GPMC_FCLK clock upon the internal activity. |
| Slave Idle Modes | GPMC_SYSCONFIG[4:3] SIDLEMODE bit field | Force-idle, No-idle and Smart-idle wakeup modes are available |
| Clock Activity | N/A | Feature not available |
| Master Standby Modes | N/A | Feature not available |
| Global Wake-up Enable | N/A | Feature not available |
| Wake-up Sources Enable | N/A | Feature not available |

15.4.4.5 GPMC Interrupt Requests

The GPMC generates one interrupt event as shown in [Figure 15-53](#) :

- The interrupt request goes from GPMC (GPMC_IRQ) to the Cortex-A9 MPU subsystem : MA_IRQ_20 and to the DSP subsystem : D_IRQ_59.

[Table 15-224](#) lists the event flags, and their mask, that can cause module interrupts.

Table 15-224. GPMC Interrupt Events

| Event Flag | Event Mask | Sensitivity | Map to | Description |
|---------------------------------------------------------------|---------------------------------------------------------------|-------------|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GPMC_IRQSTATUS [10] WAIT2EDGE DETECTIONSTATUS | GPMC_IRQENABLE [10] WAIT2EDGE DETECTIONENABLE | Edge | D_IRQ_59 and MA_IRQ_20 | Wait2 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait2 signal. The rising or falling edge detection of Wait2 is selected through GPMC_CONFIG [10] WAIT2PINPOLARITY |
| GPMC_IRQSTATUS [9] WAIT1EDGE DETECTIONSTATUS | GPMC_IRQENABLE [9] WAIT1EDGE DETECTIONENABLE | Edge | D_IRQ_59 and MA_IRQ_20 | Wait1 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait1 signal. The rising or falling edge detection of Wait1 is selected through GPMC_CONFIG [9] WAIT1PINPOLARITY |
| GPMC_IRQSTATUS [8] WAIT0EDGE DETECTIONSTATUS | GPMC_IRQENABLE [8] WAIT0EDGE DETECTIONENABLE | Edge | D_IRQ_59 and MA_IRQ_20 | Wait0 edge detection interrupt: Triggered if a rising or falling edge is detected on the gpmc_wait0 signal. The rising or falling edge detection of Wait0 is selected through GPMC_CONFIG [8] WAIT0PINPOLARITY |
| GPMC_IRQSTATUS [1] TERMINAL COUNTSTATUS | GPMC_IRQENABLE [1] TERMINAL COUNTENABLE | Level | D_IRQ_59 and MA_IRQ_20 | Terminal count event: Triggered on prefetch process completion, that is when the number of currently remaining data to be requested reaches zero |
| GPMC_IRQSTATUS [0] FIFOEVENTSTATUS | GPMC_IRQENABLE [0] FIFOEVENTENABLE | Level | D_IRQ_59 and MA_IRQ_20 | FIFO event interrupt: Indicates FIFO levels availability for in Write-Posting mode and prefetch mode. GPMC_PREFETCH_CONFIG1 [2] DMAMODE shall be set to 0. |

15.4.4.6 GPMC DMA Requests

The GPMC generates one DMA event as shown in [Figure 15-53](#) :

- From GPMC (GPMC_DMA_REQ) to the system DMA (sDMA) : S_DMA_3.

15.4.4.7 L3 Interconnect Interface

The GPMC L3 interconnect interface is a pipelined interface including an 16 x 32-bit word write buffer.

Any system host can issue external access requests through the GPMC.

The device system can issue the following requests through this interface:

- One 8-bit / 16-bit / 32-bit interconnect access (read/write)
- Two incrementing 32-bit interconnect accesses (read/write)
- Two wrapped 32-bit interconnect accesses (read/write)
- Four incrementing 32-bit interconnect accesses (read/write)
- Four wrapped 32-bit interconnect accesses (read/write)
- Eight incrementing 32-bit interconnect accesses (read/write)
- Eight wrapped 32-bit interconnect accesses (read/write)

Only linear burst transactions are supported; interleaved burst transactions are not supported. Only power-of-two-length precise bursts 2 x 32, 4 x 32, 8 x 32 or 16 x 32 with the burst base address aligned on the total burst size are supported (this limitation applies to incrementing bursts only).

This interface also provides one interrupt and one DMA request line, for specific event control.

It is recommended to program the ATTACHEDDEVICEPAGELENGTH field ([GPMC_CONFIG1_i\[24:23\]](#)) according to the effective attached device page length and to enable WRAPBURST bit ([GPMC_CONFIG1_i\[31\]](#)) if the attached device supports wrapping burst.

However, it is possible to emulate wrapping burst on a non-wrapping memory by providing relevant addresses within the page or splitting transactions. Bursts larger than the memory page length are chopped into multiple bursts transactions. Due to the alignment requirements, a page boundary is never crossed.

15.4.4.8 GPMC Address and Data Bus

The current application supports GPMC connection to NAND devices and to address/data-multiplexed memories or devices. Connection to address/data-nonmultiplexed memories or devices is supported with a limited address range of 2 Kbytes.

Depending on the GPMC configuration of each chip-select, address and data bus lines that are not required for a particular access protocol are not updated (changed from current value) and are not sampled when input (input data bus).

- When the [GPMC_CONFIG\[1\]](#) LIMITEDADDRESS bit is set to 1, A26-A11 are not modified during an external memory access. This limits the memory address space to 2K-byte regardless of the memory size.
- For address/data-multiplexed and AAD-multiplexed NOR devices, the address is multiplexed on the data bus.
- 8-bit wide NOR devices do not use GPMC I/O: gpmc_ad[15:8] for data (they are used for address if needed).
- 16-bit wide NAND devices do not use GPMC I/O: gpmc_a[25:16].
- 8-bit wide NAND devices do not use GPMC I/O: gpmc_a[25:16] and GPMC I/O: gpmc_ad[15:8].

CAUTION

Before accessing a chip-select configured with a nonmultiplexed protocol, set the LIMITEDADDRESS bit control.

15.4.4.8.1 GPMC I/O Configuration Setting

NOTE: In this section and next sections, the *i* in [GPMC_CONFIGx_i](#) stands for the GPMC chip-select *i* where *i* = 0 to 7.

To select a NAND device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b10
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit = 0b00

To select an address/data-multiplexed device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b00
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit = 0b10

To select an address/address/data-multiplexed device, program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b00
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit = 0b01

To select an address/data-nonmultiplexed device (limited to a 2K-byte address range), program the following register fields:

- [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE field = 0b00
- [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit = 0b00
- [GPMC_CONFIG\[1\]](#) LIMITEDADDRESS bit = 1

NOTE: The `GPMC_CONFIG1[1]` LIMITEDADDRESS bit only applies to address/data-nonmultiplexed devices; it has no effect on other device types (NAND, address/data-multiplexed).

15.4.4.8.2 GPMC CS0 Default Configuration at IC Reset

To ensure a correct external boot with a GPMC access from IC reset time on CS0, several external pins are sampled:

- The `sys_boot[4:0]` pins (device boundary) define the sequence of interfaces and devices to use for booting.
- The `sys_boot[5]` pin defines which group of booting sequences is preferred: memory booting (`sys_boot[5] = 0`) or peripheral booting (`sys_boot[5] = 1`).
- Additional pins are used to configure reset values in the `GPMC_CONFIG1_i` register (where $i = 0$) as detailed below and in [Table 15-225](#):
 - The `bootdevicesize` input pin (at the GPMC boundary) defines the size of the attached device on chip-select 0 and is used to configure the `GPMC_CONFIG1_i[13:12]` DEVICESIZE bits (where $i = 0$). The `BOOT_DEVICE_TYPE` signal is propagated from the system control module (SCM). Its value is fixed for the device at 0x1 at IC reset, which means that only 16-bit memories are supported for booting.
 - The `cs0muxdevice` input pin (at the GPMC boundary) selects whether the attached device to chip-select 0 is an address/data-multiplexed device or not. The input pin is used to configure the `GPMC_CONFIG1_i[9:8]` MUXADDDATA bit (where $i = 0$). The `CS0_MUX_DEVICE` signal is propagated from the SCM. Its value is fixed for the device at 0x2 at IC reset, which means that only address/data-multiplexed memories are supported for booting (that is, in a standalone way from memories connected to CS0).
 - The `bootwaiten` input pin (at the GPMC boundary) enables the monitoring on chip-select 0 of the WAIT pin at IC reset release time for read accesses. The input pin is used to configure the `GPMC_CONFIG1_i[22]` WAITREADMONITORING bit (where $i = 0$). The `BOOT_WAIT_ENABLE` signal is propagated from the system control module (SCM). When `sys_boot[5:0] = 0b11 1111`, the `BOOT_WAIT_ENABLE` signal is activated, causing the wait pin to be monitored for read accesses.
 - The `bootwaitselect` input pin selects the WAIT signal at IC reset release time between WAIT0 input pin, WAIT1 input pin or WAIT2 input pin. At IC reset release time, these three pins have different polarity.

Table 15-225. Boot Control Interface Input Signals Description

| Signal Name | Width | Description |
|-----------------------------|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>bootdevicesize</code> | 2 | Size of the device attached on CS0 0b00: 8-bit 0b01: 16-bit 0b10: Reserved 0b11: Reserved |
| <code>cs0muxdevice</code> | 2 | Multiplexing mode of the device on CS0 0b00: Nonmultiplexed device on CS0 0b01: AAD-multiplexed device on CS0 (address-address-data) 0b10: Address/Data-multiplexed device on CS0 0b11: Reserved |
| <code>bootwaiten</code> | 1 | Wait monitoring on CS0 at IC reset release time for read accesses 0: Wait pin is not monitored 1: Wait pin is monitored |
| <code>bootwaitselect</code> | 1 | Selection of the wait pin 0: WAIT0 input pin 1: WAIT1 input pin 2: WAIT2 input pin |

CAUTION

Using the internal boot code, the entire CS0 configuration can be modified before the first CS0 access. This modification of internal boot code is necessary for two external devices:

- NAND device attached to CS0
- Nonmultiplexed 2 Kbytes address range device attached to CS0

At reset time, the IC may boot from the internal ROM.

Reset values of the timing control parameters are defined to cope with direct boot on address and data multiplexed NOR Flash device, on non-multiplexed NOR Flash device or on any asynchronous device with large timing margins assuming a low GPMC_FCLK frequency (for example, 19.2Mhz) at boot time.

For a multiplexed access, the address 16 low-order bits are presented onto gpmc_ad[15:0] while the high-order bits are presented both onto gpmc_a[26:16]. If the external chip interface to the memories uses a 16-bit data bus, the high-order address bits are sampled on the address bus.

The reset values of timing parameters used at boot time are:

- CSONTIME = 1
- CSRDOFFTIME = 16
- ADVONTIME = 4
- ADVRDOFFTIME = 5
- OEONTIME = 6
- OEOFFTIME = 16
- RDACCESSTIME = 15
- RDCYCLETIME = 17

For an AAD-multiplexed access, all address bits are passed onto the data bus using two nADV rising edge. The first rising edge latches the address MSB down to bit 17 while the second rising edge latches address bits 16 down to 1. This configuration is only used for 16-bit memories.

The reset values of these timing parameters used at boot time are:

- ADVAADMUXONTIME = 1
- ADVAADMUXRDOFFTIME = 2
- OEAADMUXONTIME = 1
- OEAADMUXRDOFFTIME = 3

15.4.4.9 Address Decoder and Chip-Select Configuration

Addresses are decoded accordingly with the address request of the chip-select and the content of the chip-select base address register file, which includes a set of global GPMC configuration registers and eight sets of chip-select configuration registers.

The GPMC configuration register file is memory-mapped and can be read or written with byte, 16-bit word, or 32-bit word accesses. The register file should be configured as a noncacheable, nonbufferable region to prevent any desynchronization between host execution (write request) and the completion of register configuration (write completed with register updated). [Section 15.4.7, GPMC Register Manual](#) provides the GPMC register locations. For the map of GPMC memory locations, see [Chapter 2, Memory Mapping](#).

After the chip-select is configured, the access engine accesses the external device, drives the external interface control signals, and applies the interface protocol based on user-defined timing parameters and settings.

15.4.4.9.1 Chip-Select Base Address and Region Size

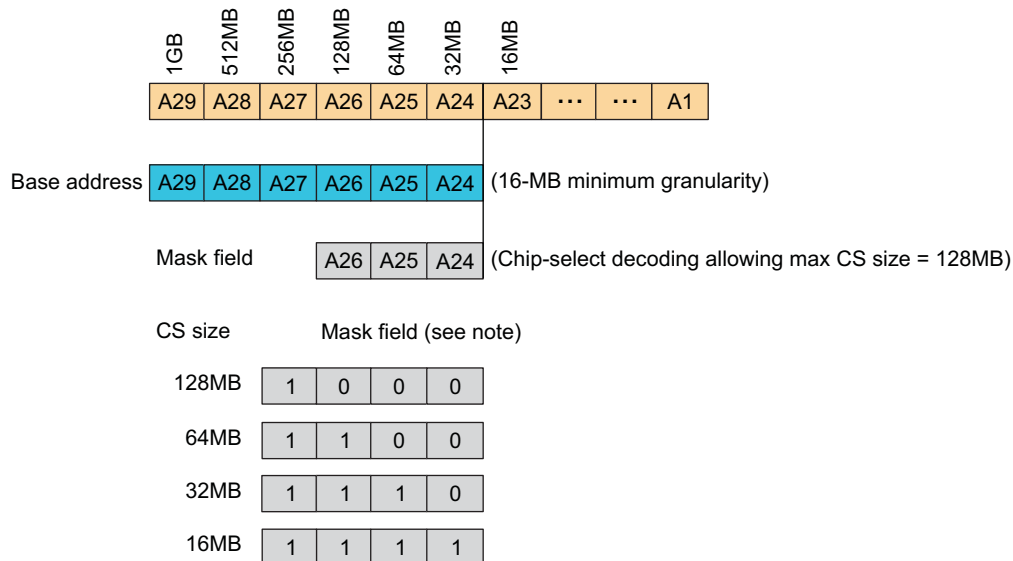

Any external memory or ASIC device attached to the GPMC external interface can be accessed by any device system host within the GPMC 1 Gbyte contiguous address space. For details, see [Chapter 2, Memory Mapping](#).

The GPMC 1G byte address space can be divided into a maximum of eight chip-select regions with programmable base address and programmable CS size. The CS size is programmable from 16M bytes to 128M bytes (must be a power-of-2) and is defined by the mask field. Attached memory smaller than the programmed CS region size is accessed through the entire CS region (aliasing).

Each chip-select has a 6-bit base address encoding and a 4-bit decoding mask, which must be programmed according to the following rules:

- The programmed chip-select region base address must be aligned on the chip-select region size address boundary and is limited to a power-of-2 address value. During access decoding, the register base address value is used for address comparison with the address-bit line mapping as described in [Figure 15-55](#) (with A0 as the device system byte-address line). Base address is programmed through the `GPMC_CONFIG7_i[5:0]` BASEADDRESS bit field
- The register mask is used to exclude some address lines from the decoding. A register mask bit field set to 0 suppresses the associated address line from the address comparison (incoming address bit line is don't care). The register mask value must be limited to the subsequent value, based on the desired chip-select region size. Any other value has an undefined result. When multiple chip-select regions with overlapping addresses are enabled concurrently, access to these chip-select regions is cancelled and a GPMC access error is posted. The mask field is programmed through the `GPMC_CONFIG7_i[11:8]` MASKADDRESS bit field.

Figure 15-55. Chip-Select Address Mapping and Decoding Mask

gpmc-006

Chip-select configuration (base and mask address or any protocol and timing settings) must be performed while the associated chip-select is disabled through the `GPMC_CONFIG7_i[6]` CSVALID bit (where i stands for the GPMC chip-select value, i = 0 to 7). In addition, a chip-select configuration can only be disabled if there is no ongoing access to that chip-select. This requires activity monitoring of the prefetch or write-posting engine if the engine is active on the chip-select. Also, the write buffer state must be monitored to wait for any posted write completion to the chip-select.

Any access attempted to a nonvalid GPMC address region (CSVALID disabled or address decoding outside a valid chip-select region) is not propagated to the external interface and a GPMC access error is posted. In case of chip-selects overlapping, an error is generated and no access will occur on either chip-select.

Chip-select 0 is the only chip-select region enabled after either a power-up or a GPMC reset.

CAUTION

Although the GPMC interface can drive up to 4 chip-selects, the frequency specified for this interface is for a specific load. If this load is exceeded, the maximum frequency cannot be reached. One solution is to implement a board with buffers, to allow the slowest device to maintain the total load on the lines.

15.4.4.9.2 Access Protocol**15.4.4.9.2.1 Supported Devices**

The access protocol of each chip-select can be independently specified through the [GPMC_CONFIG1_i\[11:10\]](#) DEVICETYPE parameter (where i = 0 to 7) for:

- Random-access synchronous or asynchronous memory like NOR flash, SRAM
- NAND flash asynchronous devices

NOTE: For more information about the NAND flash GPMC basic programming model and NAND support, see [Section 15.4.4.13](#), *NAND Device Basic Programming Model*, and [Section 15.4.4.13.1](#), *NAND Memory Device in Byte or Word 16 Stream Mode*.

15.4.4.9.2.2 Access Size Adaptation and Device Width

Each chip-select can be independently configured through the [GPMC_CONFIG1_i\[13:12\]](#) DEVICESIZE field (i = 0 to 7) to interface with a 16-bit wide device or an 8-bit wide device. System requests with data width greater than the external device data bus width are split into successive accesses according to both the external device data-bus width and little-endian data organization.

NOTE: The device does not provide the A0 byte address line required for random-byte addressable 8-bit wide device interfacing (for both multiplexed and nonmultiplexed protocol). It limits the use of 8-bit wide device interfacing to byte-alias accesses. This limitation is not applicable to NAND device interfacing (8-bit wide or 16-bit wide devices).

15.4.4.9.2.3 Address/Data-Multiplexing Interface

For random synchronous or asynchronous memory interfacing (DEVICETYPE = 0b00), an address- and data-multiplexing protocol can be selected through the [GPMC_CONFIG1_i\[9:8\]](#) MUXADDDATA bit field (i = 0 to 7). The nADV signal must be used as the external device address latch control signal. For the associated chip-select configuration, nADV assertion and deassertion time and nOE assertion time must be set to the appropriate value to meet the address latch setup/hold time requirements of the external device. See [Section 15.4.3](#), *GPMC Integration*.

NOTE: This address/data-multiplexing interface is not applicable to NAND device interfacing. NAND devices require a specific address, command, and data multiplexing protocol. See [Section 15.4.4.13](#), *NAND Device Basic Programming Model*.

15.4.4.9.3 External Signals**15.4.4.9.3.1 WAIT Pin Monitoring Control**

GPMC access time can be dynamically controlled using an external gpmc_wait pin when the external device access time is not deterministic and cannot be defined and controlled only using the GPMC internal RDACCESSTIME, WRACCESSTIME and PAGEBURSTACCESSTIME wait state generator.

The GPMC features three input wait pins: gpmc_wait2, gpmc_wait1 and gpmc_wait0. These pins allow control of external devices with different wait-pin polarity. They also allow the overlap of wait-pin assertion from different devices without affecting access to devices for which the wait pin is not asserted.

- The [GPMC_CONFIG1_i\[17:16\]](#) WAITPINSELECT field (i = 0 to 7) selects which input gpmc_wait pin is used for the device attached to the corresponding chip-select.
- The polarity of the wait pin is defined through the WAITxPINPOLARITY bit of the [GPMC_CONFIG](#) register. A wait pin configured to be active low means that low level on the WAIT signal indicates that the data is not ready and that the data bus is invalid. When WAIT is inactive, data is valid.

The GPMC access engine can be configured per CS to monitor the wait pin of the external memory device or not, based on the access type: read or write.

- The [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bit defines whether the wait pin should be monitored during read accesses or not.
- The [GPMC_CONFIG1_i\[21\]](#) WAITWRITEMONITORING bit defines whether the wait pin should be monitored during write accesses or not.

The GPMC access engine can be configured to monitor the wait pin of the external memory device asynchronously or synchronously with the GPMC_CLK clock, depending on the access type: synchronous or asynchronous (the [GPMC_CONFIG1_i\[29\]](#) READTYPE and [GPMC_CONFIG1_i\[27\]](#) WRITETYPE bits).

15.4.4.9.3.1.1 Wait Monitoring During an Asynchronous Read Access

When wait-pin monitoring is enabled for read accesses (WAITREADMONITORING), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the wait-deasserted state.

During asynchronous read accesses with wait-pin monitoring enabled, the wait pin must be at a valid level (asserted or deasserted) for at least two GPMC clock cycles before RDACCESSTIME completes, to ensure correct dynamic access-time control through wait-pin monitoring. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

In this context, RDACCESSTIME is used as a WAIT invalid timing window and is set to such a value that the wait pin is at a valid state two GPMC clock cycles before RDACCESSTIME completes.

Similarly, during a multiple-access cycle (for example, asynchronous read page mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-deasserted state. Wait-monitoring pipelining is also applicable to multiple accesses (access within a page).

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as asserted extends the current access time in the page. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a page, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive completes the current access time and starts the next access phase in the page. The data bus is considered valid, and data are captured during this clock cycle. In case of a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their related control timing value and according to the CYCLETIME counter status.

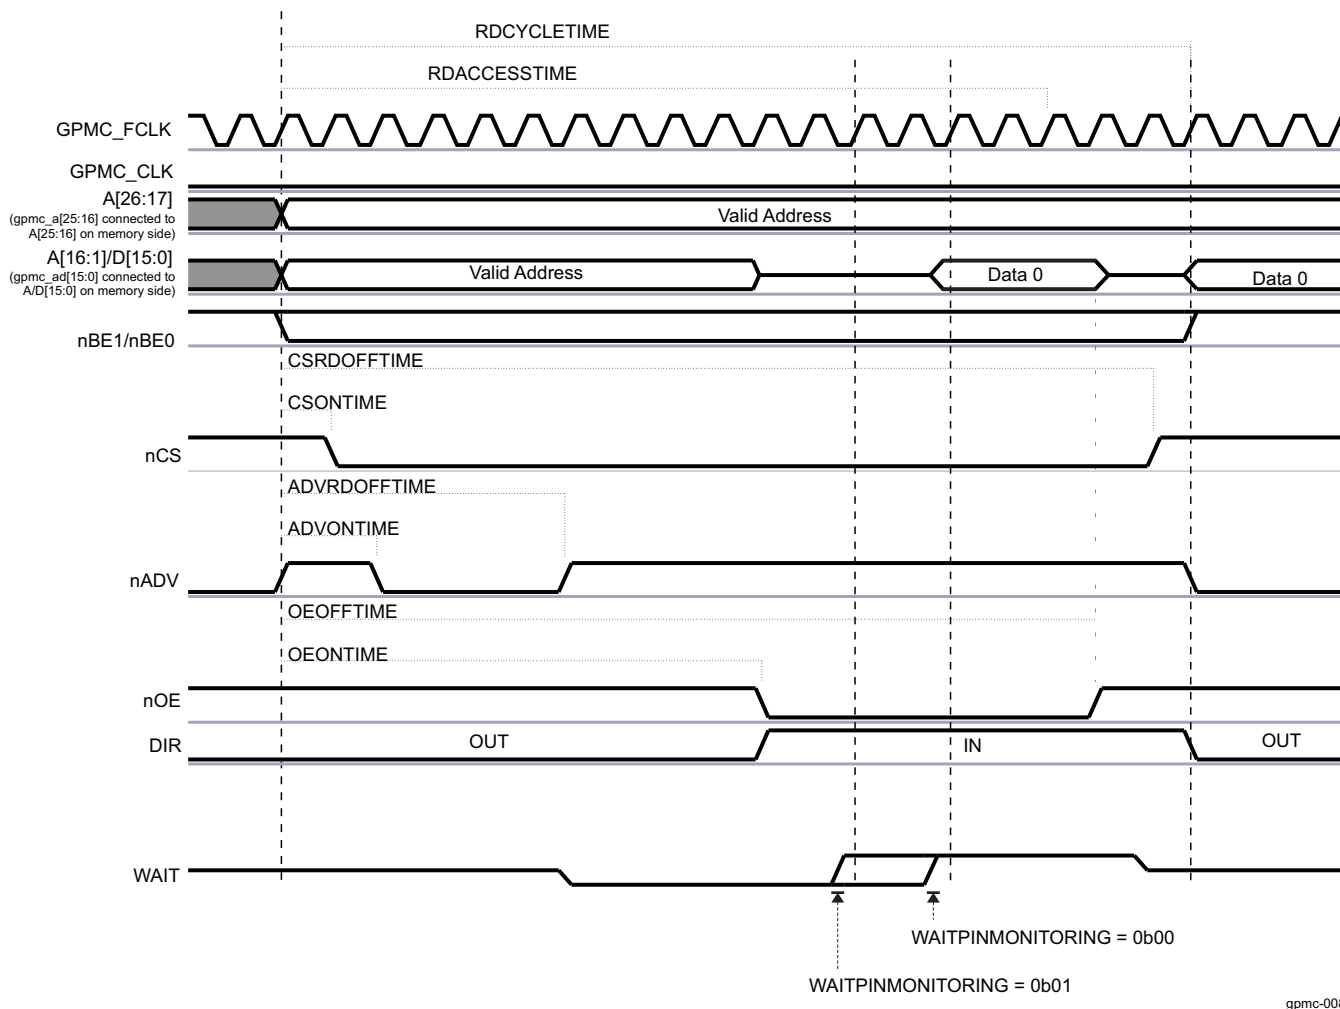

When a delay larger than two GPMC clocks must be observed between wait-pin deactivation time and data valid time (including the required GPMC and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data-capture time and the effective unlock of the CYCLETIME counter. This extra delay can be programmed in the [GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME field (i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin active or inactive detection, nor does it modify the two GPMC clocks pipelined detection delay.
- This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and no GPMC_CLK clock is provided to the external device. Still, GPMCFCLKDIVIDER is used as a divider for the GPMC clock, so it must be programmed to define the correct WAITMONITORINGTIME delay.

Figure 15-56 shows wait behavior during an asynchronous single read access.

Figure 15-56. Wait Behavior During an Asynchronous Single Read Access (GPMCFCLKDivider = 1)

NOTE: The WAIT signal is active low. `GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME = 0b00, or 0b01.`

15.4.4.9.3.1.2 Wait Monitoring During an Asynchronous Write Access

When wait-pin monitoring is enabled for write accesses (`GPMC_CONFIG1_i[21] WAITWRITEMONITORING` bit = 0x1), the WAIT-invalid timing window is defined by the WRACCESSTIME field. WRACCESSTIME must be set so that the wait pin is at a valid state two GPMC clock cycles before WRACCESSTIME completes. The advance pipelining of the two GPMC clock cycles is the result of the internal synchronization requirements for the WAIT signal.

- WAIT monitored as active freezes the CYCLETIME counter. This informs the GPMC that the data bus

is not captured by the external device. The control signals are kept in their current state. The data bus still drives the data.

- WAIT monitored as inactive unfreezes the CYCLETIME counter. This informs that the data bus is correctly captured by the external device. All signals, including the data bus, are controlled according to their related control timing value and to the CYCLETIME counter status.

When a delay larger than two GPMC clock cycles must be observed between wait-pin deassertion time and the effective data write into the external device (including the required GPMC data setup time and the device data setup time), an extra delay can be added between wait-pin deassertion time detection and effective data write time into the external device and the effective unfreezing of the CYCLETIME counter. This extra delay can be programmed in the [GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME fields (i = 0 to 7).

NOTE:

- The WAITMONITORINGTIME parameter does not delay the wait-pin assertion or deassertion detection, nor does it modify the two GPMC clock cycles pipelined detection delay.
 - This extra delay is expressed as a number of GPMC_CLK clock cycles, even though the access is defined as asynchronous, and even though no clock is provided to the external device. Still, [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER is used as a divider for the GPMC clock and so it must be programmed to define the correct WAITMONITORINGTIME delay.
-

15.4.4.9.3.1.3 Wait Monitoring During a Synchronous Read Access

During synchronous accesses with wait-pin monitoring enabled, the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

The WAIT signal can be programmed to apply to the same clock cycle it is captured in. Alternatively, it can be sampled one or two GPMC_CLK cycles ahead of the clock cycle it applies to. This pipelining is applicable to the entire burst access, and to all data phase in the burst access. This WAIT pipelining depth is programmed in the [GPMC_CONFIG1_i\[19:18\]](#) WAITMONITORINGTIME field (where i = 0 to 7), and is expressed as a number of GPMC_CLK clock cycles.

In synchronous mode, when wait-pin monitoring is enabled ([GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bit), the effective access time is a logical AND combination of the RDACCESSTIME timing completion and the WAIT deasserted-state detection.

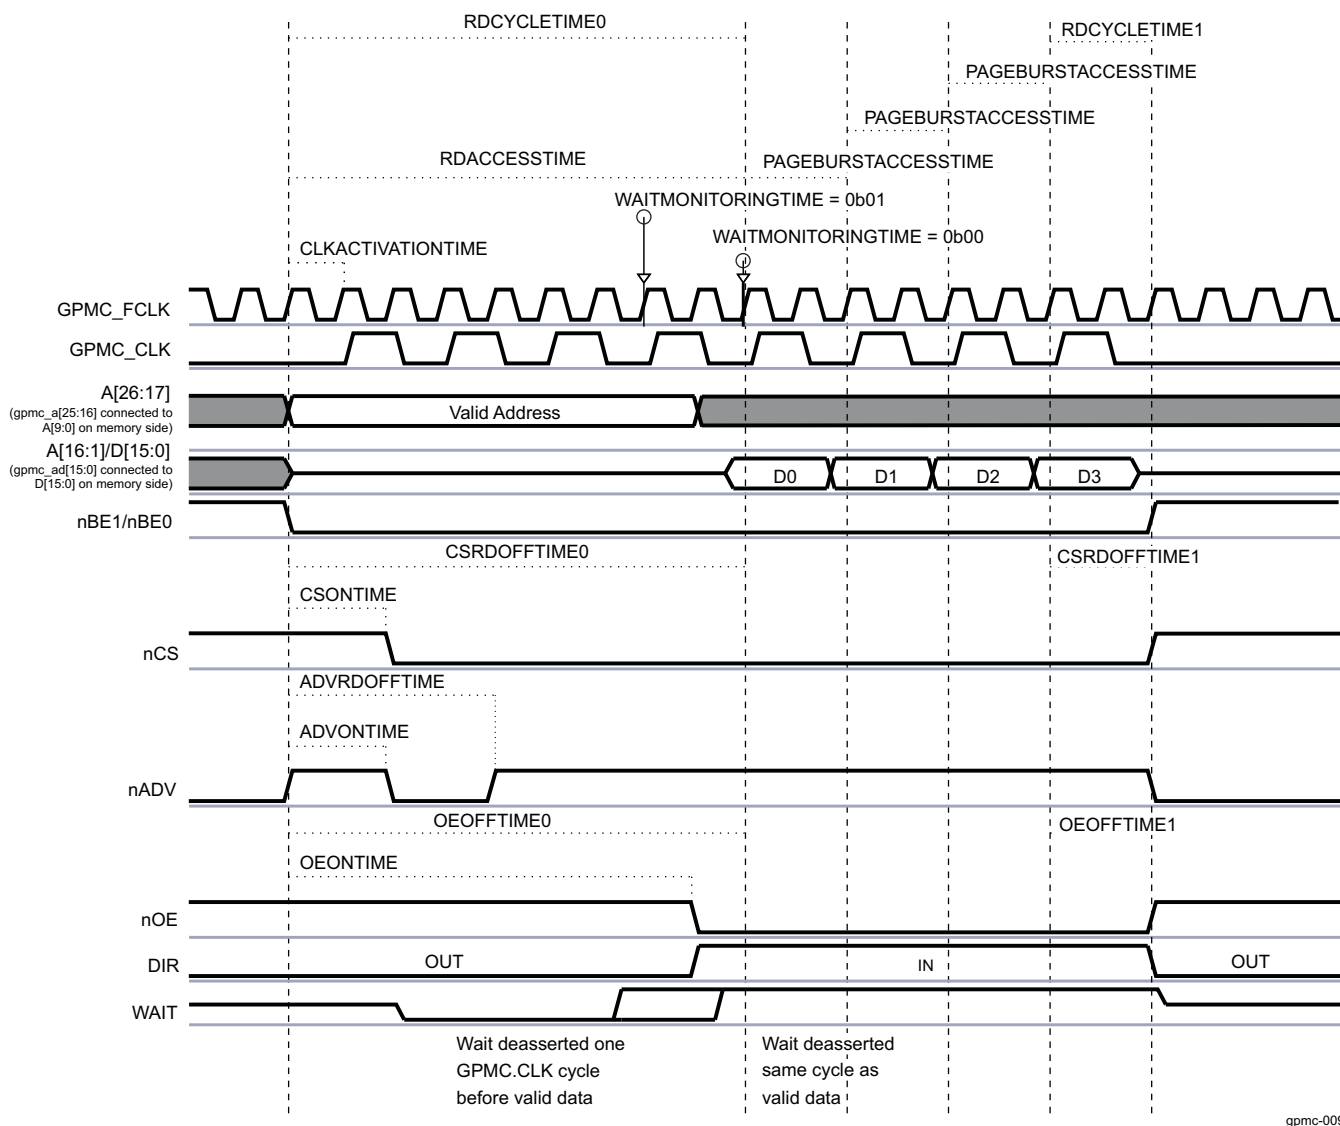

Depending on the programmed WAITMONITORINGTIME value, the wait pin should be at a valid level, either asserted or deasserted:

- In the same clock cycle the data is valid if WAITMONITORINGTIME = 0 (at RDACCESSTIME completion)
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK clock cycles before RDACCESSTIME completion if WAITMONITORINGTIME not equal to 0

Similarly, during a multiple-access cycle (burst mode), the effective access time is a logical AND combination of PAGEBURSTACCESSTIME timing completion and the wait-inactive state. The Wait pipelining depth programming applies to the whole burst access.

- WAIT monitored as active freezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in a lock state), WAIT monitored as active extends the current access time in the burst. Control signals are kept in their current state. The data bus is considered invalid, and no data are captured during this clock cycle.
- WAIT monitored as inactive unfreezes the CYCLETIME counter. For an access within a burst (when the CYCLETIME counter is by definition in lock state), WAIT monitored as inactive completes the current access time and starts the next access phase in the burst. The data bus is considered valid, and data are captured during this clock cycle. In a single access or if this was the last access in a multiple-access cycle, all signals are controlled according to their relative control timing value and the CYCLETIME counter status.

[Figure 15-57](#) shows wait behavior during a synchronous read burst access.

Figure 15-57. Wait Behavior During a Synchronous Read Burst Access

gpmc-009

NOTE: The WAIT signal is active low. WAITMONITORINGTIME = 00, 01.

15.4.4.9.3.1.4 Wait Monitoring During a Synchronous Write Access

During synchronous accesses with wait-pin monitoring enabled (the WAITWRITEMONITORING bit), the wait pin is captured synchronously with GPMC_CLK, using the rising edge of this clock.

If enabled, external wait-pin monitoring can be used in combination with WRACCESSTIME to delay the effective memory device GPMC_CLK capture edge.

Wait-monitoring pipelining depth is similar to synchronous read access:

- At WRACCESSTIME completion if WAITMONITORINGTIME = 0
- In the WAITMONITORINGTIME x (GPMCFCLKDIVIDER + 1) GPMC_FCLK cycles before WRACCESSTIME completion if WAITMONITORINGTIME not equal to 0.

Wait-monitoring pipelining definition applies to whole burst accesses:

- WAIT monitored as active freezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as active indicates that the data

bus is not being captured by the external device. Control signals are kept in their current state. The data bus is kept in its current state.

- WAIT monitored as inactive unfreezes the CYCLETIME counter. For accesses within a burst, when the CYCLETIME counter is by definition in a lock state, WAIT monitored as inactive indicates the effective data capture of the bus by the external device and starts the next access of the burst. In case of a single access or if this was the last access in a multiple access cycle, all signals, including the data bus, are controlled according to their related control timing value and the CYCLETIME counter status.

NOTE: Wait monitoring is supported for all configurations except for `GPMC_CONFIG1_i[19:18]` `WAITMONITORINGTIME = 0x0` (where `i = 0 to 7`) for write bursts with a clock divider of 1 or 2 (`GPMC_CONFIG1_i[1:0]` `GPMCFCLKDIVIDER` field equal to `0x0` or `0x1` respectively).

15.4.4.9.3.1.5 WAIT with NAND Device

For details about the use of the wait pin for communication with a NAND flash external device, see [Section 15.4.4.13.2, NAND Device-Ready Pin](#).

15.4.4.9.3.1.6 Idle Cycle Control Between Successive Accesses

15.4.4.9.3.1.6.1 Bus Turnaround (BUSTURNAROUND)

To prevent data-bus contention, an access that follows a read access to a slow memory/device must be delayed (in other words, control the nCS/nOE de-assertion to data bus in high-impedance delay).

The bus turnaround is a time-out counter starting after nCS or nOE de-assertion time, whichever occurs first, and delays the next access start-cycle time. The counter is programmed through the `GPMC_CONFIG6_i[3:0]` `BUSTURNAROUND` bit field (where `i = 0 to 7`).

After a read access to a chip-select with a non zero `BUSTURNAROUND`, the next access is delayed until the `BUSTURNAROUND` delay completes, if the next access is one of the following:

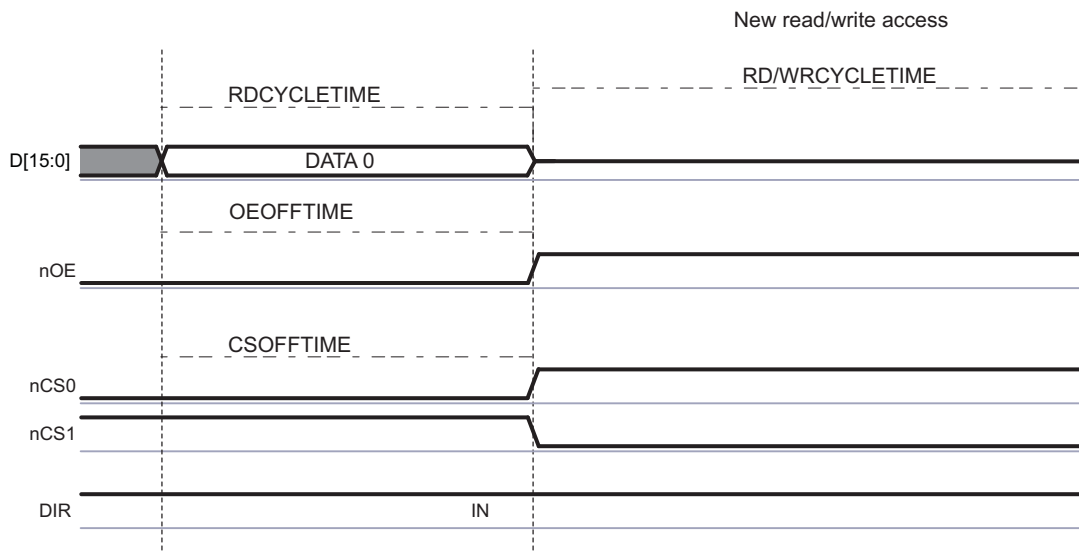

- A write access to any chip-select (same or different from the chip-select data was read from)
- A read access to a different chip-select from the chip-select data was read access from
- A read or write access to a chip-select associated with an address/data-multiplexed device

NOTE: Bus keeping starts after bus turnaround completion so that DIR changes from IN to OUT after bus turnaround. The bus will not have enough time to go into high-impedance even though it could be driven with the same value before bus turnaround timing.

`BUSTURNAROUND` delay runs in parallel with `GPMC_CONFIG6_i[3:0]` `CYCLE2CYCLEDELAY` delays. It should be noted that `BUSTURNAROUND` is a timing parameter for the ending chip-select access while `CYCLE2CYCLEDELAY` is a timing parameter for the following chip-select access. The effective minimum delay between successive accesses is driven by these delay timing parameters and by the access type of the following access. See [Figure 15-58](#) to [Figure 15-60](#).

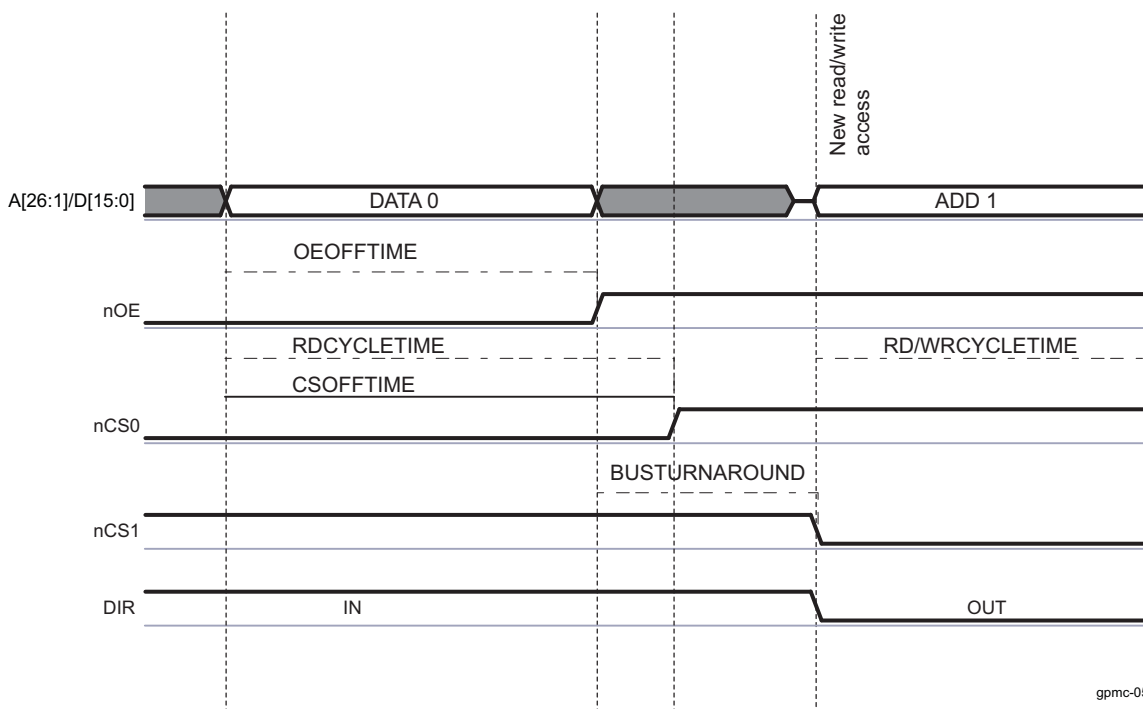

Another way to prevent bus contention is to define an earlier nCS or nOE deassertion time for slow devices or to extend the value of `RDCYCLETIME`. Doing this prevents bus contention, but affects all accesses of this specific chip-select.

Figure 15-58. Read to Read for an Address-Data Multiplexed Device, on Different CS, without Bus Turnaround (nCS0 attached to a fast device)

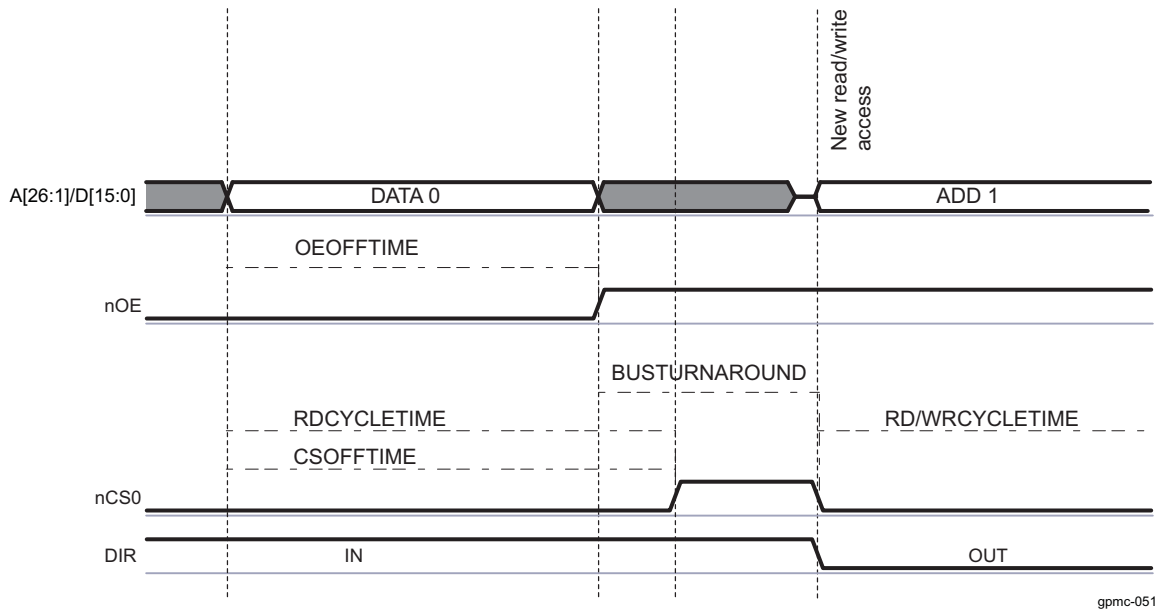

gpmc-049

Figure 15-59. Read to Read / Write for an Address-Data Multiplexed Device, on Different CS, with Bus Turnaround

gpmc-050

Figure 15-60. Read to Read / Write for a Address-Data or AAD-multiplexed device, on the Same CS, with Bus Turnaround

15.4.4.9.3.1.6.2 Idle Cycles Between Accesses to Same Chip-Select (CYCLE2CYCLESAMECSSEN, CYCLE2CYCLEDELAY)

Some devices require a minimum chip-select signal inactive time between accesses. The [GPMC_CONFIG6_i\[7\]](#) CYCLE2CYCLESAMECSSEN bit ($i = 0$ to 7) enables insertion of a minimum number of GPMC_FCLK cycles, defined by the [GPMC_CONFIG6_i\[11:8\]](#) CYCLE2CYCLEDELAY field, between successive accesses of any type (read or write) to the same chip-select.

If CYCLE2CYCLESAMECSSEN is enabled, any subsequent access to the same chip-select is delayed until its CYCLE2CYCLEDELAY completes. The CYCLE2CYCLEDELAY counter starts when CSRDOFFTIME/CSWROFFTIME completes.

The same applies to successive accesses occurring during 32-bit word or burst accesses split into successive single accesses when the single-access mode is used ([GPMC_CONFIG1_i\[30\]](#) READMULTIPLE = 0 or [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE = 0).

All control signals (CS, ADV#/ALE, BE0#/CLE, WE#, and GPMC.CLK) are kept inactive (ADV#/ALE, BE0#/CLE, and GPMC.CLK at low level; and CS, OE#/RE, and WE at high level) during the idle GPMC.FCLK cycles. This prevents back-to-back accesses to the same chip-select without idle cycles between accesses.

15.4.4.9.3.1.6.3 Idle Cycles Between Accesses to Different Chip-Select (CYCLE2CYCLEDIFFCSSEN, CYCLE2CYCLEDELAY)

Because of the pipelined behavior of the system, successive accesses to different chip-selects can occur back-to-back with no idle cycles between accesses. Depending on the control signals (nCS, nADV/ALE, nBE0/CLE, nOE/RE, nWE) assertion and de-assertion timing parameters and on the IC timing parameters, some control signals assertion times may overlap between the successive accesses to different CS. Similarly, some control signals (WE, OE/RE) may not respect required transition times.

To work around the overlapping and to observe the required control-signal transitions, a minimum of CYCLE2CYCLEDELAY inactive cycles is inserted between the access being initiated to this chip-select and the previous access ending for a different chip-select. This applies to any type of access (read or write).

If [GPMC_CONFIG6_i\[6\]](#) CYCLE2CYCLEDIFFCSEN is enabled, the chip-select access is delayed until CYCLE2CYCLEDELAY cycles have expired since the end of a previous access to a different chip-select. CYCLE2CYCLEDELAY count starts at CSRDOFFTIME/CSWROFFTIME completion. All control signals are kept inactive during the idle GPMC_FCLK cycles.

NOTE: CYCLE2CYCLESAMECSEN and CYCLE2CYCLEDIFFCSEN should be set in [GPMC_CONFIG6_i](#) registers to respectively get idle cycles inserted between accesses on this chip-select and after accesses to a different chip-select.

The CYCLE2CYCLEDELAY delay runs in parallel with the BUSTURNAROUND delay. It should be noted that BUSTURNAROUND is a timing parameter defined for the ending chip-select access, whereas CYCLE2CYCLEDELAY is a timing parameter defined for the starting chip-select access. The effective minimum delay between successive accesses is based on the larger delay timing parameter and on access type combination, since bus turnaround does not apply to all access types. See [Section 15.4.4.9.3.1.6.1, Bus Turnaround \(BUSTURNAROUND\)](#) for more details on bus turnaround.

[Table 15-226](#) describes the configuration required for idle cycle insertion.

Table 15-226. Idle Cycle Insertion Configuration

| 1st Access Type | BUSTURN AROUND Timing Parameter | Second Access Type | Chip-Select | Add/Data Multiplexed | CYCLE2 CYCLE SAMECSEN Parameter | CYCLE2 CYCLE DIFFCSEN Parameter | Idle Cycle Insertion Between the Two Accesses |
|-----------------|---------------------------------|--------------------|-------------|----------------------|---------------------------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| R/W | = 0 | R/W | Any | Any | 0 | x | No idle cycles are inserted if the two accesses are well pipelined. |
| R | > 0 | R | Same | Nonmuxed | x | 0 | No idle cycles are inserted if the two accesses are well pipelined. |
| R | > 0 | R | Different | Nonmuxed | 0 | 0 | BUSTURNAROUND cycles are inserted. |
| R | > 0 | R/W | Any | Muxed | 0 | 0 | BUSTURNAROUND cycles are inserted. |
| R | > 0 | W | Any | Any | 0 | 0 | BUSTURNAROUND cycles are inserted. |
| W | > 0 | R/W | Any | Any | 0 | 0 | No idle cycles are inserted if the two accesses are well pipelined. |
| R/W | = 0 | R/W | Same | Any | 1 | x | CYCLE2CYCLEDELAY cycles are inserted. |
| R/W | = 0 | R/W | Different | Any | x | 1 | CYCLE2CYCLEDELAY cycles are inserted. |
| R/W | > 0 | R/W | Same | Any | 1 | x | CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is max (BUSTURNAROUND, CYCLE2CYCLEDELAY). |
| R/W | > 0 | R/W | Different | Any | x | 1 | CYCLE2CYCLEDELAY cycles are inserted. If BTA idle cycles already apply on these two back-to-back accesses, the effective delay is maximum (BUSTURNAROUND, CYCLE2CYCLEDELAY). |

15.4.4.9.3.1.7 Slow Device Support (TIMEPARAGRANULARITY Parameter)

All access-timing parameters can be multiplied by 2 by setting the [GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY bit (where i stands for the GPMC chip-select value, i = 0 to 7). Increasing all access timing parameters allows support of slow devices.

15.4.4.9.3.2 gpmc_io_dir Pin

The gpmc_io_dir pin is used to control I/O direction on the GPMC data bus gpmc_ad[15:0]. Depending on top-level pad multiplexing, this signal can be output and used externally to the device, if required.

The gpmc_io_dir pin is low during transmit (OUT) and high during receive (IN).

For write accesses, the gpmc_io_dir pin stays OUT from start-cycle time to end-cycle time.

For read accesses, the gpmc_io_dir pin goes from OUT to IN at nOE assertion time and stays IN until:

- BUSTURNAROUND is enabled:
 - The gpmc_io_dir pin goes from IN to OUT at end-cycle time plus programmable bus turnaround time.
- BUSTURNAROUND is disabled:
 - After an asynchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 1 GPMC_FCLK cycle or when RDCYCLETIME completes, whichever occurs last.
 - After a synchronous read access, the gpmc_io_dir pin goes from IN to OUT at RDACCESSTIME + 2 GPMC_FCLK cycles or when RDCYCLETIME completes, whichever occurs last.

Because of the bus-keeping feature of the GPMC, after a read or write access and with no other accesses pending, the default value of the gpmc_io_dir pin is OUT (see [Section 15.4.4.10.10, Bus Keeping Support](#)).

In nonmultiplexed devices, the gpmc_io_dir pin stays IN between two successive read accesses to prevent unnecessary toggling (nonmultiplexed 16-bit wide devices support is limited to 2 Kbytes).

15.4.4.9.3.3 Reset

No reset signal is sent to the external memory device by the GPMC. For more information about external-device reset, see [Chapter 3, Power, Reset, and Clock Management](#).

The PRCM module provides an input pin, global_rst_n, to the GPMC:

- The global_rst_n pin is activated during device warm reset and cold reset.
- The global_rst_n pin initializes the internal state-machine and the internal configuration registers.

15.4.4.9.3.4 Write Protect Signal (nWP)

When connected to the attached memory device, the write protect signal can enable or disable the lockdown function of the attached memory.

The gpmc_nwp output pin value is controlled through the [GPMC_CONFIG\[4\]](#) WRITEPROTECT bit, which is common to all CS.

15.4.4.9.3.5 Byte Enable (nBE1/nBE0)

Byte enable signals (nBE1/nBE0) are:

- Valid (asserted or nonasserted according to the incoming system request) from access start to access completion for asynchronous and synchronous single accesses
- Asserted low from access start to access completion for asynchronous and synchronous multiple read accesses
- Valid (asserted or nonasserted, according to the incoming system request) synchronously to each written data for synchronous multiple write accesses

15.4.4.9.4 Error Handling

When an error occurs in the GPMC, the error information is stored in the [GPMC_ERR_TYPE](#) register and the address of the illegal access is stored in the [GPMC_ERR_ADDRESS](#) register. The GPMC only keeps the first error abort information until the [GPMC_ERR_TYPE](#) register is reset. Subsequent accesses that cause errors are not logged until the error is cleared by hardware with the [GPMC_ERR_TYPE\[0\]](#) ERRORVALID bit.

- ERRORNOTSUPPADD occurs when an incoming system request address decoding does not match

any valid chip-select region, or if two chip-select regions are defined as overlapped, or if a register file access is tried outside the valid address range of 1 Kbyte.

- **ERRORNOTSUPPMCMD** occurs when an unsupported command request is decoded at the L3 interconnect interface.
- **ERRORTIMEOUT**: A time-out mechanism prevents the system from hanging. The start value of the 9-bit time-out counter is defined in the [GPMC_TIMEOUT_CONTROL](#) register and enabled with the [GPMC_TIMEOUT_CONTROL\[0\] TIMEOUTENABLE](#) bit. When enabled, the counter starts at start-cycle time until it reaches 0 and data is not responded to from memory, then a time-out error occurs. When data are sent from memory, this counter is reset to its start value. With multiple accesses (asynchronous page mode or synchronous burst mode), the counter is reset to its start value for each data access within the burst.

The GPMC does not generate interrupts on these errors. True abort to the MPU or interrupt generation is handled at interconnect level.

15.4.4.10 Timing Setting

The GPMC offers the maximum flexibility to support various access protocols. Most of the timing parameters of the protocol access used by the GPMC to communicate with attached memories or devices are programmable on a chip-select basis. Assertion and deassertion times of control signals are defined to match the attached memory or device timing specifications and to get maximum performance during accesses. For more information on [GPMC_CLK](#) and [GPMC_FCLK](#) see [Section 15.4.4.10.6, GPMC_CLK](#).

NOTE: In the following sections, the start access time refer to the time at which the access begins.

15.4.4.10.1 Read Cycle Time and Write Cycle Time (RDCYCLETIME / WRCYCLETIME)

The [GPMC_CONFIG5_i\[4:0\] RDCYCLETIME](#) and [GPMC_CONFIG5_i\[12:8\] WRCYCLETIME](#) fields ($i = 0$ to 7) define the address bus and byte enables valid times for read and write accesses. To ensure a correct duty cycle of [GPMC_CLK](#) between accesses, [RDCYCLETIME](#) and [WRCYCLETIME](#) are expressed in [GPMC_FCLK](#) cycles and must be multiples of the [GPMC_CLK](#) cycle. [RDCYCLETIME](#) and [WRCYCLETIME](#) bit fields can be set with a granularity of 1 or 2 through [GPMC_CONFIG1_i\[4\] TIMEPARAGRANULARITY](#).

When either [RDCYCLETIME](#) or [WRCYCLETIME](#) completes, if they are not already deasserted, all control signals ([nCS](#), [nADV/ALE](#), [nOE/RE](#), [nWE](#), and [BE0/CLE](#)) are deasserted to their reset values, regardless of their deassertion time parameters.

An exception to this forced deassertion occurs when a pipelined request to the same chip-select or to a different chip-select is pending. In such a case, it is not necessary to deassert a control signal with deassertion time parameters equal to the cycle-time parameter. This exception to forced deassertion prevents any unnecessary glitches. This requirement also applies to [BE](#) signals, thus avoiding an unnecessary [BE](#) glitch transition when pipelining requests.

NOTE: All control signals ([CS](#), [ADV#/ALE](#), [BE0#/CLE](#), [WE#](#), and [GPMC.CLK](#)) are kept inactive ([ADV#/ALE](#), [BE0#/CLE](#), and [GPMC.CLK](#) at low level; and [CS](#), [OE#/RE](#), and [WE](#) at high level) during the idle [GPMC.FCLK](#) cycles.

If no inactive cycles are required between successive accesses to the same or to a different chip-select ([GPMC_CONFIG6_i\[7\] CYCLE2CYCLESAMECSSEN = 0](#) or [GPMC_CONFIG6_i\[6\] CYCLE2CYCLEDIFFCSSEN = 0](#), where $i = 0$ to 7), and if assertion-time parameters associated with the pipelined access are equal to 0, asserted control signals ([nCS](#), [nADV/ALE](#), [nBE0/CLE](#), [nWE](#), and [nOE/RE](#)) are kept asserted. This applies to any read/write to read/write access combination.

If inactive cycles are inserted between successive accesses, that is, [CYCLE2CYCLESAMECSSEN = 1](#) or [CYCLE2CYCLEDIFFCSSEN = 1](#), the control signals are forced to their respective default reset values for the number of [GPMC_FCLK](#) cycles defined in [CYCLE2CYCLEDELAY](#).

15.4.4.10.2 nCS: Chip-Select Signal Control Assertion/Deassertion Time (CSONTIME / CSRDOFFTIME /

CSWROFFTIME / CSEXTRADELAY)

The [GPMC_CONFIG2_i\[3:0\]](#) CSONTIME field (where $i = 0$ to 7) defines the nCS signal-assertion time relative to the start access time. It is common for read and write accesses.

[GPMC_CONFIG2_i\[12:8\]](#) CSRDOFFTIME (read access) and [GPMC_CONFIG2_i\[20:16\]](#) CSWROFFTIME (write access) bit fields define the nCS signal deassertion time relative to start access time.

CSONTIME, CSRDOFFTIME and CSWROFFTIME parameters are applicable to synchronous and asynchronous modes. CSONTIME can be used to control an address and byte enable setup time before chip-select assertion. CSRDOFFTIME and CSWROFFTIME can be used to control an address and byte enable hold time after chip-select deassertion.

nCS signal transitions as controlled through CSONTIME, CSRDOFFTIME, and CSWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the [GPMC_CONFIG2_i\[7\]](#) CSEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on the nCS assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. CSEXTRADELAY is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, CSEXTRADELAY applies to all parameters controlling nCS transitions.

The CSEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than the nCS signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.10.3 nADV/ALE: Address Valid/Address Latch Enable Signal Control Assertion/Deassertion Time (ADVONTIME / ADVRDOFFTIME / ADVWROFFTIME / ADVEXTRADELAY/ADVAADMUXONTIME/ADVAADMUXRDOFFTIME/ADVAADMUXWROFFTIME)

The [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field (where $i = 0$ to 7) defines the nADV/ALE signal-assertion time relative to start access time. It is common to read and write accesses.

[GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME (read access) and [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME (write access) bit fields define the nADV/ALE signal-deassertion time relative to start access time.

ADVONTIME can be used to control an address and byte enable valid setup time control before nADV/ALE assertion. ADVRDOFFTIME and ADVWROFFTIME can be used to control an address and byte enable valid hold time control after nADV/ALE de-assertion. ADVRDOFFTIME and ADVWROFFTIME are applicable to both synchronous and asynchronous modes.

nADV/ALE signal transitions as controlled through ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME can be delayed by half a GPMC_FCLK period by enabling the [GPMC_CONFIG3_i\[7\]](#) ADVEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nADV/ALE assertion and deassertion time to guarantee proper setup and hold time relative to GPMC_CLK. The ADVEXTRADELAY configuration parameter is especially useful in configurations where GPMC_CLK and GPMC_FCLK have the same frequency, but can be used for all GPMC configurations. If enabled, ADVEXTRADELAY applies to all parameters controlling nADV/ALE transitions.

ADVEXTRADELAY must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the RDCYCLETIME and WRCYCLETIME bit fields to be greater than nADV/ALE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

[GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME, [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME, and [GPMC_CONFIG3_i\[30:28\]](#) ADVAADMUXWROFFTIME parameters have the same functions as ADVONTIME, ADVRDOFFTIME, and ADVWROFFTIME, but apply to the first address phase in the AAD-multiplexed protocol. It is the user responsibility to make sure ADVAADMUXxxOFFTIME is programmed to a value lower than or equal to ADVxxOFFTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. ADVAADMUXxxOFFTIME can be programmed to the same value as ADVONTIME if no high nADV pulse is needed between the two AAD-mux address phases, which is the typical case in synchronous mode. In this configuration, nADV is kept low until it reaches the correct ADVxxOFFTIME.

See [Section 15.4.4.13, NAND Access Description](#) for more details on ADVONTIME, ADVRDFFTIME, ADVWROFFTIME, and ADVAADMUXRDFFTIME, ADVAADMUXWROFFTIME usage for CLE and ALE (Command / Address Latch Enable) usage for a NAND Flash interface.

15.4.4.10.4 nOE/nRE: Output Enable / Read Enable Signal Control Assertion / Deassertion Time (OEONTIME / OEOFFTIME / OEEXTRADELAY / OEAADMUXONTIME / OEAADMUXOFFTIME)

The [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field (where i = 0 to 7) defines the nOE/nRE signal assertion time relative to start access time. It is applicable only to read accesses.

The [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME field defines the nOE/nRE signal deassertion time relative to start access time. It is applicable only to read accesses. nOE/nRE is not asserted during a write cycle.

OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME parameters are applicable to synchronous and asynchronous modes. OEONTIME can be used to control an address and byte enable valid setup time control before nOE/nRE assertion. OEOFFTIME can be used to control an address and byte enable valid hold time control after nOE/nRE assertion.

OEAADMUXONTIME and OEAADMUXOFFTIME parameters have the same functions as OEONTIME and OEOFFTIME, but apply to the first OE assertion in the AAD-multiplexed protocol for a read phase, or to the only OE assertion for a write phase. It is the user responsibility to make sure OEAADMUXOFFTIME is programmed to a value lower than OEONTIME. Functionality in AAD-mux mode is undefined if the settings do not comply with this requirement. OEAADMUXOFFTIME shall never be equal to OEONTIME because the AAD-mux protocol requires a second address phase with the nOE signal deasserted before nOE can be asserted again to define a read command.

The nOE/RE signal transitions as controlled through OEONTIME, OEOFFTIME, OEAADMUXONTIME and OEAADMUXOFFTIME can be delayed by half a GPMC_FCLK period by enabling the [GPMC_CONFIG4_i\[7\]](#) OEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nOE/RE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, OEEXTRADELAY applies to all parameters controlling nOE/nRE transitions.

OEEXTRADELAY must be used carefully, to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program RDCYCLETIME and WRCYCLETIME to be greater than nOE/RE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

NOTE: When the GPMC generates a read access to an address-/data-multiplexed device, it drives the address bus until nOE assertion time.

15.4.4.10.5 nWE: Write Enable Signal Control Assertion / Deassertion Time (WEONTIME / WEOFFTIME / WEEXTRADELAY)

The [GPMC_CONFIG4_i\[19:16\]](#) WEONTIME field (where i = 0 to 7) defines the nWE signal-assertion time relative to start access time. The [GPMC_CONFIG4_i\[28:24\]](#) WEOFFTIME field defines the nWE signal-deassertion time relative to start access time. These bit fields only apply to write accesses. nWE is not asserted during a read cycle.

WEONTIME can be used to control an address and byte enable valid setup time control before nWE assertion. WEOFFTIME can be used to control an address and byte enable valid hold time control after nWE assertion.

nWE signal transitions as controlled through WEONTIME, and WEOFFTIME can be delayed by half a GPMC_FCLK period by enabling the [GPMC_CONFIG4_i\[23\]](#) WEEXTRADELAY bit. This half of a GPMC_FCLK period provides more granularity on nWE assertion and deassertion time to guaranty proper setup and hold time relative to GPMC_CLK. If enabled, WEEXTRADELAY applies to all parameters controlling nWE transitions.

The WEEXTRADELAY bit must be used carefully to avoid control-signal overlap between successive accesses to different chip-selects. This implies the need to program the WRCYCLETIME bit field to be greater than the nWE signal-deassertion time, including the extra half-GPMC_FCLK-period delay.

15.4.4.10.6 GPMC_CLK

GPMC_CLK is the external clock provided to the attached synchronous memory or device.

- The GPMC_CLK clock frequency is the GPMC_FCLK functional clock frequency divided by 1, 2, 3, or 4, depending on the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER bit field (where $i = 0$ to 7), with a guaranteed 50-percent duty cycle.
- The GPMC_CLK clock is only activated when the access in progress is defined as synchronous (read or write access).
- The [GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME field ($i = 0$ to 7) defines the number of GPMC_FCLK cycles from start access time to GPMC_CLK activation.
- The GPMC_CLK clock is stopped when cycle time completes and is asserted low between accesses.
- The GPMC_CLK clock is kept low when access is defined as asynchronous.

CAUTION

When cycle time completes, the GPMC_CLK may be high because of the GPMCFCLKDIVIDER bit field. To ensure correct stoppage of the GPMC_CLK clock within the 50-percent required duty cycle, it is the user's responsibility to extend the RDCYCLETIME or WRCYCLETIME value.

NOTE: To ensure a correct external clock cycle, the following rules must be applied:

- $(RDCYCLETIME \text{ CLKACTIVATIONTIME})$ must be a multiple of $(GPMCFCLKDIVIDER + 1)$.
- The PAGEBURSTACCESSTIME value must be a multiple of $(GPMCFCLKDIVIDER + 1)$.

15.4.4.10.7 GPMC_CLK and Control Signals Setup and Hold

Control-signal transition (assertion and deassertion) setup and hold values with respect to the GPMC_CLK edge can be controlled in the following ways:

- For the GPMC_CLK signal, the [GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME field ($i = 0$ to 7) allows setup and hold control of control-signal assertion time.
- The use of a divided GPMC_CLK allows setup and hold control of control-signal assertion and deassertion times.
- When GPMC_CLK runs at the GPMC_FCLK frequency so that GPMC_CLK edge and control-signal transitions refer to the same GPMC_FCLK edge, the control-signal transitions can be delayed by half of a GPMC_FCLK period to provide minimum setup and hold times. This half-GPMC_FCLK delay is enabled with the CSEXTRADELAY, ADVEXTRADELAY, OEEXTRADELAY, or WEEXTRADELAY parameter. This delay must be used carefully to prevent control-signal overlap between successive accesses to different chip-selects. This implies that the RDCYCLETIME and WRCYCLETIME are greater than the last control-signal deassertion time, including the extra half-GPMC_FCLK cycle.

15.4.4.10.8 Access Time (RDACCESSTIME / WRACCESSTIME)

The read access time and write access time durations can be programmed independently through [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME and [GPMC_CONFIG6_i\[28:24\]](#) WRACCESSTIME ($i = 0$ to 7). This allows nOE and GPMC data capture timing parameters to be independent of nWE and memory device data capture timing parameters. RDACCESSTIME and WRACCESSTIME bit fields can be set with a granularity of 1 or 2 through [GPMC_CONFIG1_i\[4\]](#) TIMEPARAGRANULARITY.

15.4.4.10.8.1 Access Time on Read Access

In asynchronous read mode, for single and paged accesses, [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME field ($i = 0$ to 7) defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge used for the first data capture. RDACCESSTIME must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached memory device.

In synchronous read mode, for single or burst accesses, RDACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_FCLK rising edge corresponding to the GPMC_CLK rising edge used for the first data capture.

GPMC_CLK which is sent to the memory device for synchronization with the GPMC controller, is internally retimed to correctly latch the returned data. GPMC_CONFIG5_i[4:0] RDCYCLETIME must be greater than RDACCESSTIME in order to let the GPMC latch the last return data using the internally retimed GPMC_CLK.

The external WAIT signal can be used in conjunction with RDACCESSTIME to control the effective GPMC data-capture GPMC_FCLK edge on read access in both asynchronous mode and synchronous mode. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

15.4.4.10.8.2 Access Time on Write Access

In asynchronous write mode, the GPMC_CONFIG6_i[28:24] WRACCESSTIME timing parameter is not used to define the effective write access time. Instead, it is used as a WAIT invalid timing window, and must be set to a correct value so that the gpmc_wait pin is at a valid state two GPMC_CLK cycles before WRACCESSTIME completes. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

In synchronous write mode, for single or burst accesses, WRACCESSTIME defines the number of GPMC_FCLK cycles from start access time to the GPMC_CLK rising edge used by the memory device for the first data capture.

The external WAIT signal can be used in conjunction with WRACCESSTIME to control the effective memory device data capture GPMC_CLK edge for a synchronous write access. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

15.4.4.10.9 Page Burst Access Time (PAGEBURSTACCESSTIME)

GPMC_CONFIG5_i[27:24] PAGEBURSTACCESSTIME bit field (i = 0 to 7) can be set with a granularity of 1 or 2 through GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY.

15.4.4.10.9.1 Page Burst Access Time on Read Access

In asynchronous page read mode, the delay between successive word captures in a page is controlled through the PAGEBURSTACCESSTIME bit field. The PAGEBURSTACCESSTIME parameter must be programmed to the rounded greater value (in GPMC_FCLK cycles) of the read access time of the attached device.

In synchronous burst read mode, the delay between successive word captures in a burst is controlled through the PAGEBURSTACCESSTIME field.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective GPMC data capture GPMC_FCLK edge on read access. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

15.4.4.10.9.2 Page Burst Access Time on Write Access

Asynchronous page write mode is not supported. PAGEBURSTACCESSTIME is irrelevant in this case.

In synchronous burst write mode, PAGEBURSTACCESSTIME controls the delay between successive memory device word captures in a burst.

The external WAIT signal can be used in conjunction with PAGEBURSTACCESSTIME to control the effective memory-device data capture GPMC_CLK edge in synchronous write mode. For details about wait monitoring, see [Section 15.4.4.9.3.1, Chip-Select Base Address and Region Size](#).

15.4.4.10.10 Bus Keeping Support

At the end-cycle time of a read access, if no other access is pending, the GPMC drives the bus with the last data read after RDCYCLETIME completion time to prevent bus floating and reduce power consumption.

After a write access, if no other access is pending, the GPMC keeps driving the data bus after WRCYCLETIME completes with the same data to prevent bus floating and power consumption.

15.4.4.11 NOR Access Description

For each chip-select configuration, the read access can be specified as either asynchronous or synchronous access through the [GPMC_CONFIG1_i\[29\]](#) READTYPE bit ($i = 0$ to 7). For each chip-select configuration, the write access can be specified as either synchronous or asynchronous access through the [GPMC_CONFIG1_i\[27\]](#) WRITETYPE bit ($i = 0$ to 7).

Asynchronous and synchronous read and write access time and related control signals are controlled through timing parameters that refer to GPMC_FCLK. The primary difference of synchronous mode is the availability of a configurable clock interface (GPMC_CLK) to control the external device. Synchronous mode also affects data-capture and wait-pin monitoring schemes in read access.

For details about asynchronous and synchronous access, see the descriptions of GPMC_CLK, RdAccessTime, WrAccessTime, and wait-pin monitoring.

For more information about timing-parameter settings, see the sample timing diagrams in this chapter.

NOTE: The address bus and nBE[1:0] are fixed for the duration of a synchronous burst read access, but they are updated for each beat of an asynchronous page-read access.

15.4.4.11.1 Asynchronous Access Description

This section describes:

- Asynchronous single-read operation on an address/data multiplexed device
- Asynchronous single write operation on an address/data-multiplexed device
- Asynchronous single read operation on an AAD-multiplexed device
- Asynchronous single write operation on an AAD-multiplexed device
- Asynchronous multiple (page) read operation on a non-multiplexed device

In asynchronous operations GPMC_CLK is not provided outside the GPMC and is kept low.

15.4.4.11.1.1 Access on Address/Data Multiplexed Devices

15.4.4.11.1.1.1 Asynchronous Single-Read Operation on an Address/Data Multiplexed Device

Figure 15-61 shows an asynchronous single read operation on an address/data-multiplexed device.

Figure 15-61. Asynchronous Single Read on an Address/Data-Multiplexed Device

See Section 15.4.5.6.1, *GPMC Timing Parameters Formulas* for formulas to calculate timing parameters.

Table 15-258 lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see Section 15.4.4.9.2.3, *Address/Data-Multiplexing Interface*.

Address bits (A[16:1] from a GPMC perspective, A[15:0] from an external device perspective) are placed on the address/data bus, and the remaining address bits gpmc_a[25:16] are placed on the address bus. The address phase ends at nOE assertion, when the DIR signal goes from OUT to IN.

- Chip-select signal nCS:
 - nCS assertion time is controlled by the `GPMC_CONFIG2_i[3:0]` CS ONTIME field. It controls the address setup time to nCS assertion.
 - nCS deassertion time is controlled by the `GPMC_CONFIG2_i[12:8]` CSRD OFFTIME field. It controls the address hold time from nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the `GPMC_CONFIG3_i[3:0]` ADV ONTIME field.
 - nADV deassertion time is controlled by the `GPMC_CONFIG3_i[12:8]` ADV RD OFFTIME field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the `GPMC_CONFIG4_i[3:0]` OE ONTIME field.

- nOE deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\] OEOFFTIME](#) field.
- Read data is latched when RDACCESSTIME completes. Access time is defined in the [GPMC_CONFIG5_i\[20:16\] RDACCESSTIME](#) field.
- Direction signal DIR: DIR goes from OUT to IN at the same time that nOE is asserted.
- The end of the access is defined by the [GPMC_CONFIG5_i\[4:0\] RDCYCLETIME](#) parameter.

In the GPMC, when a 16-bit wide device is attached to the controller, a 32-bit word write access is split into two 16-bit word write accesses. For more information about GPMC access size and type adaptation, see [Section 15.4.4.11.5, System Burst Versus External Device Burst Support](#).

Between two successive accesses, if an nCS pulse is needed:

- The [GPMC_CONFIG6_i\[11:8\] CYCLE2CYCLEDELAY](#) field can be programmed with [GPMC_CONFIG6_i\[7\] CYCLE2CYCLESAMECSEN](#) enabled.
- The CSWROFFTIME and CSONTIME parameters also allow a chip-select pulse, but this affects all other types of access.

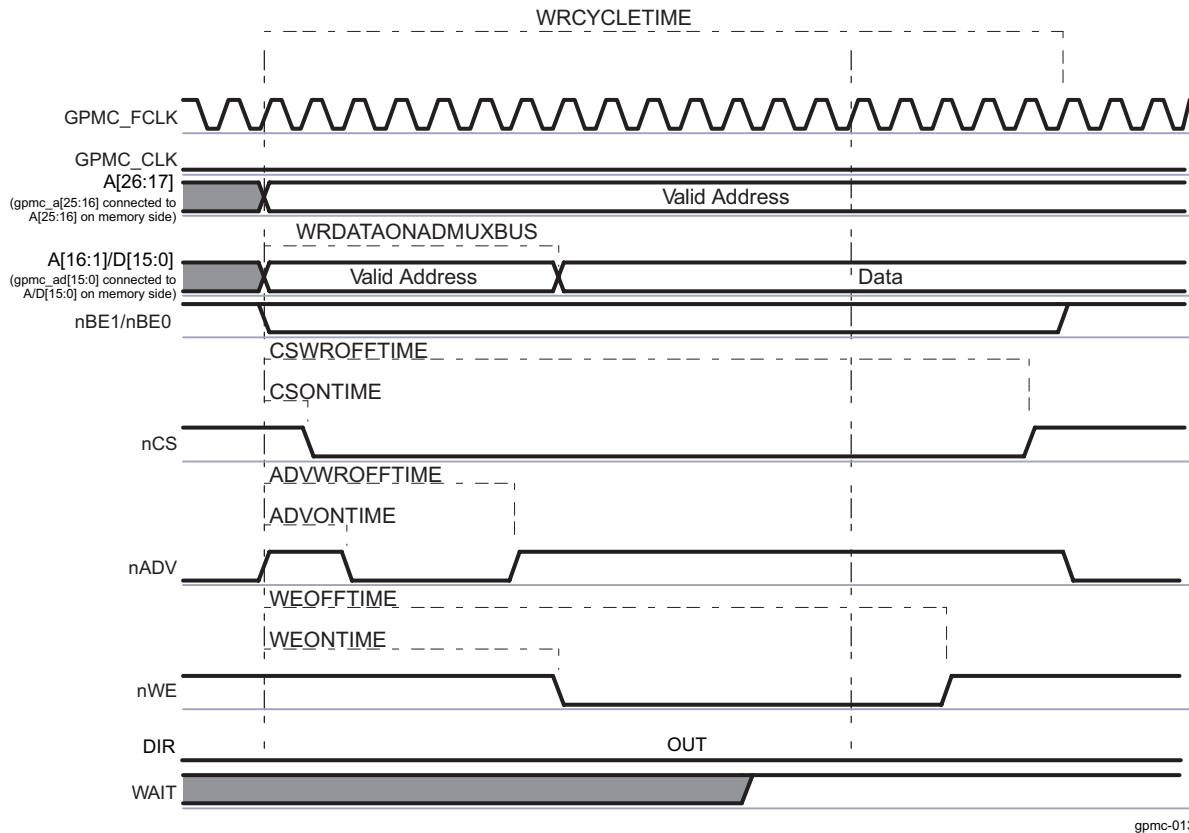

Figure 15-62. Two Asynchronous Single Read Accesses on an Address/Data Multiplexed Device (32-bit read split into 2 x 16-bit read)

gpmc-044

15.4.4.11.1.2 Asynchronous Single Write Operation on an Address/Data-Multiplexed Device

Figure 15-63 shows an asynchronous single write operation on an address/data-multiplexed device.

Figure 15-63. Asynchronous Single Write on an Address/Data-Multiplexed Device

See [Section 15.4.5.6.1, GPMC Timing Parameters Formulas](#) for formulas to calculate timing parameters.

[Table 15-258](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an address/data-multiplexed device, it drives the address bus until nWE assertion time. For more information, see [Section 15.4.4.9.2.3, Address/Data-Multiplexing Interface](#).

The nCS, and nADV signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

- Write enable signal nWE:
 - nWE assertion indicates a write cycle.
 - nWE assertion time is controlled by the [GPMC_CONFIG4_i\[19:16\] WEONTIME](#) field.
 - nWE deassertion time is controlled by the [GPMC_CONFIG4_i\[28:24\] WEOFFTIME](#) field.
- Direction signal DIR: DIR signal is OUT during the entire access.
- The end of the access is defined by the [GPMC_CONFIG5_i\[12:8\] WRCYCLETIME](#) parameter.

Address bits A[16:1] (GPMC point of view) are placed on the address/data bus at the start of cycle time, and the remaining address bits A[26:17] are placed on the address bus.

Data is driven on the address/data bus at a [GPMC_CONFIG6_i\[19:16\] WRDATAONADMUXBUS](#) time.

NOTE: Write multiple access in asynchronous mode is not supported. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

After a write operation, if no other access (read or write) is pending, the data bus keeps its previous value. See [Section 15.4.4.10.10](#), *Bus Keeping Support*.

15.4.4.11.1.1.3 Asynchronous Multiple (Page) Write Operation on an Address/Data-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for address/data-multiplexed devices.

If `GPMC_CONFIG1_i[28]` `WRITEMULTIPLE` is enabled (0x1) with `GPMC_CONFIG1_i[27]` `WRITETYPE` as asynchronous (0x0), the GPMC processes single asynchronous accesses.

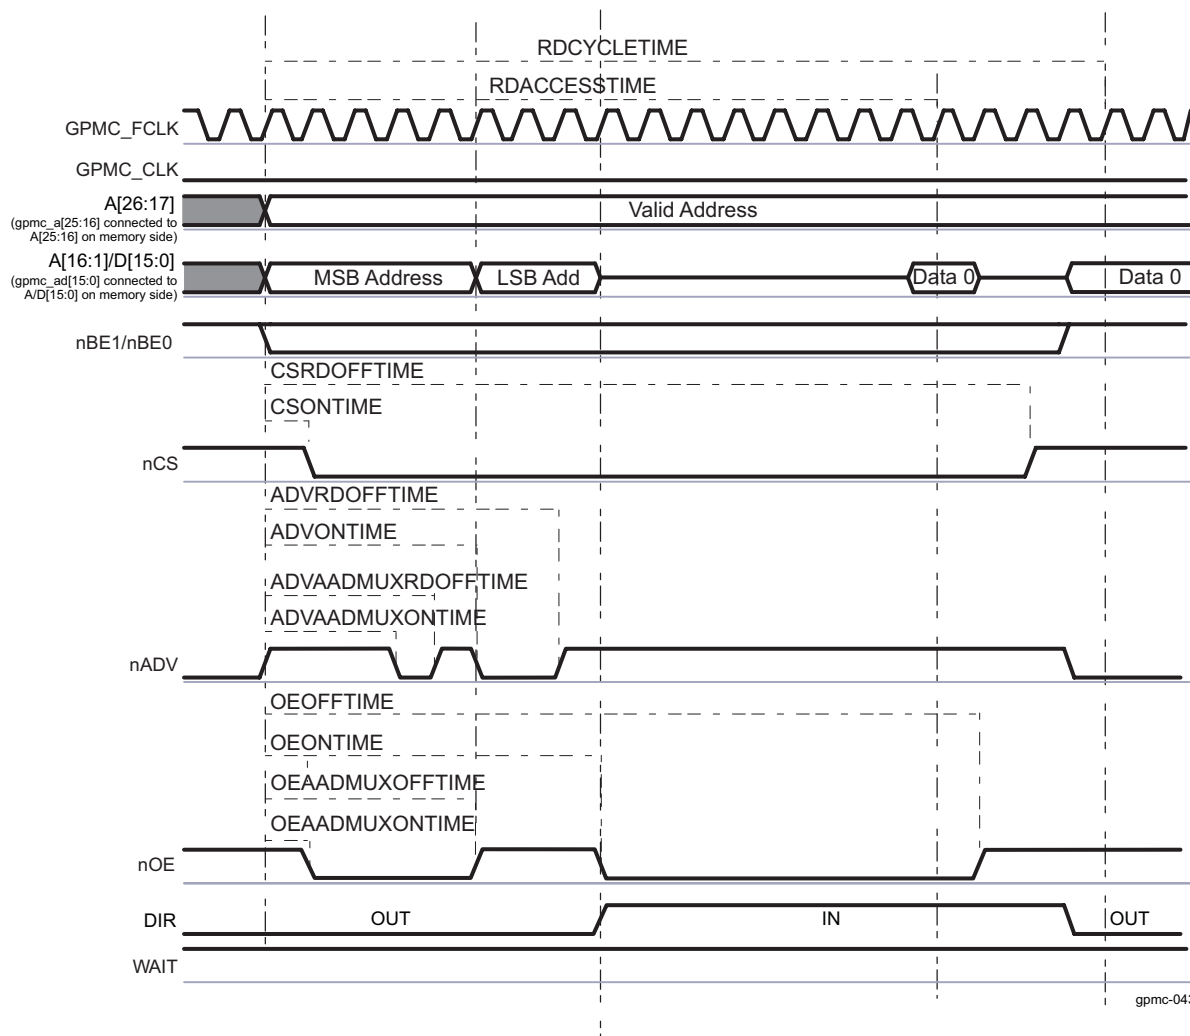

For accesses on non-multiplexed devices refer to [Section 15.4.4.11.3](#), *Asynchronous and Synchronous Accesses in Nonmultiplexed Mode*.

15.4.4.11.1.2 Access on Address/Address/Data Multiplexed Devices

15.4.4.11.1.2.1 Asynchronous Single Read Operation on an AAD-Multiplexed Device

Figure 15-64 shows an asynchronous single read operation on an AAD-multiplexed device.

Figure 15-64. Asynchronous Single Read on an AAD-Multiplexed Device

See [Section 15.4.5.6.1, GPMC Timing Parameters Formulas](#) for formulas to calculate timing parameters.

[Table 15-258](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a read access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The first address phase ends at the first nOE deassertion time. The second phase for LSB address is qualified with nOE driven high. The second address phase ends at the second nOE assertion time, when the DIR signal goes from OUT to IN.

The nCS, and DIR signals are controlled in the same way as for asynchronous single read operation on an address/data-multiplexed device.

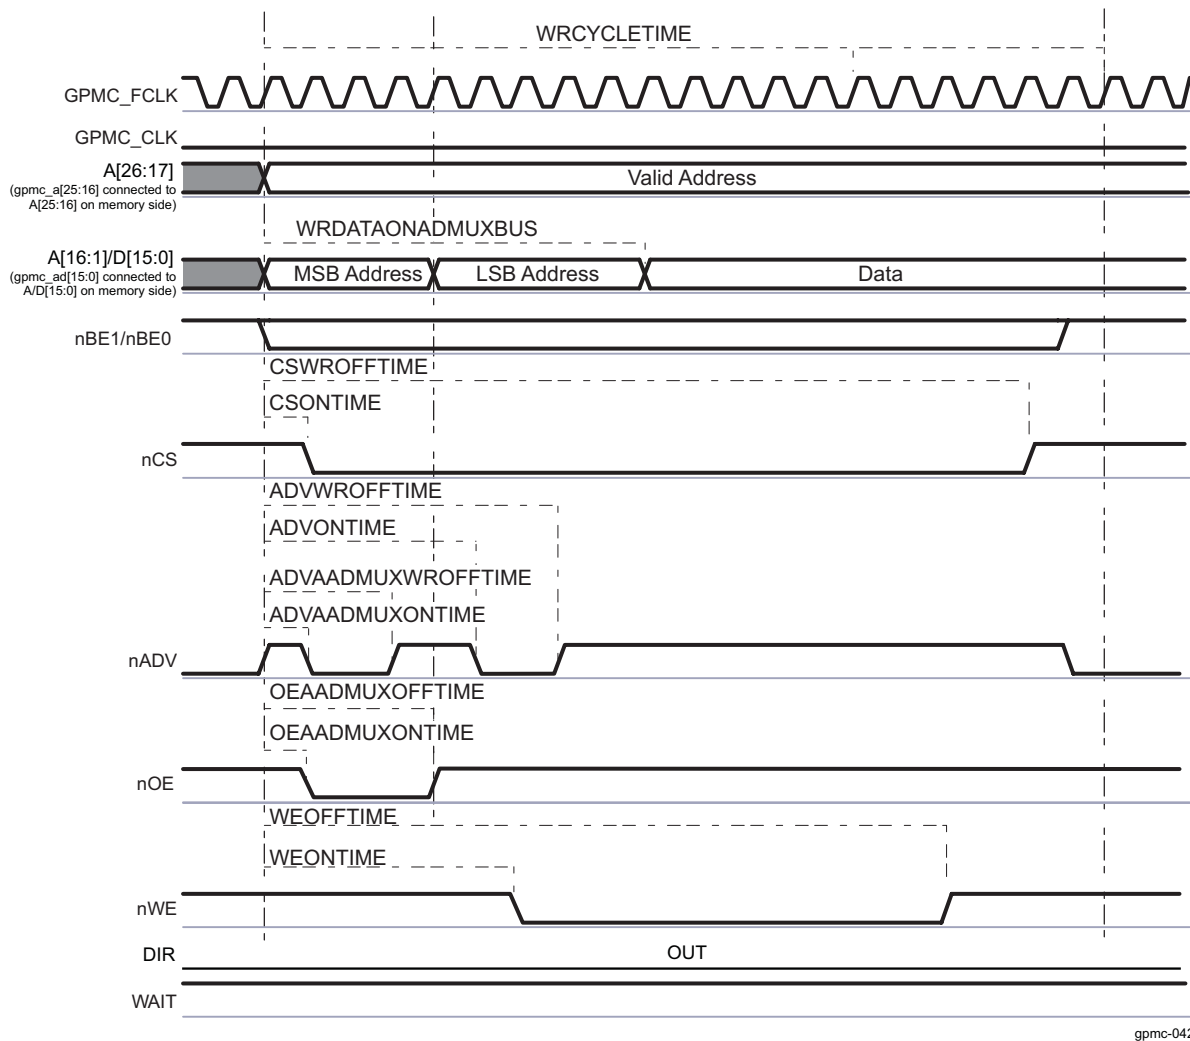

- Address valid signal nADV. nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\] ADVAADMUXONTIME](#) field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[26:24\] ADVAADMUXRDOFFTIME](#) field.

- nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
- nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME field.
- Output Enable signal nOE. nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME field.
 - nOE first deassertion time is controlled by the [GPMC_CONFIG3_i\[15:13\]](#) OEAADMUXOFFTIME field.
 - nOE second assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field.
 - nOE second deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME field.

15.4.4.11.1.2 Asynchronous Single Write Operation on an AAD-Multiplexed Device

Figure 15-65 shows an asynchronous single write operation on an AAD-multiplexed device.

Figure 15-65. Asynchronous Single Write on an AAD-Multiplexed Device

gpmc-042

See [Section 15.4.5.6.1, GPMC Timing Parameters Formulas](#) for formulas to calculate timing parameters.

[Table 15-258](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single write mode.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, nWE, and DIR signals are controlled in the same way as for asynchronous single write operation on an address/data-multiplexed device. See [Table 15-249](#).

- Address valid signal nADV is asserted and deasserted twice during a write transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[30:28\]](#) ADVAADMUXWROFFTIME field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME field.
- Output Enable signal nOE is asserted during the address phase of a write transaction:
 - nOE assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME field.
 - nOE deassertion time is controlled by the [GPMC_CONFIG3_i\[15:13\]](#) OEAADMUXOFFTIME field.

The address bits for the first address phase are driven onto the data bus until nOE deassertion. Data is driven onto the address/data bus at the clock edge defined by the [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS parameter.

15.4.4.11.1.2.3 Asynchronous Multiple (Page) Read Operation on an AAD-Multiplexed Device

Write multiple (page) access in asynchronous mode is not supported for AAD-multiplexed devices.

If [GPMC_CONFIG1_i\[28\]](#) WRITEMULTIPLE is enabled (0x1) with [GPMC_CONFIG1_i\[27\]](#) WRITETYPE as asynchronous (0x0), the GPMC processes single asynchronous accesses.

For accesses on non-multiplexed devices refer to [Section 15.4.4.11.3](#), *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

15.4.4.11.2 Synchronous Access Description

This section details read and write synchronous accesses on address/data multiplexed. All information in this section can be applied to any type of memory - non-multiplexed, address and data multiplexed or AAD-multiplexed - with a difference limited to the address phase. For accesses on non-multiplexed devices refer to [Section 15.4.4.11.3](#), *Asynchronous and Synchronous Accessed in Nonmultiplexed Mode*.

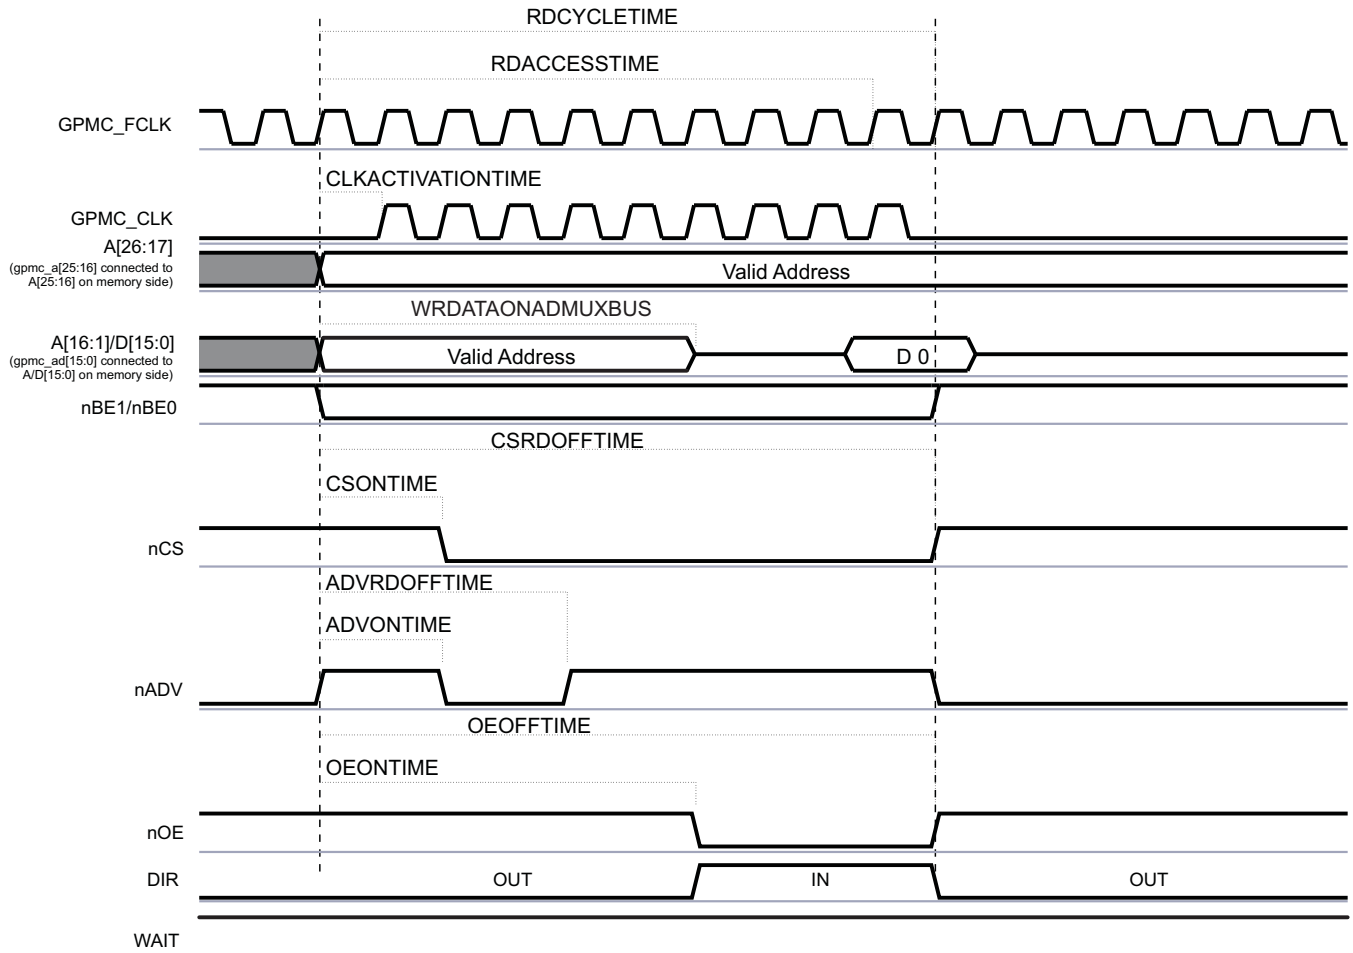

In synchronous operations:

- The GPMC_CLK clock is provided outside the GPMC when accessing the memory device.
- The GPMC_CLK clock is derived from the GPMC_FCLK clock using the [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER field. In the following section i stands for the chip-select number, i = 0 to 7.
- The [GPMC_CONFIG1_i\[26:25\]](#) CLKACTIVATIONTIME field specifies that the GPMC_CLK is provided outside the GPMC 0, 1, or 2 GPMC_FCLK cycles after start access time until RDCYCLETIME or WRCYCLETIME completion.

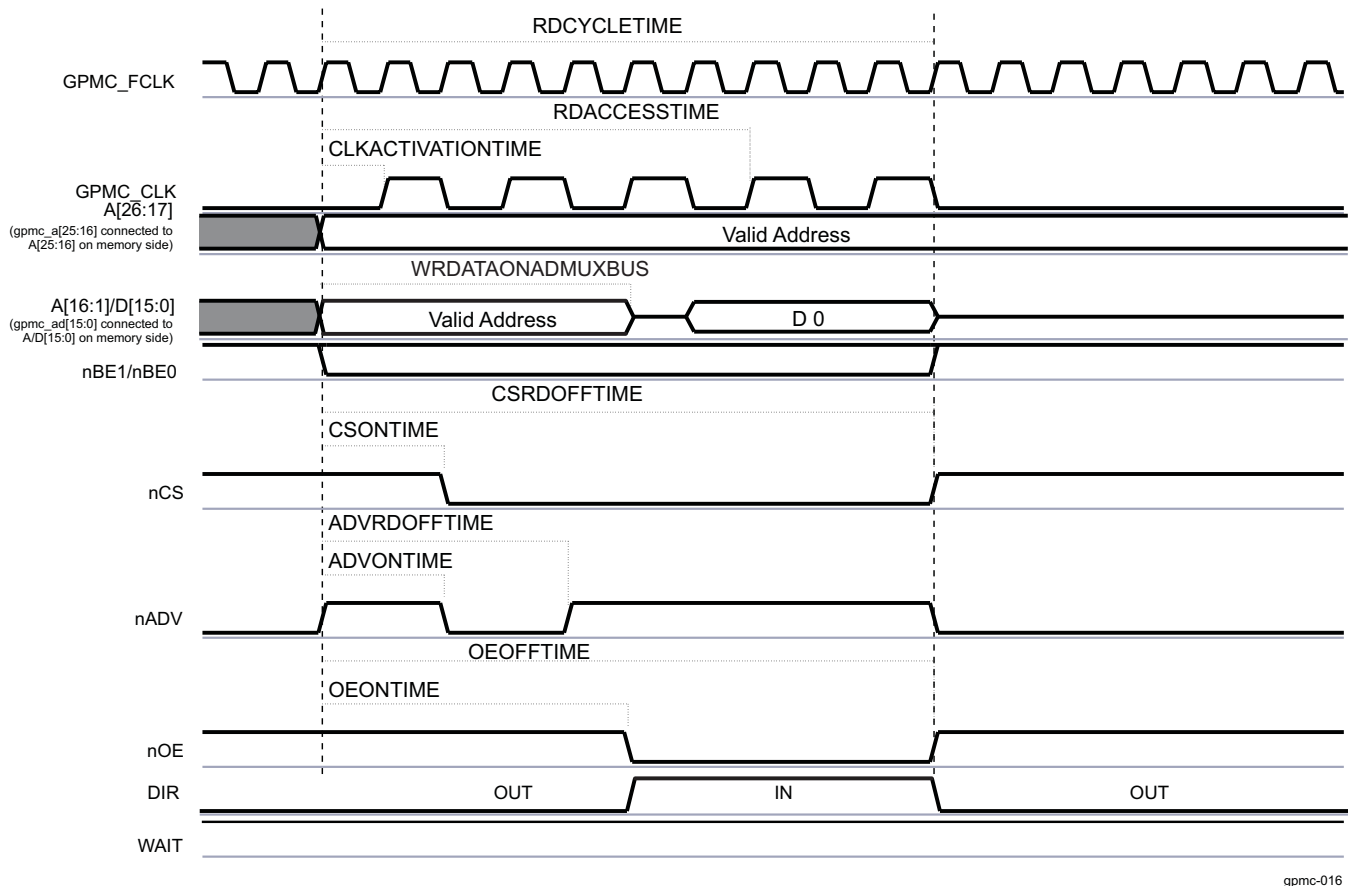

15.4.4.11.2.1 Synchronous Single Read

[Figure 15-66](#) and [Figure 15-67](#) show a synchronous single-read operation with GPMCFCLKDIVIDER equal to 0 and 1, respectively.

Figure 15-66. Synchronous Single Read (GPMCFCLKDIVIDER = 0)

gpmc-015

Figure 15-67. Synchronous Single Read (GPMCFCLKDIVIDER = 1)

gpmc-016

See [Section 15.4.5.6.1, GPMC Timing Parameters Formulas](#) for formulas to calculate timing parameters.

[Table 15-258](#) lists the timing bit fields to set up in order to configure the GPMC in asynchronous single read mode.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 15.4.4.9.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
 - nCS assertion time is controlled by the [GPMC_CONFIG2_i\[3:0\] CSONTIME](#) field and ensures address setup time to nCS assertion.
 - nCS deassertion time is controlled by the [GPMC_CONFIG2_i\[12:8\] CSRDOFFTIME](#) field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\] ADVONTIME](#) field.
 - nADV deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\] ADVRDOFFTIME](#) field.
- Output enable signal nOE:
 - nOE assertion indicates a read cycle.
 - nOE assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\] OEONTIME](#) field.
 - nOE deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\] OEOFFTIME](#) field.
- Initial latency for the first read data is controlled by [GPMC_CONFIG5_i\[20:16\] RDACCESSTIME](#) or by monitoring the WAIT signal.
- Total access time ([GPMC_CONFIG5_i\[4:0\] RDCYCLETIME](#)) corresponds to RDACCESSTIME plus the address hold time from nCS deassertion, plus time from RDACCESSTIME to CSRDOFFTIME.
- Direction signal DIR: DIR goes from OUT to IN at the same time as nOE assertion.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled in the same way as for synchronous single read operation on an address/data-multiplexed device.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME field.
 - nOE first deassertion time is controlled by the [GPMC_CONFIG3_i\[15:13\]](#) OEAADMUXOFFTIME field.
 - nOE second assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field.
 - nOE second deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME field.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 15.4.4.10.10](#), *Bus Keeping Support*.

15.4.4.11.2.2 Synchronous Multiple (Burst) Read (4-, 8-, 16-Word16 Burst With Wraparound Capability)

[Figure 15-68](#) and [Figure 15-69](#) show a synchronous multiple read operation with GPMCFCLKDivider equal to 0 and 1, respectively.

Figure 15-68. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 0)

Figure 15-69. Synchronous Multiple (Burst) Read (GPMCFCLKDIVIDER = 1)

gpmc-019

When [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

The nCS, nADV, nOE and DIR signals are controlled in the same way as for synchronous single read operation. See [Table 15-244](#).

Initial latency for the first read data is controlled by RDACCESSTIME or by monitoring the WAIT signal. Successive read data are provided by the memory device each one or two GPMC_CLK cycles. The PAGEBURSTACCESSTIME parameter must be set accordingly with [GPMC_CONFIG1_i\[1:0\]](#) GPMCFCLKDIVIDER and the memory-device internal configuration. Depending on the device page length, the GPMC checks device page crossing during a new burst request and purposely insert initial latency (of RDACCESSTIME) when required.

Total access time [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time from nCS deassertion. In [Figure 15-69](#), RDCYCLETIME programmed value equals to RDCYCLETIME0 + RDCYCLETIME1.

After a read operation, if no other access (read or write) is pending, the data bus is driven with the previous read value. See [Section 15.4.4.10.10, Bus Keeping Support](#).

Burst wraparound is enabled through the [GPMC_CONFIG1_i\[31\]](#) WRAPBURST bit and allows a 4-, 8-, or 16-Word16 linear burst access to wrap within its burst-length boundary through [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH.

15.4.4.11.2.3 Synchronous Single Write

Burst write mode is used for synchronous single or burst accesses.

Figure 15-70. Synchronous Single Write on an Address/Data-Multiplexed Device

When the GPMC generates a write access to an address/data-multiplexed device, it drives the data bus (with address bits A[16:1]) until **GPMC_CONFIG6_i[19:16]** WRDATAONADMUXBUS time. First data of the burst is driven on the address/data bus at WRDATAONADMUXBUS time.

15.4.4.11.2.4 Synchronous Multiple (Burst) Write

Synchronous burst write mode provides synchronous single or consecutive accesses.

[Figure 15-71](#) shows a synchronous burst write access when the chip-select is configured in address/data-multiplexed mode.

Figure 15-71. Synchronous Multiple Write (Burst Write) in Address/Data-Multiplexed Mode

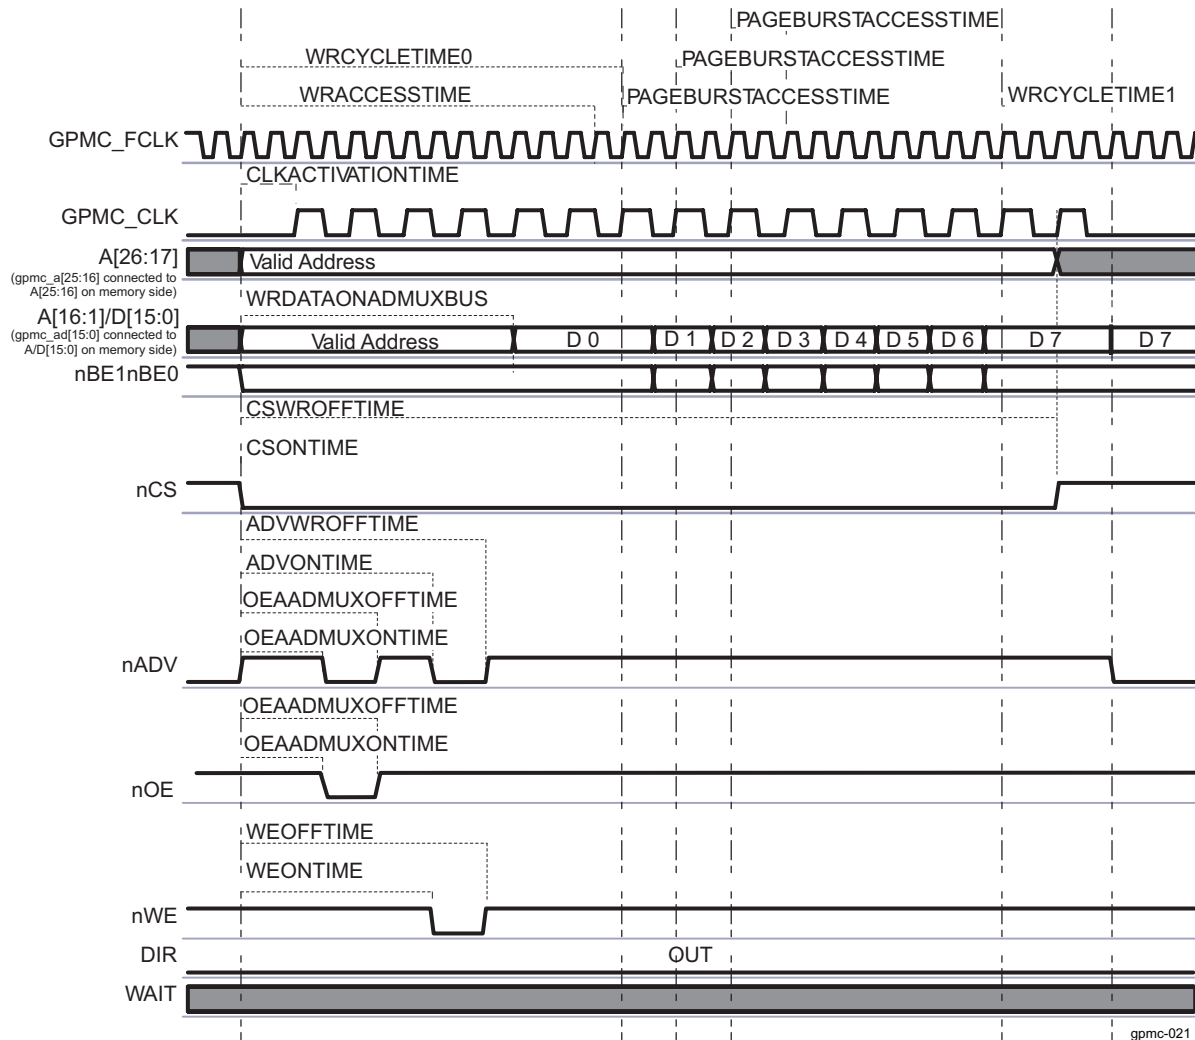

Figure 15-72 shows the same synchronous burst write access when the chip-select is configured in address/address/data-multiplexed (AAD-multiplexed) mode.

Figure 15-72. Synchronous Multiple Write (Burst Write) in Address/Address/Data-Multiplexed Mode

The first data of the burst is driven on the A/D bus at [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS.

When WRACCESTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to the [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESTIME multiplied by the number of remaining data transactions.

When the GPMC generates a read access to an address/data-multiplexed device, it drives the address bus until nOE assertion time. For details, see [Section 15.4.4.9.2.3, Address/Data-Multiplexing Interface](#).

- Chip-select signal nCS:
 - nCS assertion time is controlled by the [GPMC_CONFIG2_i\[3:0\]](#) CSONTIME field ($i = 0$ to 7) and ensures address setup time to nCS assertion.
 - nCS deassertion time controlled by the [GPMC_CONFIG2_i\[20:16\]](#) CSWROFFTIME field and ensures address hold time to nCS deassertion.
- Address valid signal nADV:
 - nADV assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV deassertion time is controlled by the [GPMC_CONFIG3_i\[20:16\]](#) ADVWROFFTIME field.
- Write enable signal nWE:
 - nWE assertion indicates a read cycle.
 - nWE assertion time is controlled by the [GPMC_CONFIG4_i\[19:16\]](#) WEONTIME field.

- nWE deassertion time is controlled by the [GPMC_CONFIG4_i\[28:24\]](#) WEOFFTIME field.

NOTE: The nWE falling edge must not be used to control the time when the burst first data is driven in the address/data bus because some new devices require the nWE signal at low during the address phase.

- Direction signal DIR is OUT during the entire access.

When the GPMC generates a write access to an AAD-multiplexed device, all address bits are driven onto the address/data bus in two separate phases. The first phase is used for the MSB address and is qualified with nOE driven low. The second phase for LSB address is qualified with nOE driven high. The address phase ends at nWE assertion time.

The nCS, and DIR signals are controlled as detailed above.

- Address valid signal nADV is asserted and deasserted twice during a read transaction:
 - nADV first assertion time is controlled by the [GPMC_CONFIG3_i\[6:4\]](#) ADVAADMUXONTIME field.
 - nADV first deassertion time is controlled by the [GPMC_CONFIG3_i\[26:24\]](#) ADVAADMUXRDOFFTIME field.
 - nADV second assertion time is controlled by the [GPMC_CONFIG3_i\[3:0\]](#) ADVONTIME field.
 - nADV second deassertion time is controlled by the [GPMC_CONFIG3_i\[12:8\]](#) ADVRDOFFTIME field.
- Output Enable signal nOE is asserted and deasserted twice during a read transaction (nOE second assertion indicates a read cycle):
 - nOE first assertion time is controlled by the [GPMC_CONFIG4_i\[6:4\]](#) OEAADMUXONTIME field.
 - nOE first deassertion time is controlled by the [GPMC_CONFIG4_i\[15:13\]](#) OEAADMUXOFFTIME field.
 - nOE second assertion time is controlled by the [GPMC_CONFIG4_i\[3:0\]](#) OEONTIME field.
 - nOE second deassertion time is controlled by the [GPMC_CONFIG4_i\[12:8\]](#) OEOFFTIME field.

First write data is driven by the GPMC at [GPMC_CONFIG6_i\[19:16\]](#) WRDATAONADMUXBUS, when in address/data mux configuration. The next write data of the burst is driven on the bus at WRACCESSTIME + 1 during [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME GPMC_FCLK cycles. The last data of the synchronous burst write is driven until [GPMC_CONFIG5_i\[12:8\]](#) WRCYCLETIME completes.

- WRACCESSTIME is defined in the [GPMC_CONFIG6_i\[28:24\]](#) register.
- The PAGEBURSTACCESSTIME parameter must be set accordingly with GPMCFCLKDIVIDER and the memory-device internal configuration.

Total access time [GPMC_CONFIG5_i\[12:8\]](#) WRCYCLETIME corresponds to WRACCESSTIME plus the address hold time from nCS deassertion. In [Figure 15-71](#), the WRCYCLETIME programmed value equals WRCYCLETIME0 + WRCYCLETIME1. WRCYCLETIME0 and WRCYCLETIME1 delays are not actual parameters and are only a graphical representation of the full WRCYCLETIME value.

After a write operation, if no other access (read or write) is pending, the data bus keeps the previous value. See [Section 15.4.4.10.10, Bus Keeping Support](#).

15.4.4.11.3 Asynchronous and Synchronous Accesses in Nonmultiplexed Mode

Page mode is only available in non-muxed mode. The non-muxed mode is described in this section even though its use is very limited (address space limited to 2 KBytes).

- Asynchronous single read operation on a nonmultiplexed device
- Asynchronous single write operation on a nonmultiplexed device
- Asynchronous multiple (page mode) read operation on a nonmultiplexed device
- Synchronous operations on a nonmultiplexed device

15.4.4.11.3.1 Asynchronous Single Read Operation on a Nonmultiplexed Device

[Figure 15-73](#) shows an asynchronous single read operation on a nonmultiplexed device.

Figure 15-73. Asynchronous Single Read on an Address/Data-Nonmultiplexed Device

The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Read data is latched at [GPMC_CONFIG1_5\[20:16\]](#) RDACCESSTIME completion time. The end of the access is defined by the [GPMC_CONFIG1_5\[4:0\]](#) RDCYCLETIME parameter.

Set [GPMC_CONFIG\[1\]](#) LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

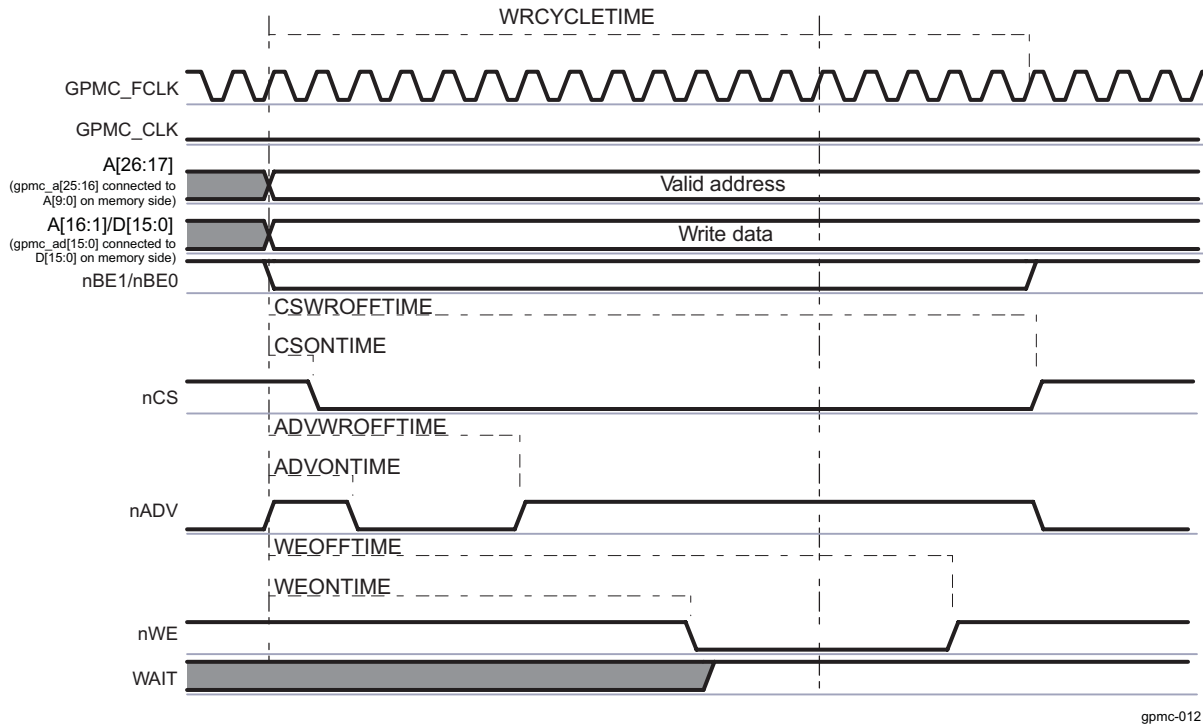

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-249](#).

gpmc-010

15.4.4.11.3.2 Asynchronous Single Write Operation on a Nonmultiplexed Device

[Figure 15-74](#) shows an asynchronous single write operation on a nonmultiplexed device.

Figure 15-74. Asynchronous Single Write on an Address/Data-Nonmultiplexed Device

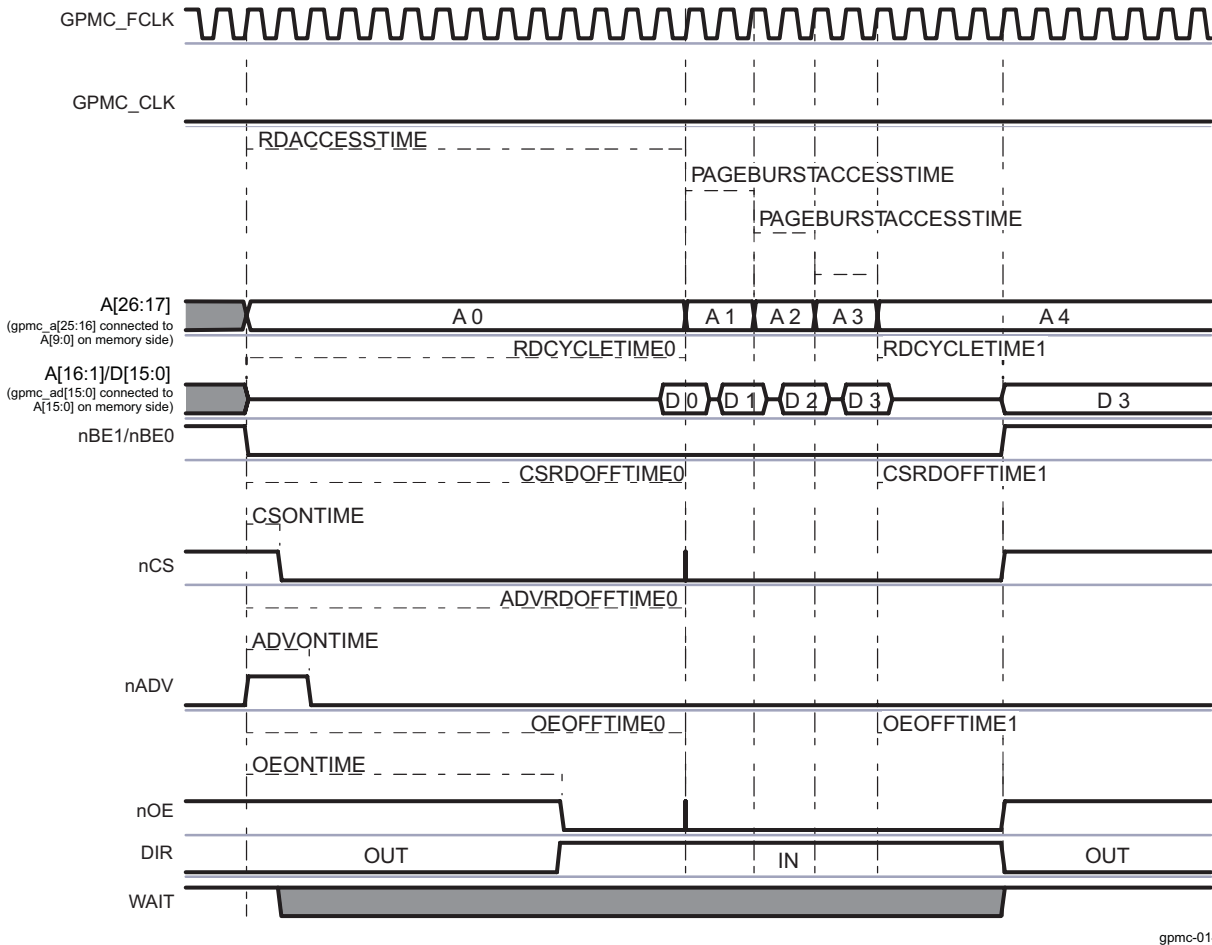

The 10-bit address is driven onto the address bus A[10:1] and the 16-bit data is driven onto the data bus D[15:0].

Set `GPMC_CONFIG[1] LIMITEDADDRESS` to 0x1 (A26-A11 are not modified during an external memory access).

nCS, nADV, nWE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-249](#).

15.4.4.11.3.3 Asynchronous Multiple (Page Mode) Read Operation on a Nonmultiplexed Device

[Figure 15-75](#) shows an asynchronous multiple read operation on a Nonmultiplexed Device, in which two word32 host read accesses to the GPMC are split into one multiple (page mode of 4 word16) read access to the attached device.

Figure 15-75. Asynchronous Multiple (Page Mode) Read

gpmc-014

NOTE: The WAIT signal is active low.

nCS, nADV, nOE and DIR signals are controlled in the same way as address/data multiplexed accesses, see [Table 15-249](#).

When RDACCESSTIME completes, control-signal timings are frozen during the multiple data transactions, corresponding to PAGEBURSTACCESSTIME multiplied by the number of remaining data transactions.

Read data is latched at [GPMC_CONFIG5_i\[20:16\]](#) RDACCESSTIME completion time ($i = 0$ to 7). The end of the access is defined by the [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME parameter.

Set [GPMC_CONFIG\[1\]](#) LIMITEDADDRESS to 0x1 (A26-A11 are not modified during an external memory access).

During consecutive accesses, the GPMC increments the address after each data read completes.

Delay between successive read data in the page is controlled by the [GPMC_CONFIG5_i\[27:24\]](#) PAGEBURSTACCESSTIME parameter. Depending on the device page length, the GPMC can control device page crossing during a burst request and insert initial RDACCESSTIME latency. Note that page crossing is only possible with a new burst access, meaning a new initial access phase is initiated.

Total access time RDCYCLETIME corresponds to RDACCESSTIME plus the address hold time starting from the nCS deassertion.

- The read cycle time is defined in the [GPMC_CONFIG5_i\[4:0\]](#) RDCYCLETIME field.
- In [Figure 15-75](#), the RDCYCLETIME programmed value equals RDCYCLETIME0 (before paged accesses) + RDCYCLETIME1 (after paged accesses).

15.4.4.11.3.4 Synchronous Operations on a Nonmultiplexed Device

All information for this section is equivalent to similar operations for address/data- or AAD-multiplexed accesses. The only difference resides in the address phase. See [Section 15.4.5.3, GPMC Configuration in NOR Mode](#).

15.4.4.11.4 Page and Burst Support

Each chip-select can be configured to process system single or burst requests into successive single accesses or asynchronous page/synchronous burst accesses, with appropriate access size adaptation.

Depending on the external device page or burst capability, read and write accesses can be independently configured through the GPMC. The [GPMC_CONFIG1_i\[30\]](#) READMULTIPLE and [GPMC_CONFIG1_i\[28\]](#) WRITMULTIPLE bits ($i = 0$ to 7) are associated with the READTYPE and WRITETYPE parameters.

NOTE:

- Asynchronous write page mode is not supported.
 - 8-bit wide device support is limited to nonburstable devices (READMULTIPLE and WRITEMULTIPLE are ignored).
 - Not applicable to NAND device interfacing.
-

15.4.4.11.5 System Burst Versus External Device Burst Support

The device system can issue the following requests to the GPMC:

- Byte, 16-bit word, 32-bit word requests (byte enable controlled). This is always a single request from the interconnect point of view.
- Incrementing fixed-length bursts of two words, four words, and eight words
- Wrapped (critical word access first) fixed-length burst of two, four, or eight words

To process a system request with the optimal protocol, the READMULTIPLE (and READTYPE) and WRITEMULTIPLE (and WRITETYPE) parameters must be set according to the burstable capability (synchronous or asynchronous) of the attached device.

The GPMC access engine issues only fixed-length burst. The maximum length that can be issued is defined per CS by the [GPMC_CONFIG1_i\[24:23\]](#) ATTACHEDDEVICEPAGELENGTH field ($i = 0$ to 7). When the ATTACHEDDEVICEPAGELENGTH value is less than the system burst request length (including the appropriate access size adaptation according to the device width), the GPMC splits the system burst request into multiple bursts. Within the specified 4-, 8-, or 16-word value, the ATTACHEDDEVICEPAGELENGTH field value must correspond to the maximum-length burst supported by the memory device configured in fixed-length burst mode (as opposed to continuous burst mode).

To get optimal performance from memory devices that natively support 16 Word16-length-wrapping burst capability (critical word access first), the ATTACHEDDEVICEPAGELENGTH parameter must be set to 16 words and the [GPMC_CONFIG1_i\[31\]](#) WRAPBURST bit ($i = 0$ to 7) must be set to 1. Similarly DEVICESPAGELENGTH is set to 4 and 8 for memories supporting respectively 4 and 8 Word16-length-wrapping burst.

When the memory device does not offer (or is not configured to offer) native 16 Word16-length-wrapping burst, the WRAPBURST parameter must be cleared, and the GPMC access engine emulates the wrapping burst by issuing the appropriate burst sequences according to the ATTACHEDDEVICEPAGELENGTH value.

When the memory device does not support native-wrapping burst, there is usually no difference in behavior between a fixed burst length mode and a continuous burst mode configuration (except for a potential power increase from a memory-speculative data prefetch in a continuous burst read). However, even though continuous burst mode is compatible with GPMC behavior, because the GPMC access engine issues only fixed-length burst and does not benefit from continuous burst mode, it is best to configure the memory device in fixed-length burst mode.

The memory device maximum-length burst (configured in fixed-length burst wrap or nonwrap mode) usually corresponds to the memory device data buffer size. Memory devices with a minimum of 16 half-word buffers are the most appropriate (especially with wrap support), but memory devices with smaller buffer size (4 or 8) are also supported, assuming that the `GPMC_CONFIG1_i[24:23]` `ATTACHEDDEVICEPAGELENGTH` field is set accordingly to 4 or 8 words.

The device system issues only requests with addresses or starting addresses for nonwrapping burst requests; that is, the request size boundary is aligned. In case of an eight-word-wrapping burst, the wrapping address always occurs on the eight-words boundary. As a consequence, all words requested must be available from the memory data buffer when the buffer size is equal to or greater than the `ATTACHEDDEVICEPAGELENGTH` value. This usually means that data can be read from or written to the buffer at a constant rate (number of cycles between data) without wait states between data accesses. If the memory does not behave this way (nonzero wait state burstable memory), wait-pin monitoring must be enabled to dynamically control data-access completion within the burst.

NOTE: When the system burst request length is less than the `ATTACHEDDEVICEPAGELENGTH` value, the GPMC proceeds with the required accesses.

15.4.4.12 pSRAM Access Specificities

pSRAM devices are SRAM-pin-compatible low-power memories that contain a self-refreshed DRAM memory array. The `GPMC_CONFIG1_i[11:10]` `DEVICETYPE` field ($i = 0$ to 7) must be set to 0b00.

The pSRAM devices uses the NOR protocol. It support the following operations:

- Asynchronous single read
- Asynchronous page read
- Asynchronous single write
- Synchronous single read and write
- Synchronous burst read
- Synchronous burst write (not supported by NOR Flash memory)

pSRAM devices must be powered up and initialized in a predefined manner according to the specifications of the attached device.

pSRAM devices can be programmed to use either mode: fixed or variable latency. pSRAM devices can either automatically schedule autorefresh operations, which force the GPMC to use its `WAIT` signal capability when read or write operations occur during an internal self-refresh operation, or pSRAM devices automatically include the autorefresh operation in the access time. These devices do not require additional `WAIT` signal capability or a minimum `nCS` high pulse width between consecutive accesses to ensure that the correct internal refresh operation is scheduled.

15.4.4.13 NAND Access Description

NAND (8-bit and 16-bit) memory devices using a standard NAND asynchronous address/data-multiplexing scheme can be supported on any chip-select with the appropriate asynchronous configuration settings.

As for any other type of memory compatible with the GPMC interface, accesses to a chip-select allocated to a NAND device can be interleaved with accesses to chip-selects allocated to other external devices. This interleaved capability limits the system to *chip enable don't care* NAND devices since the chip-select allocated to the NAND device has to be deasserted if accesses to other chip-selects are requested.

15.4.4.13.1 NAND Memory Device in Byte or 16-bit Word Stream Mode

NAND devices require correct command and address programming before data array read or write accesses. The GPMC does not include specific hardware to translate a random address system request into a NAND-specific multiphase access. In that sense, GPMC NAND support, as opposed to random memory-map device support, is data-stream-oriented (byte or 16-bit word).

The GPMC NAND programming model relies on a software driver for address and command formatting with the correct data address pointer value according to the block and page structure. Because of NAND structure and protocol interface diversity, the GPMC does not support automatic command and address phase programming, and software drivers must access the NAND device ID to ensure that correct command and address formatting are used for the identified device.

NAND device data read and write accesses are achieved through an asynchronous read or write access. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Any chip-select region can be qualified as a NAND region to constrain the nADV/ALE signal as Address Latch Enable (ALE active high, default state value at low) during address program access, and the nBE0/CLE signal as Command Latch Enable (CLE active high, default state value at low) during command program access. GPMC address lines are not used (the previous value is not changed) during NAND access.

15.4.4.13.1.1 Chip-Select Configuration for NAND Interfacing in Byte or Word Stream Mode

The [GPMC_CONFIG7_i](#) register (where $i = 0$ to 7) associated with a NAND device region interfaced in byte or word stream mode can be initialized with a minimum size of 16 Mbytes, because any address location in the chip-select memory region can be used to access a NAND data array. The NAND Flash protocol specifies an address sequence where address bits are passed through the data bus in a series of write accesses with the ALE pin asserted. After this address phase, all operations are streamed and the system requests address is irrelevant.

CAUTION

To allow correct command, address, and data-access controls, the [GPMC_CONFIG1_i](#) register associated with a NAND device region must be initialized in asynchronous read and write modes with the parameters shown in [Table 15-227](#). Failure to comply with these settings corrupts the NAND interface protocol.

Table 15-227. Chip-Select Configuration for NAND Interfacing

| Bit Field | Register | Value | Comments |
|--------------------------|----------------------------------------------------|--------------|--------------------------------------------------|
| WRAPBURST | GPMC_CONFIG1_i [31] ⁽¹⁾ | 0 | No wrap |
| READMULTIPLE | GPMC_CONFIG1_i [30] | 0 | Single access |
| READTYPE | GPMC_CONFIG1_i [29] | 0 | Asynchronous mode |
| WRITEMULTIPLE | GPMC_CONFIG1_i [28] | 0 | Single access |
| WRITETYPE | GPMC_CONFIG1_i [27] | 0 | Asynchronous mode |
| CLKACTIVATIONTIME | GPMC_CONFIG1_i [26:25] | 0b00 | |
| ATTACHEDDEVICEPAGELENGTH | GPMC_CONFIG1_i [24:23] | Don't care | Single-access mode |
| WAITREADMONITORING | GPMC_CONFIG1_i [22] | 0 | Wait not monitored by GPMC access engine |
| WAITWRITEMONITORING | GPMC_CONFIG1_i [21] | 0 | Wait not monitored by GPMC access engine |
| WAITMONITORINGTIME | GPMC_CONFIG1_i [19:18] | Don't care | Wait not monitored by GPMC access engine |
| WAITPINSELECT | GPMC_CONFIG1_i [17:16] | | Select which wait is monitored by edge detectors |
| DEVICESIZE | GPMC_CONFIG1_i [13:12] | 0b00 or 0b01 | 8- or 16-bit interface |
| DEVICETYPE | GPMC_CONFIG1_i [11:10] | 0b10 | NAND device in stream mode |
| MUXADDDATA | GPMC_CONFIG1_i [9:8] | 0b00 | Nonmultiplexed mode |

⁽¹⁾ $i = 0$ to 7

Table 15-227. Chip-Select Configuration for NAND Interfacing (continued)

| Bit Field | Register | Value | Comments |
|---------------------|-------------------------------------|------------|--------------------------------------------------|
| TIMEPARAGRANULARITY | GPMC_CONFIG1_i[4] | 0 | Timing achieved with best GPMC clock granularity |
| GPMCFCLKDIVIDER | GPMC_CONFIG1_i[1:0] | Don't care | Asynchronous mode |

The [GPMC_CONFIG1_i](#) to [GPMC_CONFIG4_i](#) register (where $i = 0$ to 7) associated with a NAND device region must be initialized with the correct control-signal timing value according to the NAND device timing parameters.

15.4.4.13.1.2 NAND Device Command and Address Phase Control

NAND devices require multiple address programming phases. The MPU software driver is responsible for issuing the correct number of command and address program accesses, according to the device command set and the device address-mapping scheme.

NAND device-command and address-phase programming is achieved through write requests to the [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) register locations ($i = 0$ to 7) with the correct command and address values. These locations are mapped in the associated chip-select register region. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Command and address values are not latched during the access and cannot be read back at the register location.

- Only write accesses must be issued to these locations, but the GPMC does not discard any read access. Accessing a NAND device with nOE and CLE or ALE asserted (read access) can produce undefined results.
- Write accesses to the [GPMC_NAND_COMMAND_i](#) register location and to the [GPMC_NAND_ADDRESS_i](#) register location must be posted for faster operations ($i = 0$ to 7). The [GPMC_CONFIG\[0\]](#) NANDFORCEPOSTEDWRITE bit enables write accesses to these locations as posted, even if they are defined as nonposted.

A write buffer is used to store write transaction information before the external device is accessed:

- Up to eight consecutive posted write accesses can be accepted and stored in the write buffer.
- For nonposted write, the pipeline is one deep.
- An [GPMC_STATUS\[0\]](#) EMPTYWRITEBUFFERSTATUS bit stores the empty status of the write buffer.

[GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) ($i = 0$ to 7) are 32-bit word locations, which means any 32-bit word or 16-bit word access is split into 4- or 2-byte accesses if an 8-bit wide NAND device is attached. For multiple-command phase or multiple-address phase, the software driver can use 32-bit word or 16-bit word access to these registers, but it must account for the splitting and little-endian ordering scheme. When only one byte command or address phase is required, only byte write access to [GPMC_NAND_COMMAND_i](#) and [GPMC_NAND_ADDRESS_i](#) can be used, and any of the four byte locations of the registers are valid.

The same applies to a [GPMC_NAND_COMMAND_i](#) and a [GPMC_NAND_ADDRESS_i](#) ($i = 0$ to 7) 32-bit word write access to a 16-bit wide NAND device (split into two 16-bit word accesses). In the case of a 16-bit word write access, the MSByte of the 16-bit word value must be set according to the NAND device requirement (usually 0). Either 16-bit word location or any one of the four byte locations of the registers is valid.

15.4.4.13.1.3 Command Latch Cycle

Writing data at the [GPMC_NAND_COMMAND_i](#) location ($i = 0$ to 7) places the data as the NAND command value on the bus, using a regular asynchronous write access.

- nCE is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- CLE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.

- ALE and nRE (nOE) are maintained inactive.

Figure 15-76 shows the NAND command latch cycle.

Figure 15-76. NAND Command Latch Cycle

gpmc-022

NOTE: CLE is shared with the nBE0 output signal and has an inverted polarity from BE0. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, nBE0 (also nBE1) must not toggle, because it is shared with CLE.

NAND Flash memories do not use byte enable signals at all.

15.4.4.13.1.4 Address Latch Cycle

Writing data at the [GPMC_NAND_ADDRESS_i](#) location (i = 0 to 7) places the data as the NAND partial address value on the bus, using a regular asynchronous write access.

- nCS is controlled by the CSONTIME and CSWROFFTIME timing parameters.
- ALE is controlled by the ADVONTIME and ADVWROFFTIME timing parameters.
- nWE is controlled by the WEONTIME and WEOFFTIME timing parameters.
- CLE and nRE (nOE) are maintained inactive.

Figure 15-77 shows the NAND address latch cycle.

Figure 15-77. NAND Address Latch Cycle

NOTE: ALE is shared with the nADV output signal and has an inverted polarity from ADV. The NAND qualifier deals with this. During the asynchronous NAND data access cycle, ALE is kept stable.

15.4.4.13.1.5 NAND Device Data Read and Write Phase Control in Stream Mode

NAND device data read and write accesses are achieved through a read or write request to the chip-select-associated memory region at any address location in the region or through a read or write request to the [GPMC_NAND_DATA_i](#) location ($i = 0$ to 7) mapped in the chip-select-associated control register region. [GPMC_NAND_DATA_i](#) is not a true register, but an address location to enable nRE or nWE signal control. The associated chip-select signal timing control must be programmed according to the NAND device timing specification.

Reading data from the [GPMC_NAND_DATA_i](#) location or from any location in the associated chip-select memory region activates an asynchronous read access.

- nCS is controlled by the CSONTIME and CSRDOFFTIME timing parameters.
- nRE is controlled by the OEONTIME and OEOFFTIME timing parameters.
- To take advantage of nRE high-to-data invalid minimum timing value, the RDACCESSTIME can be set so that data are effectively captured after nRE deassertion. This allows optimization of NAND read access cycle time completion. For optimal timing parameter settings, see the NAND device and the device IC timing parameters.

ALE, CLE, and nWE are maintained inactive.

[Figure 15-78](#) shows the NAND data read cycle.

Figure 15-78. NAND Data Read Cycle

Writing data to the [GPMC_NAND_DATA_i](#) location or to any location in the associated chip-select memory region activates an asynchronous write access.

- nCS is controlled by the CS ONTIME and CSWROFFTIME timing parameters.
- nWE is controlled by the WE ONTIME and WEOFFTIME timing parameters.
- ALE, CLE, and nRE (nOE) are maintained inactive.

Figure 15-79 shows the NAND data write cycle.

Figure 15-79. NAND Data Write Cycle

15.4.4.13.1.6 NAND Device General Chip-Select Timing Control Requirement

For most NAND devices, read data access time is dominated by nCS-to-data-valid timing and has faster nRE-to-data-valid timing. Successive accesses with nCS deassertions between accesses are affected by this timing constraint. Because accesses to a NAND device can be interleaved with other chip-select accesses, there is no certainty that nCS always stays low between two accesses to the same chip-select. Moreover, an nCS deassertion time between the same chip-select NAND accesses is likely to be required as follows: the nCS deassertion requires programming CYCLETIME and RDACCESSTIME according to the nCS-to-data-valid critical timing.

To get full performance from NAND read and write accesses, the prefetch engine can dynamically reduce RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSRDOFFTIME, CSWROFFTIME, ADVRDOFFTIME, ADVWROFFTIME, OEOFFTIME, and WEOFFTIME on back-to-back NAND accesses (to the same memory) and suppress the minimum nCS high pulse width between accesses. For more information about optimal prefetch engine access, see [Section 15.4.4.13.4](#), *Prefetch and Write-Posting Engine*.

Some NAND devices require minimum write-to-read idle time, especially for device-status read accesses following status-read command programming (write access). If such write-to-read transactions are used, a minimum nCS high pulse width must be set. For this, CYCLE2CYCLESAMEECSEN and CYCLE2CYCLEDELAY must be set according to the appropriate timing requirement to prevent any timing violation.

NAND devices usually have an important nRE high to data bus in tristate mode. This requires a bus turnaround setting (BUSTURNAROUND = 1), so that the next access to a different chip-select is delayed until the BUSTURNAROUND delay completes. Back-to-back NAND read accesses to the same NAND Flash are not affected by the programmed bus turnaround delay.

15.4.4.13.1.7 Read and Write Access Size Adaptation

15.4.4.13.1.7.1 8-bit wide NAND Device

Host 16-bit word and 32-bit word read and write access requests to a chip-select associated with an 8-bit wide NAND device are split into successive read and write byte accesses to the NAND memory device. Byte access is ordered according to little-endian organization. A NAND 8-bit wide device must be interfaced on the D0D7 interface bus lane. GPMC data accesses are justified on this bus lane when the chip-select is associated with an 8-bit wide NAND device.

15.4.4.13.1.7.2 16-bit wide NAND Device

Host 32-bit word read and write access requests to a chip-select associated with a 16-bit wide NAND device are split into successive read and write 16-bit word accesses to the NAND memory device. 16-bit word access is ordered according to little-endian organization.

Host byte read and write access requests to a 16-bit wide NAND device are completed as 16-bit accesses on the device itself, because there is no byte-addressing capability on 16-bit wide NAND devices. This means that the NAND device address pointer is incremented on a 16-bit word basis and not on a byte basis. For a read access, only the requested byte is given back to the host, but the remaining byte is not stored or saved by the GPMC, and the next byte or 16-bit word read access gets the next 16-bit word NAND location. For a write access, the invalid byte part of the 16-bit word is driven to FF, and the next byte or 16-bit word write access programs the next 16-bit word NAND location.

Generally, byte access to a 16-bit wide NAND device should be avoided, especially when ECC calculation is enabled. 8-bit or 16-bit ECC-based computations are corrupted by a byte read to a 16-bit wide NAND device, because the nonrequested byte is considered invalid on a read access (not captured on the external data bus; FF is fed to the ECC engine) and is set to FF on a write access.

Host requests (read/write) issued in the chip-select memory region are translated in successive single or split accesses (read/write) to the attached device. Therefore, incrementing 32-bit burst requests are translated in multiple 32-bit sequential accesses following the access adaptation of the 32-bit to 8- or 16-bit device.

15.4.4.13.2 NAND Device-Ready Pin

The NAND memory device provides a ready pin to indicate data availability after a block/page opening and to indicate that data programming is complete. The ready pin can be connected to one of the WAIT GPMC input pins; data read accesses must not be tried when the ready pin is sampled inactive (device is not ready) even if the associated chip-select WAITREADMONITORING bit field is set. The duration of the NAND device busy state after the block/page opening is so long (up to 50 micro second) that accesses occurring when the ready pin is sampled inactive can stall GPMC access and eventually cause a system time-out.

NOTE: If a read access to a NAND flash is done using the wait monitoring mode, the device is blocked during a page opening, and so is the GPMC. If the correct settings are used, other chip-selects can be used while the memory processes the page opening command.

To avoid a time-out caused by a block/page opening delay in NAND flash, disable the wait pin monitoring for read and write accesses (that is, set the [GPMC_CONFIG1_i\[21\]](#) WAITWRITEMONITORING and [GPMC_CONFIG1_i\[22\]](#) WAITREADMONITORING bits to 0, where $i = 0$ to 7), and use one of the following methods instead:

- Use software to poll the WAITnSTATUS bit ($n = 0$ to 3) of the [GPMC_STATUS](#) register.
- Configure an interrupt that is generated on the WAIT signal change (through the [GPMC_IRQENABLE](#) register bits[11:8]).

Even if the READWAITMONITORING bit is not set, the external memory nR/B pin status is captured in the programmed WAIT bit in the [GPMC_STATUS](#) register.

The READWAITMONITORING bit method must be used for other memories than NAND flash, if they require the use of a WAIT signal.

15.4.4.13.2.1 Ready Pin Monitored by Software Polling

The ready signal state can be monitored through the [GPMC_STATUS](#) WAITxSTATUS bit ($x = 0$ or 1). The software must monitor the ready pin only when the signal is declared valid. Refer to the NAND device timing parameters to set the correct software temporization to monitor ready only after the invalid window is complete from the last read command written to the NAND device.

15.4.4.13.2.2 Ready Pin Monitored by Hardware Interrupt

Each gpmc_wait input pin can generate an interrupt when a wait-to-no-wait transition is detected. Depending on whether the [GPMC_CONFIG](#) WAITxPINPOLARITY bits ($x = 0$ or 1) is active low or active high, the wait-to-no-wait transition is a low-to-high external WAIT signal transition or a high-to-low external WAIT signal transition, respectively.

The wait transition pin detector must be cleared before any transition detection. This is done by writing 1 to the WAITxEDGEDETECTIONSTATUS bit ($x = 0$ or 3) of the [GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for the NAND device-ready signal monitoring. To detect a wait-to-no-wait transition, the transition detector requires a wait active time detection of a minimum of two GPMC_FCLK cycles. Software must incorporate precautions to clear the wait transition pin detector before wait (busy) time completes.

A wait-to-no-wait transition detection can issue a GPMC interrupt if the WAITxEDGEDETECTIONENABLE bit in the [GPMC_IRQENABLE](#) register is set and if the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC_IRQSTATUS](#) register is set.

The WAITMONITORINGTIME field does not affect wait-to-no-wait transition time detection.

It is also possible to poll the WAITxEDGEDETECTIONSTATUS bit field in the [GPMC_IRQSTATUS](#) register according to the gpmc_wait pin used for the NAND device ready signal monitoring.

15.4.4.13.3 ECC Calculator

The General Purpose Memory Controller includes an Error Code Correction (ECC) calculator circuitry that enables on the fly ECC calculation during data read or data program (that is, write) operations. The page size supported by the ECC calculator in one calculation/context is 512 bytes.

The user can choose from two different algorithms with different error correction capabilities through the [GPMC_ECC_CONFIG\[16\]](#) ECCALGORITHM bit:

1. Hamming code for 1-bit error code correction on 8- or 16-bit NAND Flash organized with page size greater than 512 bytes
2. BCH (Bose-Chaudhuri-Hocquenghem) code for 4- to 16-bit error correction

The GPMC does not directly handle the error code correction itself. During writes, the GPMC computes parity bits. During reads, the GPMC provides enough information for the processor to correct errors without reading the data buffer all over again.

The Hamming code ECC is based on a 2-dimensional (row and column) bit parity accumulation. This parity accumulation is either accomplished on the programmed number of bytes or 16-bit words read from the memory device, or written to the memory device in stream mode.

Because the ECC engine includes only one accumulation context, it can be allocated to only one chip-select at a time through the `GPMC_ECC_CONFIG[3:1]` ECCCS bit field. Even if two CS use different ECC algorithms, one the Hamming code and the other a BCH code, they must define separate ECC contexts because some of the ECC registers are common to all types of algorithms.

15.4.4.13.3.1 Hamming Code

All references to Error Code Correction (ECC) in this subsection refer to the 1-bit error correction Hamming code.

The ECC is based on a two-dimensional (row and column) bit parity accumulation known as Hamming Code. The parity accumulation is done for a programmed number of bytes or 16-bit word read from the memory device or written to the memory device in stream mode.

There is no automatic error detection or correction, and it is the software NAND driver responsibility to read the multiple ECC calculation results, compare them to the expected code value, and take the appropriate corrective actions according to the error handling strategy (ECC storage in spare byte, error correction on read, block invalidation).

The ECC engine includes a single accumulation context. It can be allocated to a single designated chip-select at a time and parallel computations on different chip-selects are not possible. Since it is allocated to a single chip-select, the ECC computation is not affected by interleaved GPMC accesses to other chip-selects and devices. The ECC accumulation is sequentially processed in the order of data read from or written to the memory on the designated chip-select. The ECC engine does not differentiate read accesses from write accesses and does not differentiate data from command or status information. It is the software responsibility to make sure only relevant data are passed to the NAND flash memory while the ECC computation engine is active.

The starting NAND page location must be programmed first, followed by an ECC accumulation context reset with an ECC enabling, if required. The NAND device accesses discussed in the following sections must be limited to data read or write until the specified number of ECC calculations is completed.

15.4.4.13.3.1.1 ECC Result Register and ECC Computation Accumulation Size

The GPMC includes up to nine ECC result registers (`GPMC_ECCj_RESULT`, $j = 1$ to 9) to store ECC computation results when the specified number of bytes or 16-bit words has been computed.

The ECC result registers are used sequentially; one ECC result is stored in one ECC result register on the list, the next ECC result is stored in the next ECC result register on the list, and so forth, until the last ECC computation. The `GPMC_ECCj_RESULT` register value is valid only when the programmed number of bytes or 16-bit words has been accumulated, which means that the same number of bytes or 16-bit words has been read from or written to the NAND device in sequence.

The `GPMC_ECC_CONTROL[3:0]` ECCPOINTER field must be set to the correct value to select the ECC result register to be used first in the list for the incoming ECC computation process. The ECCPointer can be read to determine which ECC register is used in the next ECC result storage for the ongoing ECC computation. The `GPMC_ECCj_RESULT` register value ($j = 1$ to 9) can be considered valid when ECCPOINTER equals $j + 1$. When `GPMC_ECCj_RESULT` (where $j = 9$) is updated, ECCPOINTER is frozen at 10, and ECC computing is stopped (ECCENABLE = 0).

The ECC accumulator must be reset before any ECC computation accumulation process. The `GPMC_ECC_CONTROL[8]` ECCCLEAR bit must be set to 1 (nonpersistent bit) to clear the accumulator and all ECC result registers.

For each ECC result (each `GPMC_ECCj_RESULT` register, $j = 1$ to 9), the number of bytes or 16-bit words used for ECC computing accumulation can be selected from between two programmable values.

The ECCjRESULTSISE bits (j = 1 to 9) in the [GPMC_ECC_SIZE_CONFIG](#) register select which programmable size value (ECCSIZE0 or ECCSIZE1) must be used for this ECC result (stored in [GPMC_ECCj_RESULT](#)).

The ECCSIZE0 and ECCSIZE1 fields allow selection of the number of bytes or 16-bit words used for ECC computation accumulation. Any even values from 2 to 512 are allowed.

Flexibility in the number of ECCs computed and the number of bytes or 16-bit words used in the successive ECC computations enables different NAND page error-correction strategies. Usually based on 256 or 512 bytes and on 128 or 256 16-bit word, the number of ECC results required is a function of the NAND device page size. Specific ECC accumulation size can be used when computing the ECC on the NAND spare byte.

For example, with a 2 Kbyte data page 8-bit wide NAND device, eight ECCs accumulated on 256 bytes can be computed and added to one extra ECC computed on the 24 spare bytes area where the eight ECC results used for comparison and correction with the computed data page ECC are stored. The GPMC then provides nine [GPMC_ECCj_RESULT](#) registers (j= 1 to 9) to store the results. In this case, ECCSIZE0 is set to 256, and ECCSIZE1 is set to 24; the ECC[1:8]RESULTSISE bits are set to 0, and the ECC9RESULTSISE bit is set to 1.

15.4.4.13.3.1.2 ECC Enabling

The [GPMC_ECC_CONFIG](#)[3:1] ECCCS field selects the allocated chip-select. The [GPMC_ECC_CONFIG](#)[0] ECCENABLE bit enables ECC computation on the next detected read or write access to the selected chip-select.

The ECCPOINTER, ECCCLEAR, ECCSIZE, ECCjRESULTSISE (where j = 1 to 9), ECC16B, and ECCCS fields must not be changed or cleared while an ECC computation is in progress.

The ECC accumulator and ECC result register must not be changed or cleared while an ECC computation is in progress.

[Table 15-228](#) describes the ECC enable settings.

Table 15-228. ECC Enable Settings

| Bit Field | Register | Value | Comments |
|-----------------------------------|--------------------------------------|-----------|---------------------------------------------------------------------------------------------------------------------------|
| ECCCS | GPMC_ECC_CONFIG | 0-3 | Selects the chip-select where ECC is computed |
| ECC16B | GPMC_ECC_CONFIG | 0/1 | Selects column number for ECC calculation |
| ECCCLEAR | GPMC_ECC_CONTROL | 0-7 | Clears all ECC result registers |
| ECCPOINTER | GPMC_ECC_CONTROL | 0-7 | A write to this bit field selects the ECC result register where the first ECC computation is stored. Set to 1 by default. |
| ECCSIZE1 | GPMC_ECC_SIZE_CONFIG | 0x00-0xFF | Defines ECCSIZE1 |
| ECCSIZE0 | GPMC_ECC_SIZE_CONFIG | 0x00-0xFF | Defines ECCSIZE0 |
| ECCjRESULTSISE (j from 1 to 9) | GPMC_ECC_SIZE_CONFIG | 0/1 | Selects the size of ECCn result register |
| ECCENABLE | GPMC_ECC_CONFIG | 1 | Enables the ECC computation |

15.4.4.13.3.1.3 ECC Computation

The ECC algorithm is a multiple parity bit accumulation computed on the odd and even bit streams extracted from the byte or Word 16 streams. The parity accumulation is split into row and column accumulations, as shown in [Figure 15-80](#) and [Figure 15-81](#). The intermediate row and column parities are used to compute the upper level row and column parities. Only the final computation of each parity bit is used for ECC comparison and correction.

P1o = bit7 XOR bit5 XOR bit3 XOR bit1 on each byte of the data stream

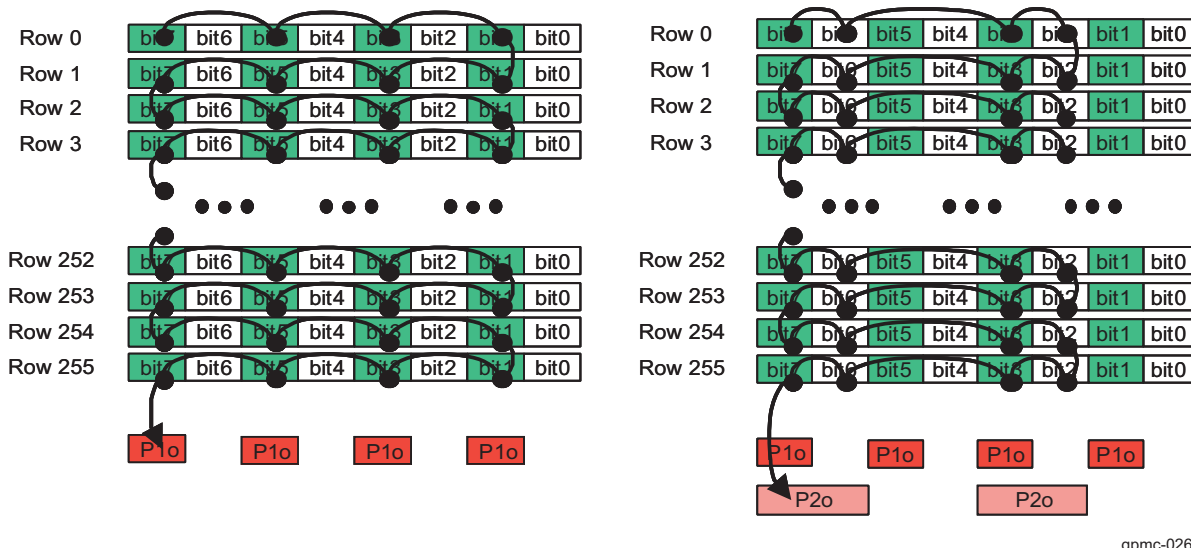

P1e = bit6 XOR bit4 XOR bit2 XOR bit0 on each byte of the data stream

P2o = bit7 XOR bit6 XOR bit3 XOR bit2 on each byte of the data stream

P2e = bit5 XOR bit4 XOR bit1 XOR bit0 on each byte of the data stream

P4o = bit7 XOR bit6 XOR bit5 XOR bit4 on each byte of the data stream
 P4e = bit3 XOR bit2 XOR bit1 XOR bit0 on each byte of the data stream
 Each column parity bit is XORed with the previous accumulated value.

Figure 15-80. Hamming Code Accumulation Algorithm (1/2)

gpmc-026

For line parities, the bits of each new data are XORed together, and line parity bits are computed as described below:

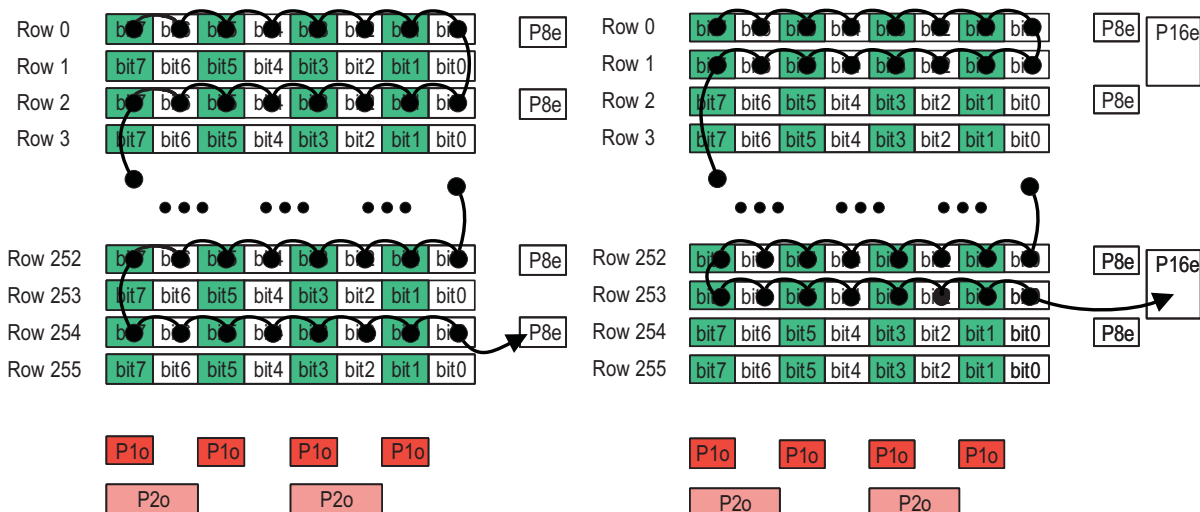

$$P8e = \text{row0 XOR row2 XOR row4 XOR ... XOR row254}$$

$$P8o = \text{row1 XOR row3 XOR row5 XOR ... XOR row255}$$

$$P16e = \text{row0 XOR row1 XOR row4 XOR row5 XOR ... XOR row252 XOR row 253}$$

$$P16o = \text{row2 XOR row3 XOR row6 XOR row7 XOR ... XOR row254 XOR row 255}$$

Figure 15-81. Hamming Code Accumulation Algorithm (2/2)

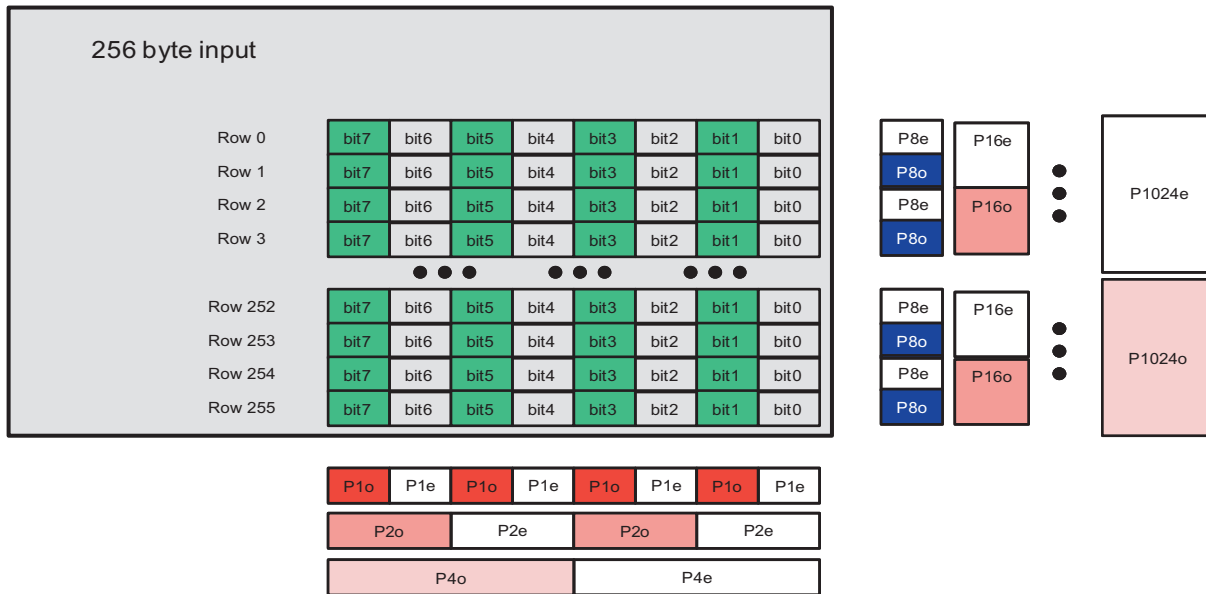

gpmc-027

Unused parity bits in the result registers are set to 0.

Figure 15-82 shows ECC computation for a 256-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and sixteen row parity bits (P8o-P16o-P32o--P1024o for odd parities, and P8e-P16e-P32e--P1024e for even parities).

Figure 15-82. ECC Computation for a 256-Byte Data Stream (Read or Write)

gpmc-028

Figure 15-83 shows ECC computation for a 512-byte data stream (read or write). The result includes six column parity bits (P1o-P2o-P4o for odd parities, and P1e-P2e-P4e for even parities) and eighteen row parity bits (P8o-P16o-P32o--P1024o- - P2048o for odd parities, and P8e-P16e-P32e--P1024e- P2048e for even parities).

Figure 15-83. ECC Computation for a 512-Byte Data Stream (Read or Write)

gpmc-029

For a 2 Kbytes page, four 512 bytes ECC calculations plus one for the spare area are required. Results are stored in the [GPMC_ECCj_RESULT](#) registers (j = 1 to 9).

15.4.4.13.3.1.4 ECC Comparison and Correction

To detect an error, the computed ECC result must be XORed with the parity value stored in the spare area of the accessed page.

- If the result of this logical XOR is all 0s, no error is detected and the read data is correct.
- If every second bit in the parity result is a 1, one bit is corrupted and is located at bit address (P2048o, P1024o, P512o, P256o, P128o, P64o, P32o, P16o, P8o, P4o, P2o, P1o). The software must correct the corresponding bit.
- If only one bit in the parity result is 1, it is an ECC error and the read data is correct.

15.4.4.13.3.1.5 ECC Calculation Based on 8-Bit Word

The 8-bit based ECC computation is used for 8-bit wide NAND device interfacing.

The 8-bit based ECC computation can be used for 16-bit wide NAND device interfacing to get backward compatibility on the error-handling strategy used with 8-bit wide NAND devices. In this case, the 16-bit wide data read from or written to the NAND device is fragmented into 2 bytes. According to little-endian access, the least significant bit (LSB) of the 16-bit wide data is ordered first in the byte stream used for 8-bit based ECC computation.

15.4.4.13.3.1.6 ECC Calculation Based on 16-Bit Word

ECC computation based on a 16-bit word is used for 16-bit wide NAND device interfacing. This ECC computation is not supported when interfacing an 8-bit wide NAND device, and the [GPMC_ECC_CONFIG\[7\]](#) ECC16B bit must be set to 0 when interfacing an 8-bit wide NAND device.

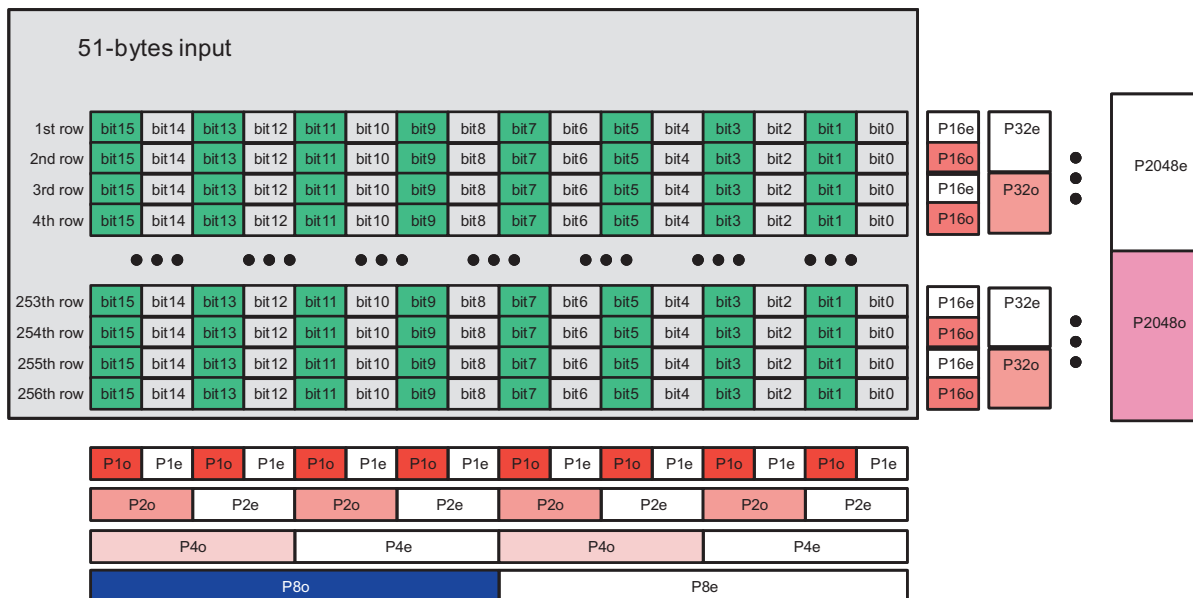

The parity computation based on 16-bit words affects the row and column parity mapping. The main difference is that the odd and even parity bits P8o and P8e are computed on rows for an 8-bit based ECC while there are computed on columns for a 16-bit based ECC. [Figure 15-84](#) and [Figure 15-85](#) show a 128 Word 16 ECC computation scheme and a 256 16-bit word ECC computation scheme.

Figure 15-85. 256 Word16 ECC Computation

gpmc-031

15.4.4.13.3.2 BCH Code (Bose-Chaudhuri-Hocquenghem)

All references to Error Code Correction (ECC) in this subsection refer to the 4- to 16-bit error correction BCH code.

15.4.4.13.3.2.1 Requirements

1. Read and write accesses to a NAND flash take place by whole pages, in a predetermined sequence: first the data byte page itself, then some spare bytes, including the BCH ECC (and other information). The NAND IC can cache a full page, including spares, for read and write accesses. Typical page write sequence:
 - Sequential write to NAND cache of main data + spare data, for a page. ECC is calculated on the fly. Calculated ECC may be inserted on the fly in the spares, or replaced by dummy accesses.
 - When the calculated ECC is replaced by dummy accesses, it must be written to the cache in a second, separate phase. The ECC module is disabled during that time.
 - NAND writes its cache line (page) to the array.
 Typical page read sequence:
 - Sequential read of a page. ECC is calculated on the fly.
 - ECC module buffers status determines the presence of errors.
2. Accesses to several memories may be interleaved by the GPMC, but only one of those memories can be a NAND using the BCH engine at a time; in other words, only one BCH calculation (for example, for a single page) can be on-going at any time. Note also that the sequential nature of NAND accesses guarantees that the data is always written / read out in the same order. BCH-relevant accesses are selected by the GPMCs chip-select.
3. Each page may hold up to 4 Kbytes of data, spare bytes not included. This means up to 8 x 512-byte BCH messages. Since all the data is written / read out first, followed by the BCH ECC, this means that the BCH engine must be able to hold 8 104-bit remainders or syndromes (or smaller, 52-bit ones) at the same time. The BCH module has the capacity to store all remainders internally. After the page start, an internal counter is used to detect the 512-byte sector boundaries. On those boundaries, the current remainder is stored and the divider reset for the next calculation. At the end of the page, the BCH module contains all remainders.
4. NAND access cycles hold 8 or 16 bits of data each (1 or 2 bytes); Each NAND cycle takes at least 4

cycles of the GPMCs internal clock. This means the NAND flash timing parameters must define a RDCYCLETIME and a WRCYCLETIME of at least 4 clock cycles after optimization when using the BCH calculator.

- The spare area is assumed to be large enough to hold the BCH ECC, that is, to have at least a message of 13 bytes available per 512-byte sector of data. The zone of unused spare area by the ECC may or may not be protected by the same ECC scheme, by extending the BCH message beyond 512 bytes (maximum codeword is 1023-byte long, ECC included, which leaves a lot of space to cover some spares bytes).

15.4.4.13.3.2.2 Memory-Mapping of the BCH Codeword

BCH encoding considers a block of data to protect as a polynomial message $M(x)$. In our standard case, 512 bytes of data (that is, 2^{12} bits = 4096 bits) are seen as a polynomial of degree $2^{12} - 1 = 4095$, with parameters ranging from M0 to M4095. For 512 bytes of data, 52 bits are required for 4-bit error correction, and 104 bits are required for 8-bit error correction and 207 bits are required for 16-bit error correction. The ECC is a remainder polynomial $R(x)$ of degree 103 (or 51, depending on the selected mode). The complete codeword $C(x)$ is the concatenation of $M(x)$ and $R(x)$ as shown in [Table 15-229](#).

Table 15-229. Flattened BCH Codeword Mapping (512 Bytes + 104 Bits)

| Bit number | Message M(x) | | | ECC R(x) | | |
|------------|--------------|-----|----|----------|-----|----|
| | M4095 | ... | M0 | R103 | ... | R0 |

If the message is extended by the addition of spare bytes to be protected by the same ECC, the principle is still valid. For example, a 3-byte extension of the message gives a polynomial message $M(x)$ of degree $((512 + 3) * 8) - 1 = 4119$, for a total of $3+13 = 16$ spare bytes of spare, all protected as part of the same codeword.

The message and the ECC bits are manipulated and mapped in the GPMC byte-oriented system. The ECC bits are stored in [GPMC_BCH_RESULT0_i](#), [GPMC_BCH_RESULT1_i](#), [GPMC_BCH_RESULT2_i](#), and [GPMC_BCH_RESULT3_i](#) (where $i = 0$ to 7).

15.4.4.13.3.2.2.1 Memory-Mapping of the Data Message

The data message mapping shall follow the following rules:

- Bit endianness within a byte is little-endian, that is, the bytes LS bit is also the lowest-degree polynomial parameter: a byte b7-b0 (with b0 the LS bit) represents a segment of polynomial $b7 * x^{(7+i)} + b6 * x^{(6+i)} + \dots + b0 * x^i$
- The message is mapped in the NAND starting with the highest-order parameters, that is, in the lowest addresses of a NAND page.
- Byte endianness within the NANDs 16-bit words is big endian. This means that the same message mapped in 8- and 16-bit memories has the same content at the same byte address.

NOTE: The BCH module has no visibility over actual addresses. The most important point is the sequence of data word the BCH sees. However, the NAND page is always scanned incrementally in read and write accesses, and this produces the mapping patterns described below.

The following tables represent the mapping of the same 512-byte vector (typically a BCH message) in the NANDs memory space. Note that the byte 'address' is only an offset modulo 512 (0x200), since the same page may contain several contiguous 512-byte sectors (BCH blocks). The LSB and MSB are respectively the bits M0 and $M(2^{12}-1)$ of the codeword mapping given above. In both cases the data vectors are aligned, that is, their boundaries coincide with the RAMs data word boundaries.

Table 15-230. Aligned Message Byte Mapping in 8-bit NAND

| Byte offset | 8-bit word |
|-------------|------------------------|
| 0x000 | (msb) Byte 511 (0x1FF) |
| 0x001 | Byte 510 (0x1FE) |
| ... | ... |
| 0x1FF | Byte 0 (0x0) (lsb) |

Table 15-231. Aligned Message Byte Mapping in 16-bit NAND

| Byte offset | 16-bit words MSB | 16-bit words LSB |
|-------------|------------------|------------------------|
| 0x000 | Byte 510 (0x1FE) | (msb) Byte 511 (0x1FF) |
| 0x002 | Byte 508 (0x1FC) | Byte 509 (0x1FD) |
| ... | ... | ... |
| 0x1FE | Byte 0 (0x0) | (lsb) Byte 1 (0x1) |

The following tables show the mapping in memory of arbitrarily-sized messages, starting on access (byte or 16-bit word) boundaries for more clarity. Note that message may actually start and stop on arbitrary nibbles. A nibble is a 4-bit entity. The unused nibbles are not discarded, and they can still be used by the BCH module, but as part of the next message section (for example, on another sectors ECC).

Table 15-232. Aligned Nibble Mapping of Message in 8-bit NAND

| Byte offset | 8-bit word | |
|-------------|-------------------------------|-------------------------------|
| | 4-bit most significant Nibble | 4-bit less significant Nibble |
| 1 | (msb) Nibble S-1 | Nibble S-2 |
| 2 | Nibble S-3 | Nibble S-4 |
| ... | ... | ... |
| S/2 - 2 | Nibble 3 | Nibble 2 |
| S/2 - 1 | Nibble 1 | Nibble 0 (lsb) |

Table 15-233. Misaligned Nibble Mapping of Message in 8-bit NAND

| Byte offset | 8-bit word | |
|---------------|-------------------------------|-------------------------------|

| $(S+3)/2 - 4$ | Nibble 2 | Nibble 1 | Nibble 4 | Nibble 3 |
| $(S+3)/2 - 2$ | | | Nibble 0 (lsb) | |

Note that many other cases exist than the ones represented above, for example, where the message does not start on a word boundary.

15.4.4.13.3.2.2 Memory-Mapping of the ECC

The ECC (or remainder) is presented by the BCH module as a single 104-bit (or 52-bit), little-endian vector. It is up to the software to fetch those 13 bytes (or 6 bytes) from the modules interface, then store them to the NANDs spare area (page write) or to an intermediate buffer for comparison with the stored ECC (page read). There are no constraints on the ECC mapping inside the spare area: it is a softwarecontrolled operation.

However, it is advised to maintain a coherence in the respective formats of the message or the ECC remainder once they have been read out of the NAND. The error correction algorithm works from the complete codeword (concatenated message and remainder) once an error as been detected. The creation of this codeword should be made as straightforward as possible.

There are cases where the same NAND access contains both data and the ECC protecting that data. This is the case when the data/ECC boundary (which can be on any nibble) does not coincide with an access boundary. The ECC is calculated on-the-fly following the write. In that case, the write must also contain part of the ECC because it is impossible to insert the ECC on-the-fly. Instead:

- During the initial page write (BCH encoding), the ECC is replaced by dummy bits. The BCH encoder is by definition turned OFF during the ECC section, so the BCH result is unmodified.
- During a second phase, the ECC is written to the correct location, next to the actual data.
- The completed line buffer is then written to the NAND array.

15.4.4.13.3.2.3 Wrapping Modes

For a given wrapping mode, the module automatically goes through a specific number of sections, as data is being fed into the module. For each section, the BCH core can be enabled (in which case the data is fed to the BCH divider) or not (in which case the BCH simply counts to the end of the section). When enabled, the data is added to the ongoing calculation for a given sector number (for example, number 0).

Wrapping modes are described below. To get a better understanding and see the real-life read and write sequences implemented with each mode, see [Section 15.4.4.13.3.2.3, Supported NAND Page Mappings and ECC Schemes](#).

For each mode:

- a sequence describes the mode in pseudo-language, with for each section the size and the buffer used for ECC processing (if ON). The programmable lengths are size, size0 and size1.
- a checksum condition is given. If the checksum condition is not respected for a given mode, the modules behavior is unpredictable. S is the number of sectors in the page; size0 and size1 are the section sizes programmed for the mode, in nibbles.

Note that wrapping modes 8, 9, 10, and 11 insert a 1-nibble padding where the BCH processing is OFF. This is intended for t = 4 ECC, where ECC is 6 bytes long and the ECC area is expected to include (at least) 1 unused nibble to remain byte-aligned.

15.4.4.13.3.2.4 Manual Mode (0x0)

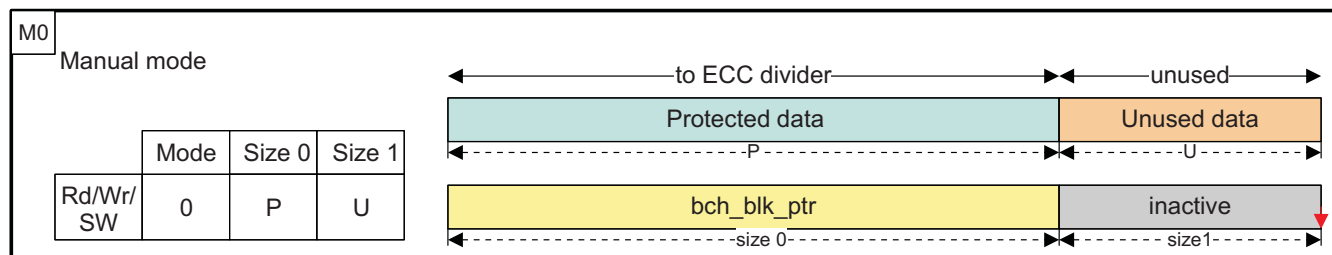

This mode is intended for short sequences, added manually to a given buffer through the software data port input. A complete page may be built out of several such sequences.

To process an arbitrary sequence of 4-bit nibbles, accesses to the software data port must be made, containing the appropriate data. If the sequence end does not coincide with an access boundary (for example, to process 5 nibbles = 20 bits in 16-bit access mode) and those nibbles need to be skipped, a number of unused nibbles must be programmed in [GPMC_ECC_SIZE_CONFIG\[29:22\] ECCSIZE1](#). (In the same example: 5 nibbles to process + 3 to discard = 8 nibbles = exactly 2 x 16-bit accesses. Software must set:

- [GPMC_ECC_SIZE_CONFIG\[19:12\] ECCSIZE0](#) = 0x5
- [GPMC_ECC_SIZE_CONFIG\[29:22\] ECCSIZE1](#) = 0x3

NOTE: In the following figures size and size0 are the same parameter.

Figure 15-86. Manual Mode Sequence and Mapping

gpmc-032

Section processing sequence:

- One time with buffer
 - size0 nibbles of data, processing ON
 - size1 nibbles of unused data, processing OFF

Checksum: size0 + size1 nibbles must fit in a whole number of accesses.

In the following sections, S is the number of sectors in the page.

15.4.4.13.3.2.2.5 Mode 0x1

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S × (size0 + size1)

15.4.4.13.3.2.2.6 Mode 0xA (10)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
 - 1 nibble pad spare, processing OFF
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S × (size0 + 1 + size1)

15.4.4.13.3.2.2.7 Mode 0x2

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $S \times (\text{size0} + \text{size1})$

15.4.4.13.3.2.2.8 Mode 0x3

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times \text{size1})$

15.4.4.13.3.2.2.9 Mode 0x7

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times \text{size1})$

15.4.4.13.3.2.2.10 Mode 0x8

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time with buffer 0
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times (1 + \text{size1}))$

15.4.4.13.3.2.2.11 Mode 0x4

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = $\text{size0} + (S \times \text{size1})$

15.4.4.13.3.2.2.12 Mode 0x9

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- One time (no buffer used)
 - size0 nibbles spare, processing OFF
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = size0 + (S × (1+size1))

15.4.4.13.3.2.2.13 Mode 0x5

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S × (size0 + size1)

15.4.4.13.3.2.2.14 Mode 0xB (11)

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat with buffer 0 to S-1
 - 1 nibble padding spare, processing OFF
 - size1 nibbles spare, processing ON

Checksum: Spare area size (nibbles) = S × (size0 + 1 + size1)

15.4.4.13.3.2.2.15 Mode 0x6

Page processing sequence:

- Repeat with buffer 0 to S-1
 - 512-byte data, processing ON
- Repeat with buffer 0 to S-1
 - size0 nibbles spare, processing ON
- Repeat S times (no buffer used)
 - size1 nibbles spare, processing OFF

Checksum: Spare area size (nibbles) = S × (size0 + size1)

15.4.4.13.3.2.3 Supported NAND Page Mappings and ECC Schemes

The following rules apply throughout the entire mapping description:

- Main data area (sectors) size is hardcoded to 512 bytes.
- Spare area size is programmable.
- All page sections (of main area data bytes, protected spare bytes, unprotected spare bytes, and ECC)

are defined as explained in [Section 15.4.4.13.3.2.2.1](#), *Memory-Mapping of the Data Message*.

Each one of the following sections shows a NAND page mapping example (per-sector spare mappings, pooled spare mapping, per-sector spare mapping, with ECC separated at the end of the page).

In the mapping diagrams, sections that belong to the same BCH codeword have the same color (blue or green); unprotected sections are not covered (orange) by the BCH scheme.

Below each mapping diagram, a write (encoding) and read (decoding: syndrome generation) sequence is given, with the number of the active buffers at each point in time (yellow). In the inactive zones (grey), no computing is taking place but the data counter is still active.

In [Figure 15-87](#) to [Figure 15-89](#), tables on the left summarize the mode, size0, size1 parameters to program for respectively write and read processing of a page, with the given mapping, where :

- P is the size of spare byte section Protected by the ECC (in nibbles)
- U is the size of spare byte section Unprotected by the ECC (in nibbles)
- E is the size of the ECC itself (in nibbles)
- S is the number of Sectors per page (2 in the current diagrams)

Each time the processing of a BCH block is complete (ECC calculation for write/encoding, syndrome generation for read/decoding, indicated by red arrows), the update pointer is pulsed. Note that the processing for block 0 can be the first or the last to complete, depending on the NAND page mapping and operation (read or write). All examples show a page size of 1kByte + spares, that is, S = 2 sectors of 512 bytes. The same principles can be extended to larger pages by adding more sectors.

The actual BCH codeword size is used during the error location work to restrict the search range: by definition, errors can only happen in the codeword that was actually written to the NAND, and not in the mathematical codeword of $n = 2^{13} - 1 = 8191$ bits. That codeword (higher-order bits) is all-zero and implicit during computations.

The actual BCH codeword size depends on the mode, on the programmed sizes and on the sector number (all sizes in nibbles):

- Spares mapped and protected per sector (below: see M1-M2-M3-M9-M10):
 - all sectors: (512) + P + E
- Spares pooled and protected by sector 0 (below: see M5-M6):
 - sector 0 codeword: (512) + P + E
 - other sectors: (512) + E
- Unprotected spares (below: see M4-M7-M8-M11-M12):
 - all codewords (512) + E

15.4.4.13.3.2.3.1 Per-Sector Spare Mappings

In these schemes, each 512-byte sector of the main area has its own dedicated section of the spare area. The spare area of each sector is composed of :

- ECC, which must be located after the data it protects
- other data, which may or may not be protected by the sectors ECC

Figure 15-87. NAND Page Mapping and ECC: Per-Sector Schemes

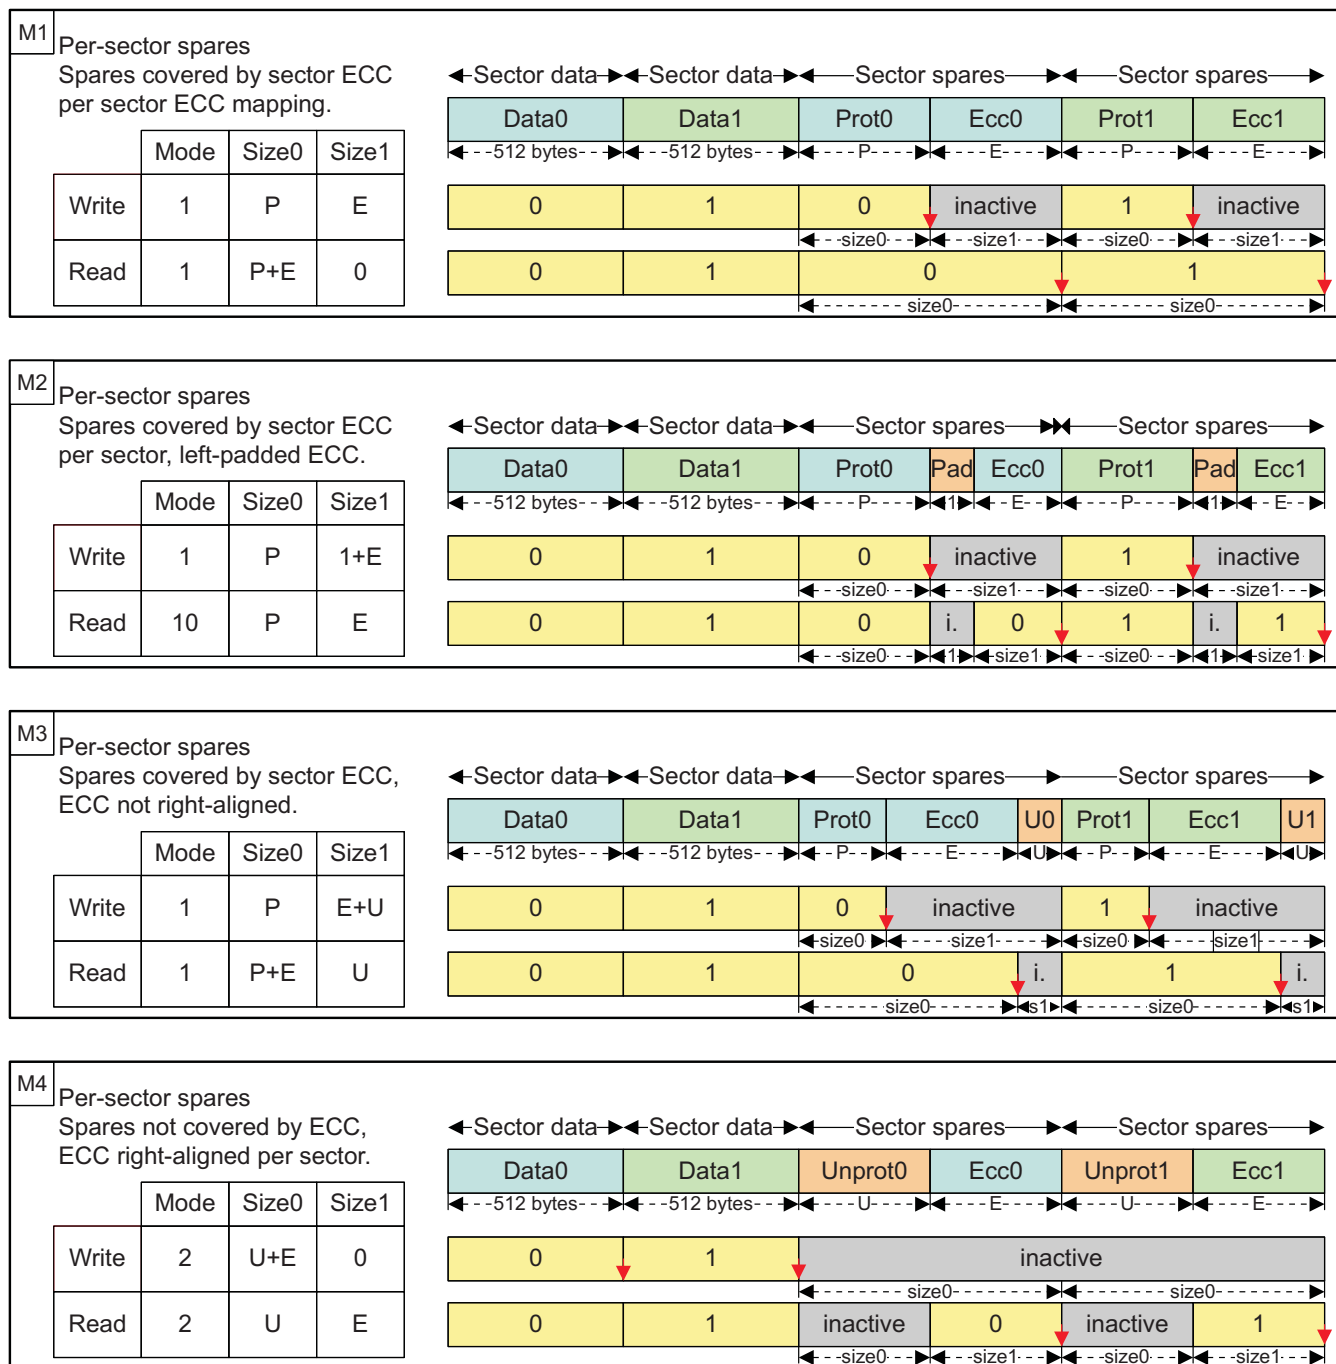

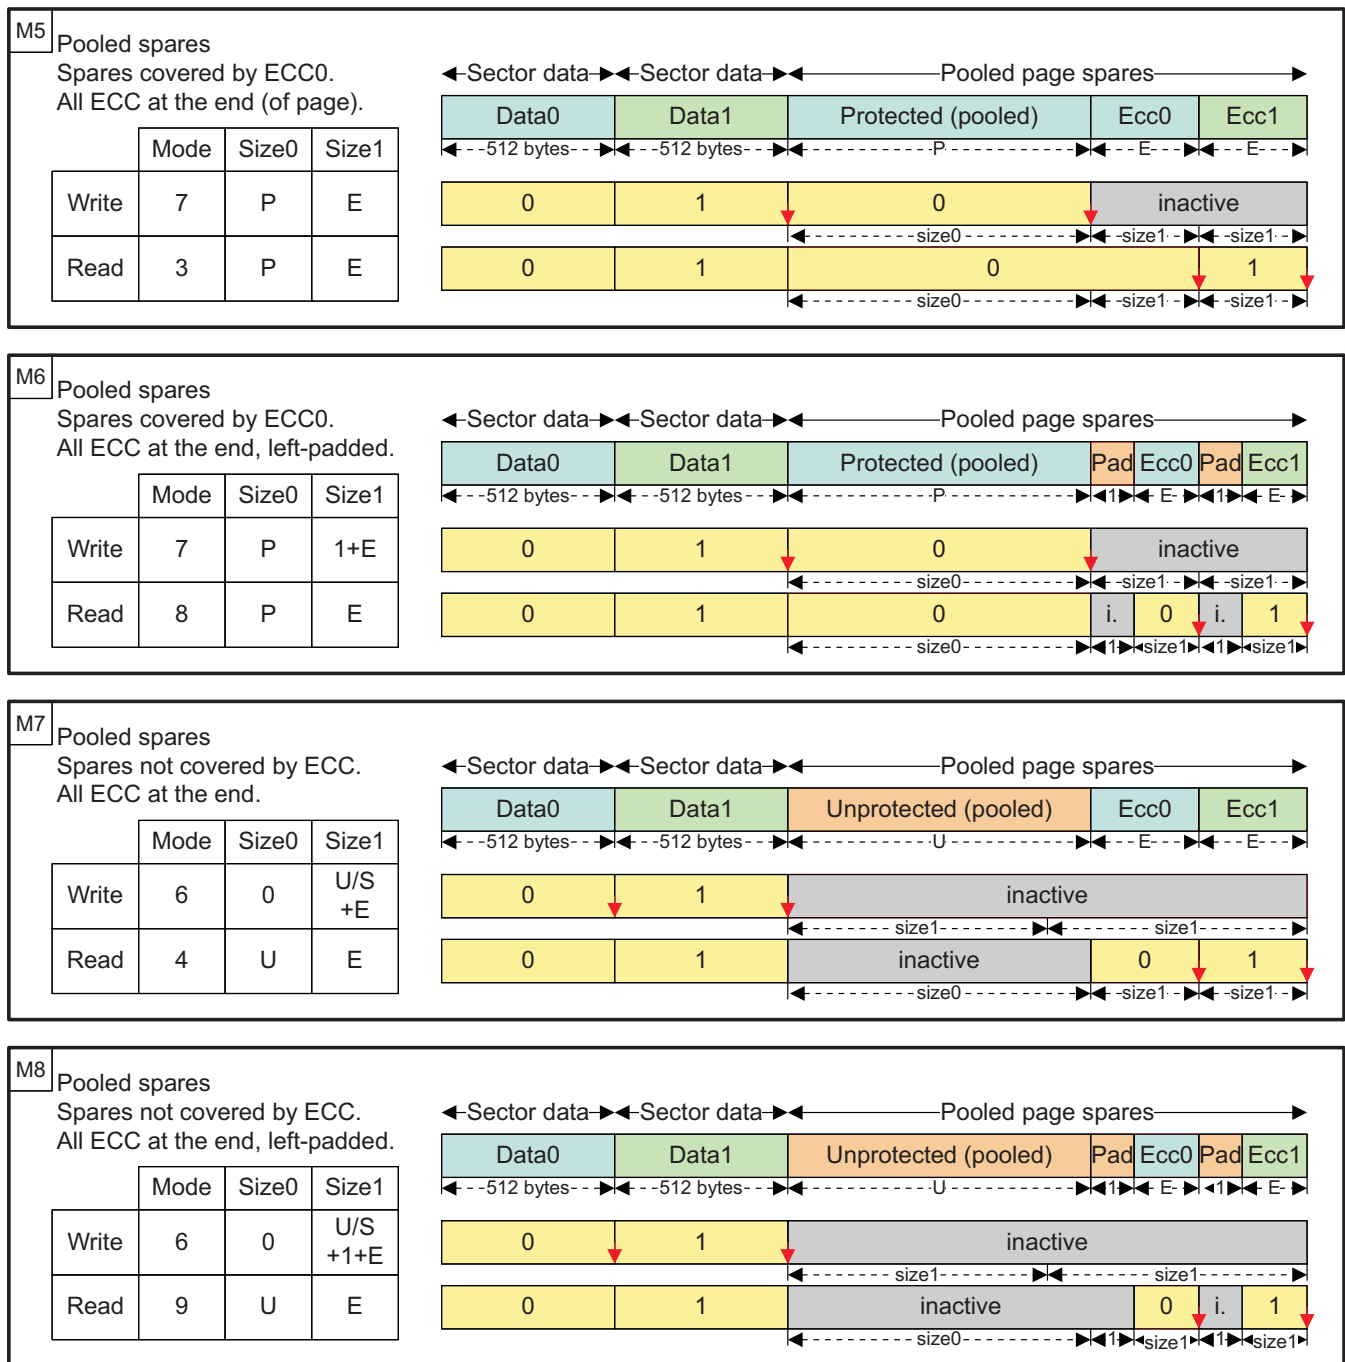

Figure 15-88. NAND Page Mapping and ECC: Pooled Spare Schemes

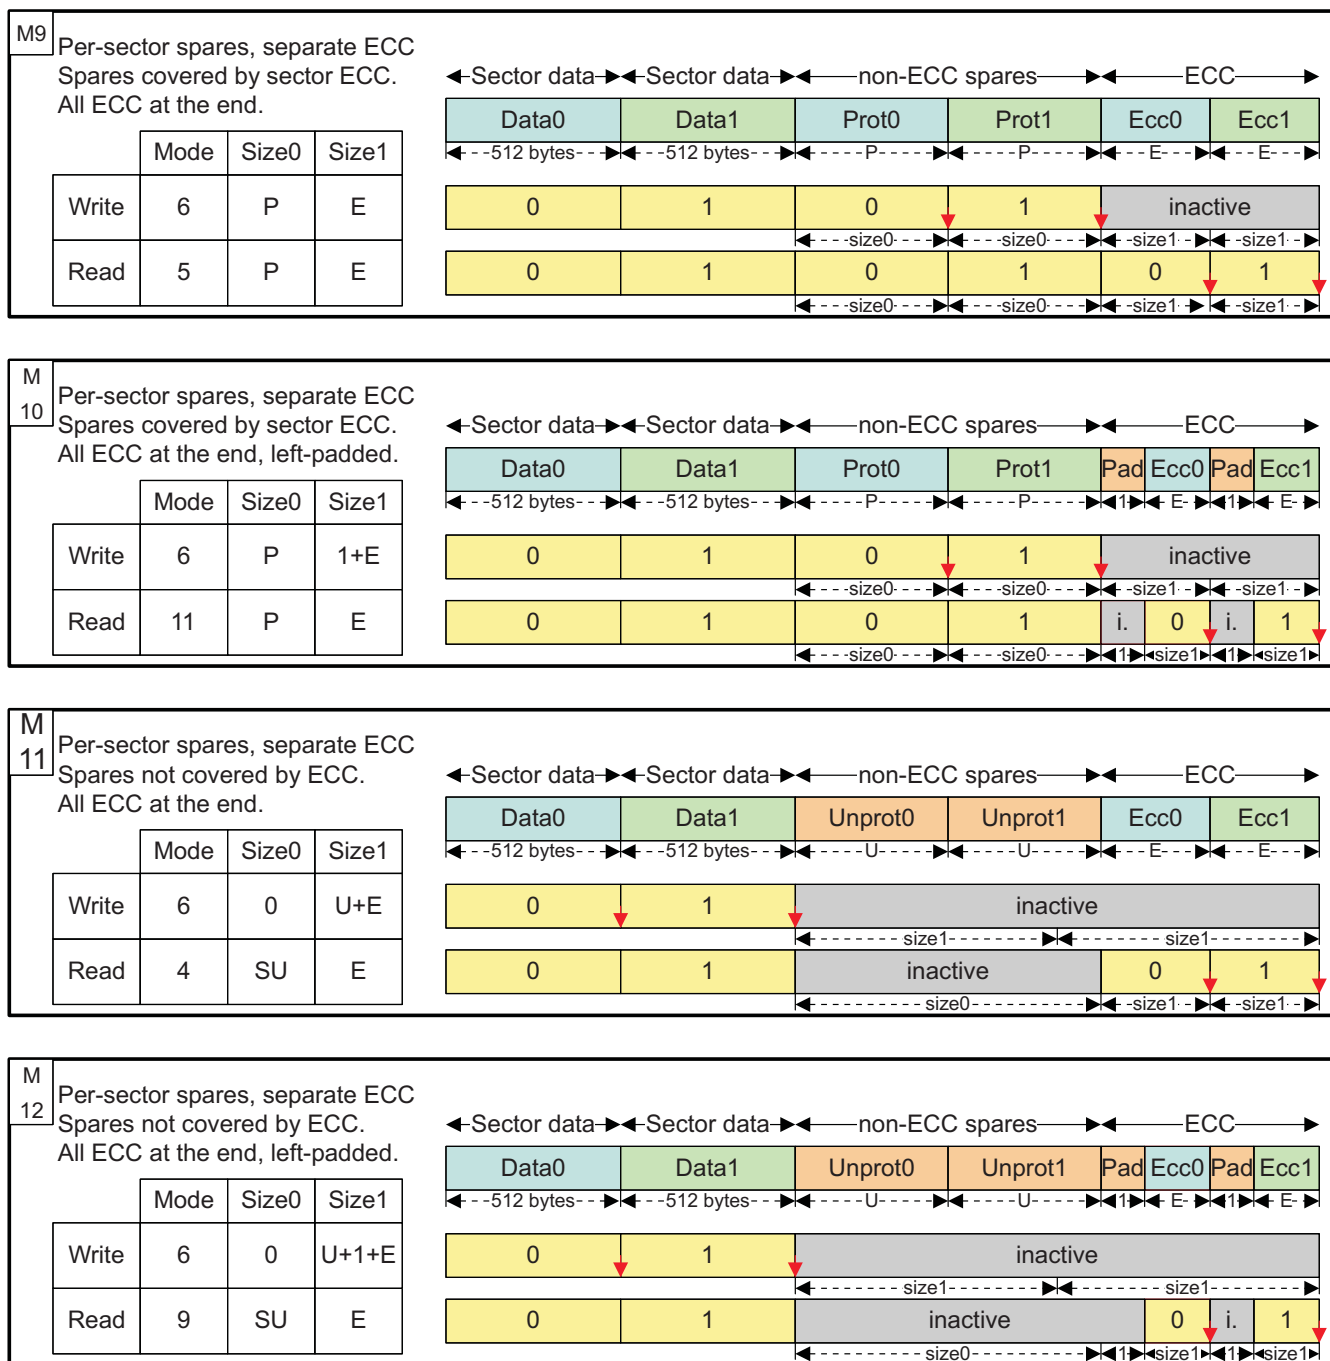

gpmc-034

15.4.4.13.3.2.3.3 Per-Sector Spare Mapping, with ECC Separated at the End of the Page

In these schemes, each 512-byte sector of the main area is associated with 2 sections of the spare area.

- ECC section, all aligned at the end of the page
- other data section, aligned before the ECCs, each of which may or may not be protected by its sectors ECC

Figure 15-89. NAND Page Mapping and ECC: Per-Sector Schemes, with Separate ECC

gpmc_035

15.4.4.13.4 Prefetch and Write-Posting Engine

NAND device data access cycles are usually much slower than the MPU system frequency; such NAND read or write accesses issued by the processor will impact the overall system performance, especially considering long read or write sequences required for NAND page loading or programming. To minimize this effect on system performance, the GPMC includes a prefetch and write-posting engine, which can be used to read from or write to any chip-select location in a buffered manner.

The prefetch and write-posting engine is a simplified embedded-access requester that presents requests to the access engine on a user-defined chip-select target. The access engine interleaves these requests with any request coming from the L3 interface; as a default the prefetch and write-posting engine has the lowest priority.

The prefetch and write-posting engine is dedicated to data-stream access (as opposed to random data access); thus, it is primarily dedicated to NAND support. The engine does not include an address generator; the request is limited to chip-select target identification. It includes a 64-byte FIFO associated with a DMA request synchronization line, for optimal DMA-based use.

The prefetch and write-posting engine uses an embedded 64 bytes (32 16-bit word) FIFO to prefetch data from the NAND device in read mode (prefetch mode) or to store host data to be programmed into the NAND device in write mode (write-posting mode). The FIFO draining and filling (read and write) can be controlled either by the MPU through interrupt synchronization (an interrupt is triggered whenever a programmable threshold is reached) or the sDMA through DMA request synchronization, with a programmable request byte size in both prefetch or posting mode.

The prefetch and write-posting engine includes a single memory pool. Therefore, only one mode, read or write, can be used at any given time. In other words, the prefetch and write-posting engine is a single-context engine that can be allocated to only one chip-select at a time for a read prefetch or a write-posting process.

The engine does not support atomic command and address phase programming and is limited to linear memory read or write access. In consequence, it is limited to NAND data-stream access. The engine relies on the MPU NAND software driver to control block and page opening with the correct data address pointer initialization, before the engine can read from or write to the NAND memory device.

Once started, the engine data reads and writes sequencing is solely based on FIFO location availability and until the total programmed number of bytes is read or written.

Any host-concurrent accesses to a different chip-select are correctly interleaved with ongoing engine accesses. The engine has the lowest priority access so that host accesses to a different chip-select do not suffer a large latency.

A round-robin arbitration scheme can be enabled to ensure minimum bandwidth to the prefetch and write-posting engine in the case of back-to-back direct memory requests to a different chip-select. If the [GPMC_PREFETCH_CONFIG1\[23\]](#) PFPWENROUNDROBIN bit is enabled, the arbitration grants the prefetch and write posting engine access to the GPMC bus for a number of requests programmed in the [GPMC_PREFETCH_CONFIG1\[19:16\]](#) PFPWWEIGHTEDPRIO field.

The prefetch/write-posting engine read or write request is routed to the access engine with the chip-select destination ID. After the required arbitration phase, the access engine processes the request as a single access with the data access size equal to the device size specified in the corresponding chip-select configuration.

NOTE: The destination chip-select configuration must be set to the NAND protocol-compatible configuration for which address lines are not used (the address bus is not changed from its current value). Selecting a different chip-select configuration can produce undefined behavior.

15.4.4.13.4.1 General Facts About the Engine Configuration

The engine can be configured only if the [GPMC_PREFETCH_CONTROL\[0\]](#) STARTENGINE bit is deasserted.

The engine must be correctly configured in prefetch or write-posting mode and must be linked to a NAND chip-select before it can be started. The chip-select is linked using the [GPMC_PREFETCH_CONFIG1\[26:24\]](#) ENGINECSSELECTOR field.

In both prefetch and write-posting modes, the engine respectively uses byte or 16-bit word access requests for an 8- or 16-bit-wide NAND device attached to the linked chip-select. The FIFOTHRESHOLD and TRANSFERCOUNT fields must be programmed accordingly as a number of bytes.

When the [GPMC_PREFETCH_CONFIG1\[7\] ENABLEENGINE](#) bit is set, the FIFO entry on the L3 interconnect port side is accessible at any address in the associated chip-select memory region. When the [ENABLEENGINE](#) bit is set, any host access to this chip-select is rerouted to the FIFO input. Directly accessing the NAND device linked to this chip-select from the host is still possible through the [GPMC_NAND_COMMAND_i](#), [GPMC_NAND_ADDRESS_i](#), and [GPMC_NAND_DATA_i](#) registers (where $i = 0$ to 7).

The FIFO entry on the L3 interconnect port can be accessed with byte, 16-bit word, or 32-bit word access size, according to little-endian format, even though the FIFO input is 32 bits wide.

The FIFO control is made easier through the use of interrupts or DMA requests associated with the [FIFOTHRESHOLD](#) bit field. The [GPMC_PREFETCH_STATUS\[30:24\] FIFOPointer](#) field monitors the number of available bytes to be read in prefetch mode or the number of free empty slots which can be written in write-posting mode. The [GPMC_PREFETCH_STATUS\[13:0\] COUNTVALUE](#) field monitors the number of remaining bytes to be read or written by the engine according to the [TRANSFERCOUNT](#) value. The [FIFOPointer](#) and [COUNTVALUE](#) bit fields are always expressed as a number of bytes even if a 16-bit wide NAND device is attached to the linked chip-select.

In prefetch mode, when the [FIFOPointer](#) equals 0, that is, the FIFO is empty, a host read access receives the byte last read from the FIFO as its response. In case of 32-bit word or 16-bit word read accesses, the last byte read from the FIFO is copied the required number of times to fit the requested word size. In write-posting mode, when the [FIFOPointer](#) equals 0, that is, the FIFO is full, a host write overwrites the last FIFO byte location. There is no underflow or overflow error reporting in the GPMC.

15.4.4.13.4.2 Prefetch Mode

The prefetch mode is selected when the [GPMC_PREFETCH_CONFIG1\[0\] ACCESSMODE](#) bit is cleared.

The MPU NAND software driver must issue the block and page opening (READ) command with the correct data address pointer initialization before the engine can be started to read from the NAND memory device. The engine is started by asserting the [GPMC_PREFETCH_CONTROL\[0\] STARTENGINE](#) bit. The [STARTENGINE](#) bit automatically clears when the prefetch process completes.

If required, the ECC calculator engine must be initialized (that is, reset, configured, and enabled) before the prefetch engine is started, so that the ECC is correctly computed on all data read by the prefetch engine.

When the [GPMC_PREFETCH_CONFIG1\[3\] SYNCHROMODE](#) bit is cleared, the prefetch engine starts requesting data as soon as the [STARTENGINE](#) bit is set. If using this configuration, the host must monitor the NAND device-ready pin so that it only sets the [STARTENGINE](#) bit when the NAND device is in a ready state, meaning data is valid for prefetching.

When the [SYNCHROMODE](#) bit is set, the prefetch engine starts requesting data when an active to inactive wait signal transition is detected. The transition detector must be cleared before any transition detection; see [Section 15.4.4.13.2.2, Ready Pin Monitored by Hardware Interrupt](#). The [GPMC_PREFETCH_CONFIG1\[5:4\] WAITPINSELECTOR](#) field selects which `gpmc_wait` pin edge detector triggers the prefetch engine in this synchronized mode.

If the [STARTENGINE](#) bit is set after the NAND address phase (page opening command), the engine is effectively started only after the actual NAND address phase completion. To prevent GPMC stall during this NAND address phase, set the [STARTENGINE](#) bit field before NAND address phase completion when in synchronized mode. The prefetch engine will start when an active to inactive wait signal transition is detected. The [STARTENGINE](#) bit is automatically cleared on prefetch process completion.

The prefetch engine issues a read request to fill the FIFO with the amount of data specified by [GPMC_PREFETCH_CONFIG2\[13:0\] TRANSFERCOUNT](#) field.

Table 15-238. Prefetch Mode Configuration

| Bit Field | Register | Value | Comments |
|------------------|----------------------------------------------|--------|--------------------------------------------------------------------------------------------|
| STARTENGINE | GPMC_PREFETCH_CONTROL[0] | 0 | Prefetch engine can be configured only if STARTENGINE is set to 0. |
| ENGINECSSELECTOR | GPMC_PREFETCH_CONFIG1[26:24] | 0 to 3 | Selects the chip-select associated with a NAND device where the prefetch engine is active. |

Table 15-238. Prefetch Mode Configuration (continued)

| Bit Field | Register | Value | Comments |
|-----------------------|-----------------------------------------------|--------|-----------------------------------------------------------------------------------------------------------------|
| ACCESSMODE | GPMC_PREFETCH_CONFIG1 [0] | 0 | Selects prefetch mode |
| FIFOTHRESHOLD | GPMC_PREFETCH_CONFIG1 [14:8] | | Selects the maximum number of bytes read or written by the host on DMA or interrupt request |
| TRANSFERCOUNT | GPMC_PREFETCH_CONFIG2 [13:0] | | Selects the number of bytes to be read or written by the engine to the selected chip-select |
| SYNCHROMODE | GPMC_PREFETCH_CONFIG1 [3] | 0/1 | Selects when the engine starts the access to the chip-select |
| WAITPINSELECT | GPMC_PREFETCH_CONFIG1 [17:16] | 0 to 1 | Selects wait pin edge detector (if GPMC_PREFETCH_CONFIG1 [3] SYNCHROMODE = 0x1) |
| ENABLEOPTIMIZEDACCESS | GPMC_PREFETCH_CONFIG1 [27] | 0/1 | See Section 15.4.4.13.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine . |
| CYCLEOPTIMIZATION | GPMC_PREFETCH_CONFIG1 [30:28] | | Number of clock cycle removed to timing parameters |
| ENABLEENGINE | GPMC_PREFETCH_CONFIG1 [7] | 1 | Engine enabled |
| STARTENGINE | GPMC_PREFETCH_CONTROL [0] | 1 | Starts the prefetch engine |

15.4.4.13.4.3 FIFO Control in Prefetch Mode

The FIFO can be drained directly by the MPU or by an sDMA channel.

In MPU draining mode, the FIFO status can be monitored through the [GPMC_PREFETCH_STATUS](#)[30:24] FIFOPINTER field or through the [GPMC_PREFETCH_STATUS](#)[16] FIFOTHRESHOLDSTATUS bit. The FIFOPINTER indicates the current number of available data to be read; FIFOTHRESHOLDSTATUS set to 1 indicates that at least FIFOTHRESHOLD bytes are available from the FIFO.

An interrupt can be triggered by the GPMC if the [GPMC_IRQENABLE](#)[0] FIFOEVENTENABLE bit is set. The FIFO interrupt event is logged, and the [GPMC_IRQSTATUS](#)[0] FIFOEVENTSTATUS bit is set. To clear the interrupt, the MPU must read all the available bytes, or at least enough bytes to get below the programmed FIFO threshold, and the FIFOEVENTSTATUS bit must be cleared to enable further interrupt events. The FIFOEVENTSTATUS bit must always be reset prior to asserting the FIFOEVENTENABLE bit to clear any out-of-date logged interrupt event. This interrupt generation must be enabled after enabling the STARTENGINE bit.

Prefetch completion can be monitored through the [GPMC_PREFETCH_STATUS](#)[13:0] COUNTVALUE field. COUNTVALUE indicates the number of currently remaining data to be requested according to the TRANSFERCOUNT value. An interrupt can be triggered by the GPMC when the prefetch process is complete (that is, COUNTVALUE equals 0) if the [GPMC_IRQENABLE](#)[1] TERMINALCOUNTEVENTENABLE bit is set. At prefetch completion, the TERMINALCOUNT interrupt event is also logged, and the [GPMC_IRQSTATUS](#)[1] TERMINALCOUNTSTATUS bit is set. To clear the interrupt, the MPU must clear the TERMINALCOUNTSTATUS bit. The TERMINALCOUNTSTATUS bit must always be cleared prior to asserting the TERMINALCOUNTEVENTENABLE bit to clear any out-of-date logged interrupt event.

NOTE: The COUNTVALUE value is only valid when the prefetch engine is active (started), and an interrupt is only triggered when COUNTVALUE reaches 0, that is, when the prefetch engine automatically goes from an active to an inactive state.

The number of bytes to be prefetched (programmed in TRANSFERCOUNT) must be a multiple of the programmed FIFOTHRESHOLD to trigger the correct number of interrupts allowing a deterministic and transparent FIFO control. If this guideline is respected, the number of ISR accesses is always required and the FIFO is always empty after the last interrupt is triggered. In other cases, the TERMINALCOUNT interrupt must be used to read the remaining bytes in the FIFO (the number of remaining bytes being lower than the FIFOTHRESHOLD value).

In DMA draining mode, the [GPMC_PREFETCH_CONFIG1\[2\]](#) DMAMODE bit must be set so that the GPMC issues a DMA hardware request when at least FIFOTHRESHOLD bytes are ready to be read from the FIFO. The DMA channel owning this DMA request must be programmed so that the number of bytes programmed in FIFOTHRESHOLD is read from the FIFO during the DMA request process. The DMA request is kept active until this number of bytes has effectively been read from the FIFO, and no other DMA request can be issued until the ongoing active request is complete.

In prefetch mode, the TERMINALCOUNT event is also a source of DMA requests if the number of bytes to be prefetched is not a multiple of FIFOTHRESHOLD, the remaining bytes in the FIFO can be read by the DMA channel using the last DMA request. This assumes that the number of remaining bytes to be read is known and controlled through the DMA channel programming model.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (the STARTENGINE bit is set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that the out-of-date active DMA request does not trigger spurious DMA transfers.

15.4.4.13.4.4 Write-Posting Mode

The write-posting mode is selected when the [GPMC_PREFETCH_CONFIG1\[0\]](#) ACCESSMODE bit is set.

The MPU NAND software driver must issue the correct address pointer initialization command (page program) before the engine can start writing data into the NAND memory device. The engine starts when the [GPMC_PREFETCH_CONTROL\[0\]](#) STARTENGINE bit is set to 1. The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion (adding ECC handling, if required).

If used, the ECC calculator engine must be started (configured, reset, and enabled) before the posting engine is started so that the ECC parities are properly calculated on all data written by the prefetch engine to the associated chip-select.

In write-posting mode, the [GPMC_PREFETCH_CONFIG1\[3\]](#) SYNCHROMODE bit must be cleared so that posting starts as soon as the STARTENGINE bit is set and the FIFO is not empty.

If the STARTENGINE bit is set after the NAND address phase (page program command), the STARTENGINE setting is effective only after the actual NAND command completion. To prevent GPMC stall during this NAND command phase, set the STARTENGINE bit field before the NAND address completion and ensure that the associated DMA channel is enabled after the NAND address phase.

The posting engine issues a write request when valid data are available from the FIFO and until the programmed [GPMC_PREFETCH_CONFIG2\[13:0\]](#) TRANSFERCOUNT accesses have been completed.

The STARTENGINE bit clears automatically when posting completes. When all data have been written to the NAND memory device, the MPU NAND software driver must issue the second cycle program command and monitor the status for programming process completion. The closing program command phase must only be issued when the full NAND page has been written into the NAND flash write buffer, including the spare area data and the ECC parities, if used.

Table 15-239. Write-Posting Mode Configuration

| Bit Field | Register | Value | Comments |
|------------------|----------------------------------------------|--------|-------------------------------------------------------------------------------------------|
| STARTENGINE | GPMC_PREFETCH_CONTROL[0] | 0 | Write-posting engine can be configured only if STARTENGINE is set to 0. |
| ENGINECSSELECTOR | GPMC_PREFETCH_CONFIG1[26:24] | 0 to 3 | Selects the chip-select associated with a NAND device where the prefetch engine is active |

Table 15-239. Write-Posting Mode Configuration (continued)

| Bit Field | Register | Value | Comments |
|-----------------------|-----------------------------------------------|-------|----------------------------------------------------------------------------------------------------------------|
| ACCESSMODE | GPMC_PREFETCH_CONFIG1 [0] | 1 | Selects write-posting mode |
| FIFOTHRESHOLD | GPMC_PREFETCH_CONFIG1 [14:8] | | Selects the maximum number of bytes read or written by the host on DMA or interrupt request |
| TRANSFERCOUNT | GPMC_PREFETCH_CONFIG2 [13:0] | | Selects the number of bytes to be read or written by the engine from/to the selected chip-select |
| SYNCHROMODE | GPMC_PREFETCH_CONFIG1 [3] | 0 | Engine starts the access to chip-select as soon as STARTENGINE is set. |
| ENABLEOPTIMIZEDACCESS | GPMC_PREFETCH_CONFIG1 [27] | 0/1 | See Section 15.4.4.13.4.6, Optimizing NAND Access Using the Prefetch and Write-Posting Engine. |
| CYCLOPTIMIZATION | GPMC_PREFETCH_CONFIG1 [30:28] | | |
| ENABLEENGINE | GPMC_PREFETCH_CONFIG1 [7] | 1 | Engine enabled |
| STARTENGINE | GPMC_PREFETCH_CONTROL [0] | 1 | Starts the prefetch engine |

15.4.4.13.4.5 FIFO Control in Write-Posting Mode

The FIFO can be filled directly by the MPU or by an sDMA channel.

In MPU filling mode, the FIFO status can be monitored through the [FIFOPOINTER](#) or through the [GPMC_PREFETCH_STATUS](#)[16] [FIFOTHRESHOLDSTATUS](#) bit. [FIFOPOINTER](#) indicates the current number of available free byte places in the FIFO, and the [FIFOTHRESHOLDSTATUS](#) bit, when set, indicates that at least [FIFOTHRESHOLD](#) free byte places are available in the FIFO.

An interrupt can be issued by the GPMC if the [GPMC_IRQENABLE](#)[0] [FIFOEVENTENABLE](#) bit is set. When the interrupt is fired, the [GPMC_IRQSTATUS](#)[0] [FIFOEVENTSTATUS](#) bit is set. To clear the interrupt, the MPU must write enough bytes to fill the FIFO, or enough bytes to get below the programmed threshold, and the [FIFOEVENTSTATUS](#) bit must be cleared to get further interrupt events. The [FIFOEVENTSTATUS](#) bit must always be cleared prior to asserting the [FIFOEVENTENABLE](#) bit to clear any out-of-date logged interrupt event. This interrupt must be enabled after enabling the [STARTENGINE](#) bit.

The posting completion can be monitored through the [GPMC_PREFETCH_STATUS](#)[13:0] [COUNTVALUE](#) field. [COUNTVALUE](#) indicates the current number of remaining data to be written based on the [TRANSFERCOUNT](#) value. An interrupt is issued by the GPMC when the write-posting process completes (that is, [COUNTVALUE](#) equal to 0) if the [GPMC_IRQENABLE](#)[1] [TERMINALCOUNTEVENTENABLE](#) bit is set. When the interrupt is fired, the [GPMC_IRQSTATUS](#)[1] [TERMINALCOUNTSTATUS](#) bit is set. To clear the interrupt, the MPU must clear the [TERMINALCOUNTSTATUS](#) bit. The [TERMINALCOUNTSTATUS](#) bit must always be cleared prior to asserting the [TERMINALCOUNTEVENTENABLE](#) bit to clear any out-of-date logged interrupt event.

NOTE: The [COUNTVALUE](#) value is only valid if the write-posting engine is active and started, and an interrupt is only issued when [COUNTVALUE](#) reaches 0, that is, when the posting engine automatically goes from active to inactive.

In DMA filling mode, the [DMAMode](#) bit field in the [GPMC_PREFETCH_CONFIG1](#)[2] [DMAMODE](#) bit must be set so that the GPMC issues a DMA hardware request when at least [FIFOTHRESHOLD](#) bytes-free places are available in the FIFO. The DMA channel owning this DMA request must be programmed so that a number of bytes equal to the value programmed in the [FIFOTHRESHOLD](#) bit field are written into the FIFO during the DMA access. The DMA request remains active until the associated number of bytes has effectively been written into the FIFO, and no other DMA request can be issued until the ongoing active request has been completed.

Any potentially active DMA request is cleared when the prefetch engine goes from inactive to active prefetch (STARTENGINE set to 1). The associated DMA channel must always be enabled by the MPU after setting the STARTENGINE bit so that an out-of-date active DMA request does not trigger spurious DMA transfers.

In write-posting mode, the DMA or the MPU fill the FIFO with no consideration to the associated byte enables. Any byte stored in the FIFO is written into the memory device.

15.4.4.13.4.6 Optimizing NAND Access Using the Prefetch and Write-Posting Engine

Access time to a NAND memory device can be optimized for back-to-back accesses if the associated nCS signal is not deasserted between accesses. The GPMC access engine can track prefetch engine accesses to optimize the access timing parameter programmed for the allocated chip-select, if no accesses to other chip-selects (that is, interleaved accesses) occur. Similarly, the access engine also eliminates the CYCLE2CYCLEDELAY even if CYCLE2CYCLESAMECSEN is set. This capability is limited to the prefetch and write-posting engine accesses, and MPU accesses to a NAND memory device (through the defined chip-select memory region or through the [GPMC_NAND_DATA_i](#) location, $i = 0$ to 7) are never optimized.

The [GPMC_PREFETCH_CONFIG1](#)[27] ENABLEOPTIMIZEDACCESS bit must be set to enable optimized accesses. To optimize access time, the [GPMC_PREFETCH_CONFIG1](#)[30:28] CYCLEOPTIMIZATION field defines the number of GPMC_FCLK cycles to be suppressed from the RDCYCLETIME, WRCYCLETIME, RDACCESSTIME, WRACCESSTIME, CSOFFTIME, ADVOFFTIME, OEOFFTIME, and WEOFFTIME timing parameters.

[Figure 15-90](#) highlights that, in the case of back-to-back accesses to the NAND flash through the prefetch engine, CYCLE2CYCLESAMECSEN is forced to 0 when using optimized accesses. The first access uses the regular timing settings for this chip-select. All accesses after this one use settings reduced by x clock cycles, x being defined by the [GPMC_PREFETCH_CONFIG1](#)[30:28] CYCLEOPTIMIZATION field.

Figure 15-90. NAND Read Cycle Optimization Timing Description

gpmc-036

15.4.4.13.4.7 Interleaved Accesses Between Prefetch and Write-Posting Engine and Other Chip-Selects

Any on-going read or write access from the prefetch and write-posting engine is completed before an access to any other chip-select can be initiated. As a default, the arbiter uses a fixed-priority algorithm, and the prefetch and write-posting engine has the lowest priority. The maximum latency added to access starting time in this case equals the RDCYCLETIME or WRCYCLETIME (optimized or not) plus the requested BUSTURNAROUND delay for bus turnaround completion programmed for the chip-select to which the NAND device is connected to.

Alternatively, a round-robin arbitration can be used to prioritize accesses to the external bus. This arbitration scheme is enabled by setting the GPMC_PREFETCH_CONFIG1[23] PFPWENROUNDROBIN bit. When a request to another chip-select is received while the prefetch and write-posting engine is active, priority is given to the new request. The request processed thereafter is the prefetch and write-posting engine request, even if another interconnect request is passed in the mean time. The engine keeps control of the bus for an additional number of requests programmed in the GPMC_PREFETCH_CONFIG1[19:16] PFPWWEIGHTEDPRIO bit field. Control is then passed to the direct interconnect request.

As an example, the round-robin arbitration scheme is selected with PFPWWEIGHTEDPRIO set to 0x2. Considering the prefetch and write-posting engine and the interconnect interface are always requesting access to the external interface, the GPMC grants priority to the direct interconnect access for one request. The GPMC then grants priority to the engine for three requests, and finally back to the direct interconnect access, until the arbiter is reset when one of the two initiators stops initiating requests.

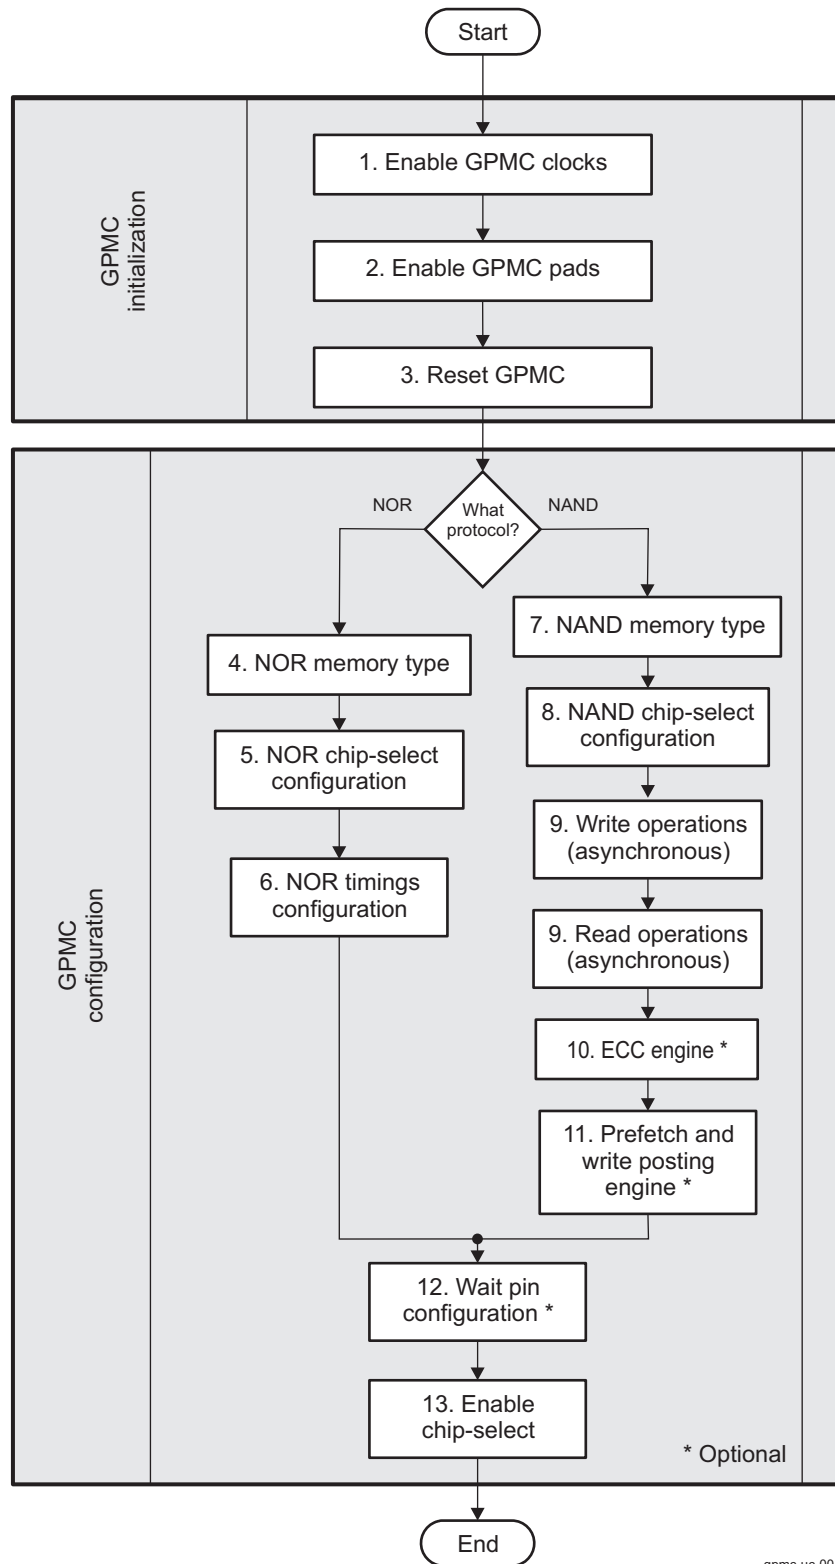

15.4.5 GPMC Basic Programming Model

15.4.5.1 GPMC High-Level Programming Model Overview

The goal of the basic high-level programming model is to introduce a top down approach to users that need to configure the GPMC module.

[Figure 15-91](#), [Table 15-240](#), [Table 15-241](#) and [Table 15-242](#) show a programming model top level diagram for the GPMC, and the description of each step. Each block of the diagram is detailed in one of the following subsections through a set of registers to configure.

Figure 15-91. Programming Model Top Level Diagram

gpmc-uc-001

Table 15-240. GPMC Initialization

| Step | Description |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|
| Enable GPMC clocks | Module interface and functional clocks must be enabled. See Chapter 3, Power, Reset, and Clock Management . |
| Enable GPMC pads | Module-specific pad muxing and configuration must be set in the control module. See Chapter 18, Control Module . |
| Reset GPMC | See Table 15-243 |

Table 15-241. GPMC Configuration in NOR Mode

| Step | Description |
|-------------------------------|----------------------------------|
| NOR Memory Type | See Table 15-244 |
| NOR Chip-Select Configuration | See Table 15-245 |
| NOR Timings Configuration | See Table 15-246 |
| Wait Pin Configuration | See Table 15-254 |
| Enable Chip-Select | See Table 15-255 |

Table 15-242. GPMC Configuration in NAND Mode

| Step | Description |
|-----------------------------------|----------------------------------|
| NAND Memory Type | See Table 15-249 |
| NAND Chip-Select Configuration | See Table 15-250 |
| Write Operations (Asynchronous) | See Table 15-251 |
| Read Operations (Asynchronous) | See Table 15-251 |
| ECC Engine | See Table 15-252 |
| Prefetch and Write-Posting Engine | See Table 15-253 |
| Wait Pin Configuration | See Table 15-254 |
| Enable Chip-Select | See Table 15-255 |

15.4.5.2 GPMC Initialization

[Table 15-271](#) describes the settings required to prepare the GPMC, that is enabling its clock, its pads, and proceeding to a GPMC reset.

Table 15-243. Reset GPMC

| Sub-process Name | Register / Bit Field | Value |
|------------------------|------------------------------------------------|-------|
| Start a software reset | GPMC_SYSCONFIG [1] SOFTRESET | 0x1 |
| Wait until | GPMC_SYSSTATUS [0] RESETDONE = | 0x1 |

15.4.5.3 GPMC Configuration in NOR Mode

This section gives a generic configuration for parameters related to the NOR memory connected to the GPMC.

Table 15-244. NOR Memory Type

| Sub-process Name | Register / Bit Field | Value |
|--------------------------------------------------|--------------------------------------------------------------------------|-------|
| Set the NOR protocol | GPMC_CONFIG1 _ <i>i</i> [11:10] DEVICETYPE | 0x0 |
| Set a device size | GPMC_CONFIG1 _ <i>i</i> [13:12] DEVICESIZE | x |
| Select an address and data multiplexing protocol | GPMC_CONFIG1 _ <i>i</i> [9] MUXADDDATA | x |
| Set the attached device page length | GPMC_CONFIG1 _ <i>i</i> [24:23] ATTACHEDDEVICEPAGELENGTH | x |
| Set the wrapping burst capabilities | GPMC_CONFIG1 _ <i>i</i> [31] WRAPBURST | x |

Table 15-244. NOR Memory Type (continued)

| Sub-process Name | Register / Bit Field | Value |
|--------------------------------------------------------------------|-----------------------------------------|-------|
| Select a timing signals latencies factor | GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY | x |
| Select an output clock frequency ⁽¹⁾ | GPMC_CONFIG1_i[1:0] GPMCFCLKDIVIDER | x |
| Choose an output clock activation time ⁽¹⁾ | GPMC_CONFIG1_i[26:25] CLKACTIVATIONTIME | x |
| Set a single or multiple access for read operations ⁽¹⁾ | GPMC_CONFIG1_i[30] READMULTIPLE | x |
| Set a synchronous or asynchronous mode for read operations | GPMC_CONFIG1_i[29] READTYPE | x |
| Set a single or multiple access for write operations | GPMC_CONFIG1_i[28] WRITEMULTIPLE | x |
| Set a synchronous or asynchronous mode for write operations | GPMC_CONFIG1_i[27] WRITETYPE | x |

⁽¹⁾ Only applies to synchronous configurations (or non-multiplexed async for the multiple access one).

Table 15-245. NOR Chip-Select Configuration

| Sub-process Name | Register / Bit Field | Value |
|-------------------------------------|----------------------------------|-------|
| Select the chip-select base address | GPMC_CONFIG7_i[5:0] BASEADDRESS | x |
| Select the chip-select mask address | GPMC_CONFIG7_i[11:8] MASKADDRESS | x |

Table 15-246. NOR Timings Configuration

| Sub-process Name | Register / Bit Field | Value |
|--------------------------------------------------------------|--------------------------------------------------------------|-------|
| Configure adequate timing parameters in various memory modes | See Section 15.4.5.6, GPMC Timing Parameters | |

Table 15-247. Wait Pin Configuration

| Sub-process Name | Register / Bit Field | Value |
|------------------------------------------------------------|------------------------------------------|-------|
| Enable or disable wait pin monitoring for read operations | GPMC_CONFIG1_i[22] WAITREADMONITORING | x |
| Enable or disable wait pin monitoring for write operations | GPMC_CONFIG1_i[21] WAITWRITEMONITORING | x |
| Select a wait pin monitoring time | GPMC_CONFIG1_i[19:18] WAITMONITORINGTIME | x |
| Choose the input wait pin for the chip-select | GPMC_CONFIG1_i[17:16] WAITPINSELECT | x |

Table 15-248. Enable Chip-Select

| Sub-process Name | Register / Bit Field | Value |
|------------------------------------------------------------|---------------------------|-------|
| When all parameters are configured, enable the chip-select | GPMC_CONFIG7_i[6] CSVALID | x |

15.4.5.4 GPMC Configuration in NAND Mode

This section gives a generic configuration for parameters related to the NAND memory connected to the GPMC.

Table 15-249. NAND Memory Type

| Sub-process Name | Register / Bit Field | Value |
|------------------------------------------------------------------------------------------------------|---------------------------------------------------------|-------|
| Set the NAND protocol | GPMC_CONFIG1_i[11:10] DEVICETYPE | 0x2 |
| Set a device size | GPMC_CONFIG1_i[13:12] DEVICESIZE | x |
| Set the address and data multiplexing protocol to non-multiplexed attached device | GPMC_CONFIG1_i[9] MUXADDDATA | 0x0 |
| Select a timing signals latencies factor | GPMC_CONFIG1_i[4] TIMEPARAGRANULARITY | x |
| Set a synchronous or asynchronous mode and a single or multiple access for read and write operations | See Section 15.4.5.5, Set Memory Access | x |

Table 15-250. NAND Chip-Select Configuration

| Sub-process Name | Register / Bit Field | Value |
|--------------------------------------------------------|----------------------------------|-------|
| Select the chip-select base address | GPMC_CONFIG7_i[5:0] BASEADDRESS | x |
| Select the chip-select minimum granularity (16M bytes) | GPMC_CONFIG7_i[11:8] MASKADDRESS | x |

Table 15-251. Asynchronous Read and Write Operations

| Sub-process Name | Register / Bit Field | Value |
|------------------------------------------------------------|----------------------------------------------------------------------|-------|
| Configure adequate timing parameters in asynchronous modes | See Section 15.4.5.6 , <i>GPMC Timing Parameters</i> | |

Table 15-252. ECC Engine

| Sub-process Name | Register / Bit Field | Value |
|-------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|---------------------|
| Select the ECC result register where the first ECC computation is stored (Only applies to Hamming) | GPMC_ECC_CONTROL[3:0] ECCPOINTER | x ⁽¹⁾ |
| Clear all ECC result registers | GPMC_ECC_CONTROL[8] ECCCLEAR | Write '1' to clear. |
| Define ECCSIZE0 and ECCSIZE1 | GPMC_ECC_SIZE_CONFIG[19:12] ECCSIZE0 and [29:22] ECCSIZE1 | x ⁽²⁾ |
| Select the size of each of the 9 result registers (size specified by ECCSIZE0 or ECCSIZE1) | GPMC_ECC_SIZE_CONFIG[j-1] ECCjRESULTSIZE where j = 1 to 9 | x |
| Select the chip-select where ECC is computed | GPMC_ECC_CONFIG[3:1] ECCCS | x |
| Select the Hamming code or BCH code ECC algorithm in use | GPMC_ECC_CONFIG[16] ECCALGORITHM | x |
| Select word size for ECC calculation | GPMC_ECC_CONFIG[7] ECC16B | x |
| If the BCH code is used, Set an error correction capability and Select a number of sectors to process | GPMC_ECC_CONFIG[13:12] ECCBCHTSEL and GPMC_ECC_CONFIG[6:4] ECCTOPSECTOR | x |
| Enable the ECC computation | GPMC_ECC_CONFIG[0] ECCENABLE | 0x1 |

⁽¹⁾ This parameter depends on the numbers of sectors in a page.

⁽²⁾ Depends on the size of each sector in the NAND page.

Table 15-253. Prefetch and Write-Posting Engine

| Sub-process Name | Register / Bit Field | Value |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------|-------|
| Disable the engine before configuration | GPMC_PREFETCH_CONTROL[0] STARTENGINE | 0x0 |
| Select the chip-select associated with a NAND device where the prefetch engine is active | GPMC_PREFETCH_CONFIG1[26:24] ENGINECSSELECTOR | x |
| Select access direction through prefetch engine, read or write. | GPMC_PREFETCH_CONFIG1[0] ACCESSMODE | x |
| Select the threshold used to issue a DMA request | GPMC_PREFETCH_CONFIG1[14:8] FIFOTHRESHOLD | x |
| Select either DMA synchronized mode or software manual mode. | GPMC_PREFETCH_CONFIG1[2] DMAMODE | x |
| Select if the engine immediately starts accessing the memory upon STARTENGINE assertion or if hardware synchronization based on a WAIT signal is used. | GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE | x |
| Select which wait pin edge detector should start the engine in synchronized mode | GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR | x |
| Enter a number of clock cycles removed to timing parameters (For all back-to-back accesses to the NAND flash but not the first one) | GPMC_PREFETCH_CONFIG1[30:28] CYCLOPTIMIZATION | x |
| Enable the prefetch postwrite engine | GPMC_PREFETCH_CONFIG1[7] ENABLEENGINE | 0x1 |
| Select the number of bytes to be read or written by the engine to the selected chip-select | GPMC_PREFETCH_CONFIG2[13:0] TRANSFERCOUNT | x |
| Start the prefetch engine | GPMC_PREFETCH_CONTROL[0] STARTENGINE | 0x1 |

Table 15-254. Wait Pin Configuration

| Sub-process Name | Register / Bit Field | Value |
|----------------------------------------------------------------------------------|-----------------------------------------------|-------|
| Selects when the engine starts the access to CS | GPMC_PREFETCH_CONFIG1[3] SYNCHROMODE | x |
| Select which wait pin edge detector should start the engine in synchronized mode | GPMC_PREFETCH_CONFIG1[5:4] WAITPINSELECTOR | x |

Table 15-255. Enable Chip-Select

| Sub-process Name | Register / Bit Field | Value |
|------------------------------------------------------------|--------------------------|-------|
| When all parameters are configured, enable the chip-select | GPMC_CONFIG7_[6] CSVALID | x |

15.4.5.5 Set Memory Access

This section details the bit field to configure to set the GPMC in various memory modes.

Table 15-256. Mode Parameters Check List Table

| Register | Bit | Bit field name | Asynchronous | | | | Synchronous | | | |
|----------------|-----|----------------|--------------------|---------------------|-----------------------------|------------------------------|--------------------|---------------------|------------------------------|-------------------------------|
| | | | Single Read Access | Single Write Access | Multiple Read (Page) Access | Multiple Write (Page) Access | Single Read Access | Single Write Access | Multiple Read (Burst) Access | Multiple Write (Burst) Access |
| GPMC_CONFIG1_i | 30 | READMULTIPLE | 0x0 | - | 0x1 ⁽¹⁾ | N/S | 0x0 | - | 0x1 | - |
| GPMC_CONFIG1_i | 29 | READTYPE | 0x0 | - | 0x0 ⁽¹⁾ | N/S | 0x1 | - | 0x1 | - |
| GPMC_CONFIG1_i | 28 | WRITEMULTIPLE | - | 0x0 | - ⁽¹⁾ | N/S | - | 0x0 | - | 0x1 |
| GPMC_CONFIG1_i | 27 | WRITETYPE | - | 0x0 | - ⁽¹⁾ | N/S | - | 0x1 | - | 0x1 |

⁽¹⁾ Multiple read is not supported in address/data- and AAD-multiplexed modes. Multiple read is supported in Nonmultiplexed mode.

Table 15-257. Access Type Parameters Check List Table

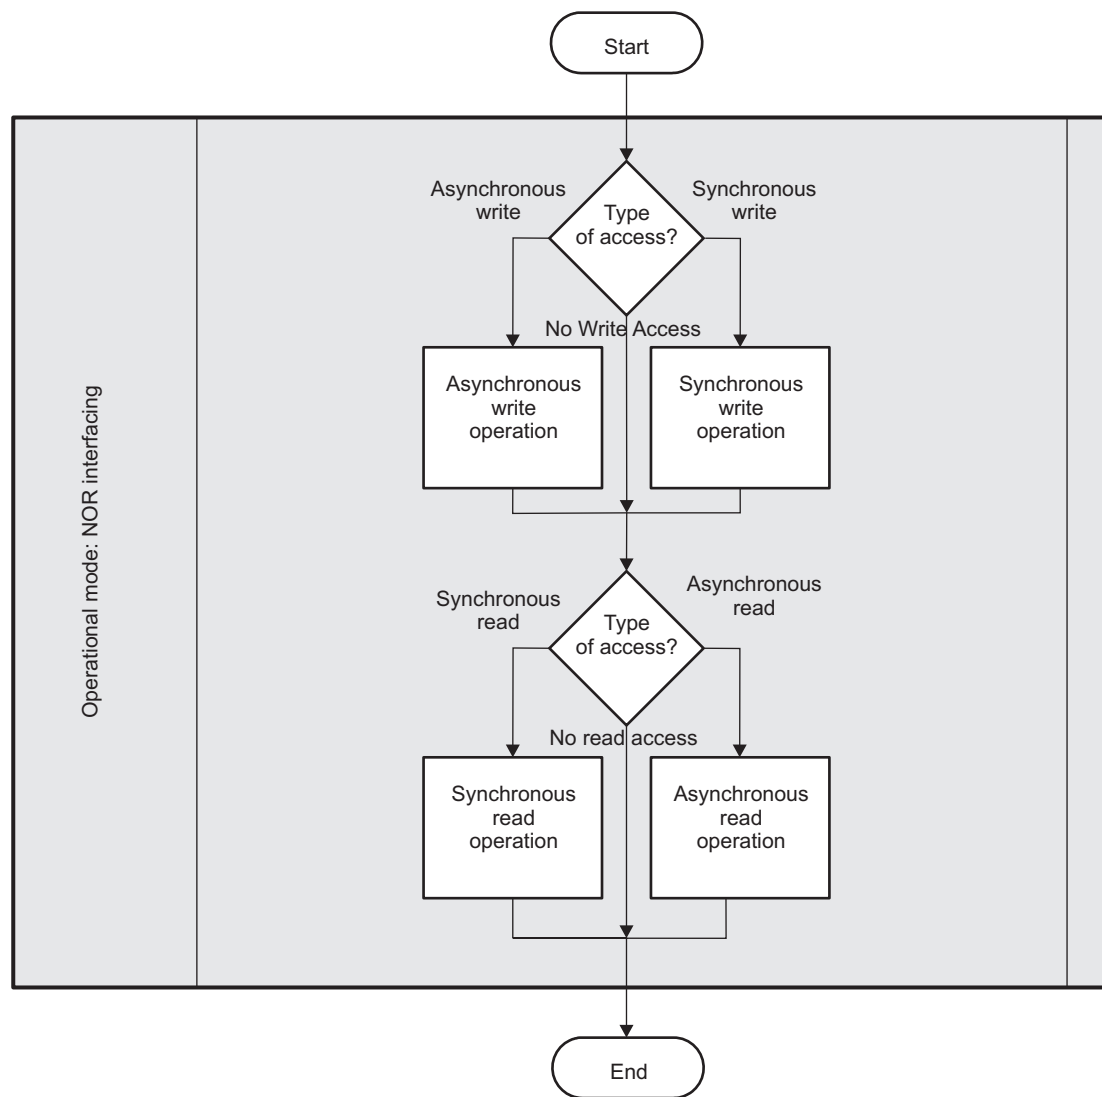

| Register | Bit | Bit field name | Access Type | | |
|----------------|-----|-------------------------------|-------------|-------------------|---------|
| | | | Non-mux | Address /Data Mux | AAD-mux |
| GPMC_CONFIG1_i | 9:8 | MUXADDDATA | 0x0 | 0x2 | 0x1 |
| GPMC_CONFIG | 1 | LIMITEDADDRESS ⁽¹⁾ | 0x1 | 0x0 | 0x0 |

⁽¹⁾ This parameter applies to all chip-selects. There is no per-CS configuration for this parameter.

15.4.5.6 GPMC Timing Parameters

Figure 15-92 shows a programming model diagram for the NOR interfacing timing parameters.

Figure 15-92. NOR Interfacing Timing Parameters Diagram

gpmc-uc-002

Table 15-258 lists bit fields to configure adequate timing parameter in various memory modes.

Table 15-258. Timing Parameters

| Register | Bit | Bit field name | Asynchronous | | | Synchronous | | | | Access Type | | |
|----------------|-------|---------------------|--------------------|---------------------|-----------------------------|--------------------|---------------------|------------------------------|-------------------------------|-----------------|--------------------------|-----------------|
| | | | Single Read Access | Single Write Access | Multiple Read (Page) access | Single Read Access | Single Write Access | Multiple Read (Burst) Access | Multiple Write (Burst) Access | Non-multiplexed | Address/Data-multiplexed | AAD-multiplexed |
| GPMC_CONFIG1_i | 9 | MUXADDDATA | y | y | y | y | y | y | y | y | y | y |

15.4.5.6.1 GPMC Timing Parameters Formulas

This section intends to help the user to calculate the GPMC timing bit fields values. Formulas are not listed exhaustively.

The section details:

- NAND Flash Interface Timing Parameters Formulas
- Synchronous NOR Flash Timing Parameters Formulas
- Asynchronous NOR Flash Timing Parameters Formulas

15.4.5.6.1.1 NAND Flash Interface Timing Parameters Formulas

This section lists formulas to use in order to calculate NAND timing parameters. This is the case when [GPMC_CONFIG1_j\[11:10\] DEVICETYPE = 0x2](#). [Table 15-259](#) details NAND timing parameters.

Table 15-259. NAND Formulas Description Table

| Configuration Parameter | Unit | Description |
|-------------------------|------|----------------------------------------------------------------------|
| A | ns | Pulse duration - gpmc_nwe valid time |
| B | ns | Delay time - gpmc_ncs valid to gpmc_nwe valid |
| C | ns | Delay time - gpmc_nbe0_cle/gpmc_nadv_ale high to gpmc_nwe valid |
| D | ns | Delay time - gpmc_ad[15:0] valid to gpmc_nwe valid |
| E | ns | Delay time - gpmc_nwe invalid to gpmc_ad[15:0] invalid |
| F | ns | Delay time - gpmc_nwe invalid to gpmc_nbe0_cle/gpmc_nadv_ale invalid |
| G | ns | Delay time - gpmc_nwe invalid to gpmc_ncs invalid |
| H | ns | Cycle time - Write cycle time |
| I | ns | Delay time - gpmc_ncs valid to gpmc_noe valid |
| J | ns | Setup time - gpmc_ad[15:0] valid to gpmc_noe invalid |
| K | ns | Pulse duration - gpmc_noe valid time |
| L | ns | Cycle time - Read cycle time |
| M | ns | Delay time - gpmc_noe invalid to gpmc_ncs invalid |

The configuration parameters are calculated through the following formulas.

$$A = (WEOffTime - WEOnTime) * (TimeParaGranularity + 1) * GPMC_FCLK \text{ period}$$

$$B = ((WEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - CSEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$C = ((WEOnTime - ADVOnTime) * (TimeParaGranularity + 1) + 0.5 * (WEEExtraDelay - ADVExtraDelay)) * GPMC_FCLK \text{ period}$$

$$D = (WEOnTime * (TimeParaGranularity + 1) + 0.5 * WEEExtraDelay) * GPMC_FCLK \text{ period}$$

$$E = (WrCycleTime - WEOffTime * (TimeParaGranularity + 1) - 0.5 * WEEExtraDelay) * GPMC_FCLK \text{ period}$$

$$F = (ADVWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (ADVExtraDelay - WEEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$G = (CSWrOffTime - WEOffTime * (TimeParaGranularity + 1) + 0.5 * (CSEExtraDelay - WEEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$H = WrCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$$

$$I = ((OEOnTime - CSOnTime) * (TimeParaGranularity + 1) + 0.5 * (OEEExtraDelay - CSEExtraDelay)) * GPMC_FCLK \text{ period}$$

$$J = ((AccessTime - OEOffTime) * (TimeParaGranularity + 1) - 0.5 * OEEExtraDelay) * GPMC_FCLK \text{ period}$$

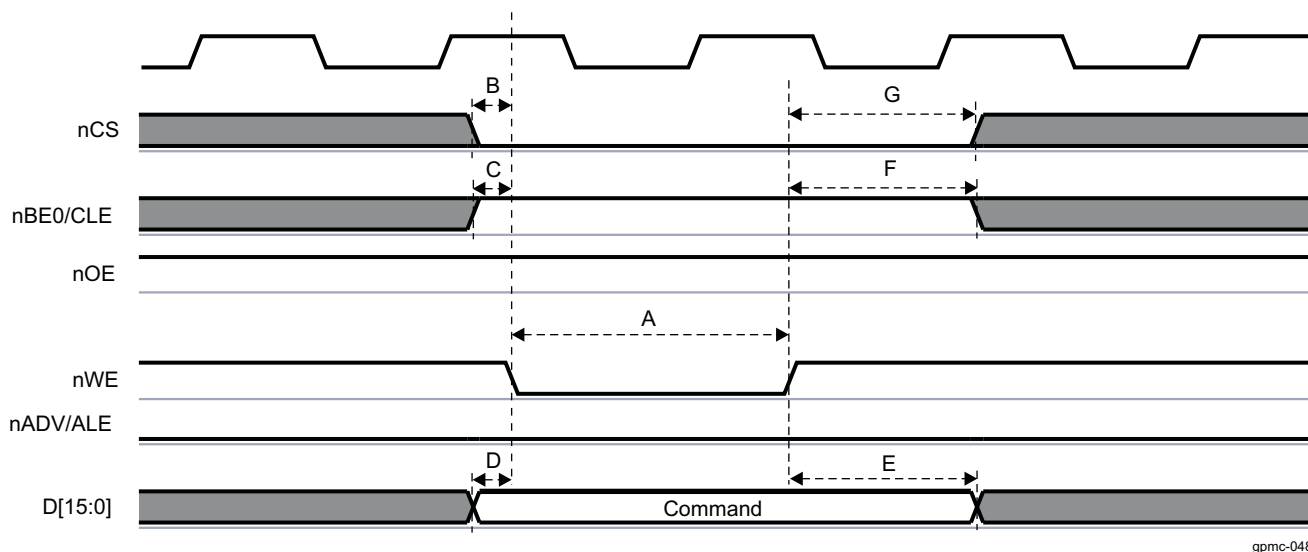

$$K = (OEOffTime - OEOnTime) * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$$

$$L = RdCycleTime * (1 + TimeParaGranularity) * GPMC_FCLK \text{ period}$$

$$M = (\text{CSRdOffTime} - \text{OEOffTime} * (\text{TimeParaGranularity} + 1) + 0.5 * (\text{CSExtraDelay} - \text{OEEExtraDelay}) * \text{GPMC_FCLK period}$$

Figure 15-93 shows a command latch cycle timing simplified example where formulas are associated with signal waves.

Figure 15-93. NAND Command Latch Cycle Timing Simplified Example

15.4.5.6.1.2 Synchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate synchronous NOR timing parameters. This is the case when `GPMC_CONFIG1_[11:10] DEVICETYPE = 0x0` and when `READTYPE` or `WRITETYPE` are set to synchronous mode.

Table 15-260. Synchronous NOR Formulas Description Table

| Configuration Parameter | Unit | Description |
|-------------------------|------|---------------------------------------------------------------------------------------------------------------------------------------------|
| A | ns | Pulse duration - gpmc_ncs low |
| B | ns | Delay time - address bus valid to gpmc_clk first edge Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_clk first edge |
| C | ns | Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 low |
| D | ns | Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 invalid Delay time - gpmc_clk rising edge to gpmc_nadv_ale invalid |
| E | ns | Delay time - gpmc_clk rising edge to gpmc_ncs invalid Delay time - gpmc_clk rising edge to gpmc_noe invalid |
| F | ns | Delay time - gpmc_clk rising edge to gpmc_ncs transition |
| G | ns | Delay time - gpmc_clk rising edge to gpmc_nadv_ale transition |
| H | ns | Delay time - gpmc_clk rising edge to gpmc_noe transition |
| I | ns | Delay time - gpmc_clk rising edge to gpmc_nwe transition |
| J | ns | Delay time - gpmc_clk rising edge to gpmc_ad data bus transition Delay time - gpmc_clk rising edge to gpmc_nbe0_cle/gpmc_nbe1 transition |
| K | ns | Pulse duration - gpmc_nadv_ale low |
| L | ns | Delay time - gpmc_wait invalid to first data latching gpmc_clk edge |

The configuration parameters are calculated through the following formulas.

1. For single read accesses:

$$A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$C = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$D = (\text{RDCYCLETIME} - \text{ACCESSTIME}) * \text{GPMC_FCLK period}$$

$$E = (\text{CSRDOFFTIME} - \text{ACCESSTIME}) * \text{GPMC_FCLK period}$$

2. For burst read accesses (where n is the page burst access number):

$$A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$C = (\text{RDCYCLETIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$D = (\text{RDCYCLETIME} - (\text{ACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$$

$$E = (\text{CSRDOFFTIME} - (\text{ACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$$

3. For burst write accesses (where n is the page burst access number):

$$A = (\text{CSWROFFTIME} - \text{CSONTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$C = (\text{WRCYCLETIME} + (n - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$$

$$D = (\text{WRCYCLETIME} - (\text{ACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$$

$$E = (\text{CSWROFFTIME} - (\text{ACCESSTIME} + (n - 1) * \text{PAGEBURSTACCESSTIME})) * \text{GPMC_FCLK period}$$

4. For all accesses:

For nCS falling edge (CS activated):

- Case where [GPMC_CONFIG1_j\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:

$$F = 0.5 * \text{CSEXTRADelay} * \text{GPMC_FCLK period}$$

- Case where GPMCFCLKDIVIDER = 0x1:

F = 0.5 * CSEXTRADelay * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSONTIME are odd) or (CLKACTIVATIONTIME and CSONTIME are even)

F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:

F = 0.5 * CSEXTRADelay * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME) is a multiple of 3

F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

F = (2 + 0.5 * CSEXTRADelay) * GPMC_FCLK period, when (CSONTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nCS rising edge (CS deactivated) in reading mode:

- Case where [GPMC_CONFIG1_j\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:

$$F = 0.5 * \text{CSEXTRADelay} * \text{GPMC_FCLK period}$$

- Case where GPMCFCLKDIVIDER = 0x1:

F = 0.5 * CSEXTRADelay * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSRDOFFTIME are odd) or (CLKACTIVATIONTIME and CSRDOFFTIME are even)

F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK period otherwise.

- Case where GPMCFCLKDIVIDER = 0x2:

F = 0.5 * CSEXTRADelay * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME) is a multiple of 3

F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 1) is a multiple of 3

F = (2 + 0.5 * CSEXTRADelay) * GPMC_FCLK period, when (CSRDOFFTIME - CLKACTIVATIONTIME - 2) is a multiple of 3

For nCS rising edge (CS deactivated) in writing mode:

- Case where [GPMC_CONFIG1_j\[1:0\]](#) GPMCFCLKDIVIDER = 0x0:

$$F = 0.5 * \text{CSEXTRADelay} * \text{GPMC_FCLK period}$$

- Case where GPMCFCLKDIVIDER = 0x1:

F = 0.5 * CSEXTRADelay * GPMC_FCLK period, when (CLKACTIVATIONTIME and CSWROFFTIME are odd) or (CLKACTIVATIONTIME and CSWROFFTIME are even)

F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK period otherwise.

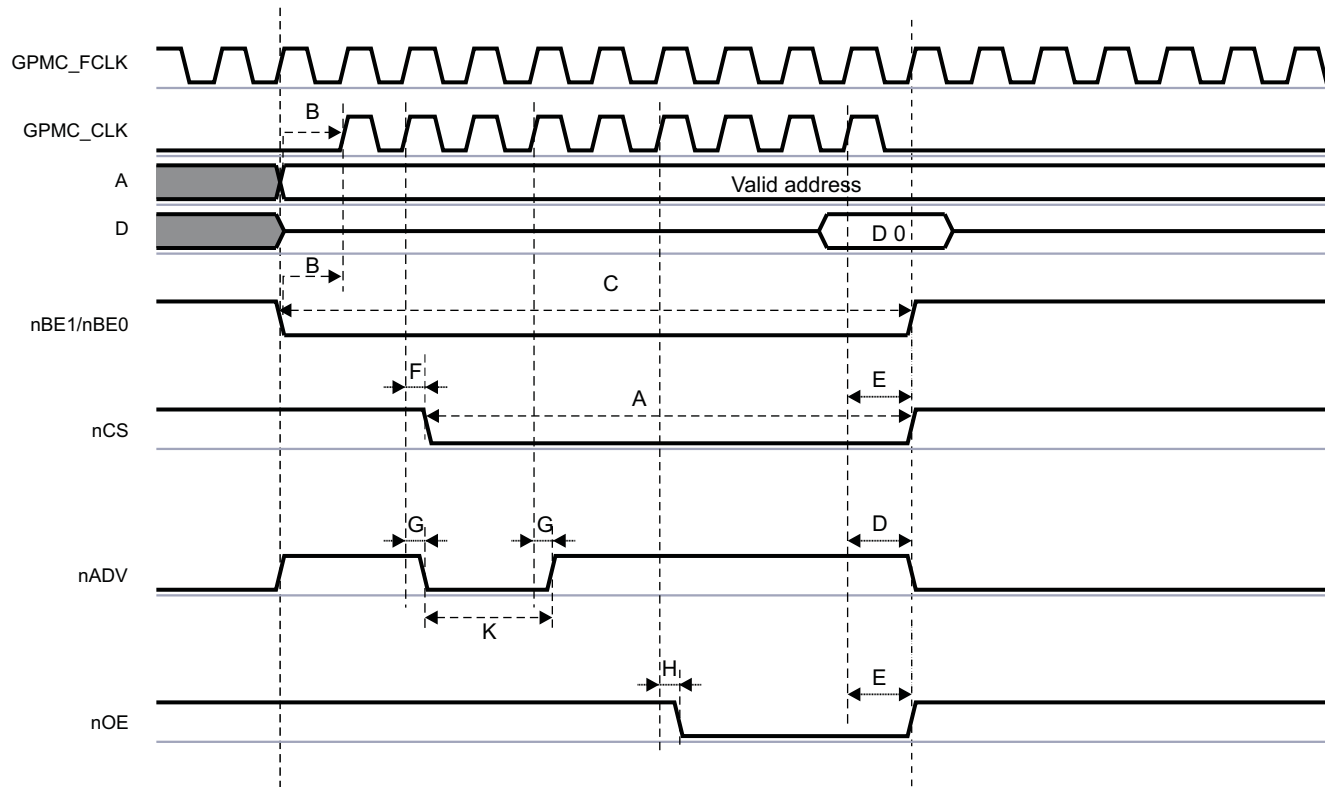

- Case where GPMCFCLKDIVIDER = 0x2:
 $F = 0.5 * CSEXTRADelay * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $F = (1 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $F = (2 + 0.5 * CSEXTRADelay) * GPMC_FCLK \text{ period, when } (CSWROFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
- For nADV falling edge (nADV activated):
- Case where GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVONTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVONTIME \text{ are even})$
 $G = (1 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $G = (1 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $G = (2 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period, when } (ADVONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
- For nADV rising edge (nADV deactivated) in reading mode:
- Case where GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVRDOFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVRDOFFTIME \text{ are even})$
 $G = (1 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period, when } (ADVRDOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $G = (1 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period, when } (ADVRDOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $G = (2 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period, when } (ADVRDOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
- For nADV rising edge (nADV deactivated) in writing mode:
- Case where GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } ADVWROFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } ADVWROFFTIME \text{ are even})$
 $G = (1 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:
 $G = 0.5 * ADVEXTRADelay * GPMC_FCLK \text{ period, when } (ADVWROFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $G = (1 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period, when } (ADVWROFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $G = (2 + 0.5 * ADVEXTRADelay) * GPMC_FCLK \text{ period, when } (ADVWROFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
- For nOE falling edge (nOE activated):
- Case where GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0:
 $H = 0.5 * OEEXTRADelay * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $H = 0.5 * OEEXTRADelay * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } OEONTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } OEONTIME \text{ are even})$
 $H = (1 + 0.5 * OEEXTRADelay) * GPMC_FCLK \text{ period otherwise.}$

- Case where GPMCFCLKDIVIDER = 0x2:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period, when } (OEONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
- For nOE rising edge (nOE deactivated):
- Case where GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } OEOFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } OEOFFTIME \text{ are even})$
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:
 $H = 0.5 * OEEXTRADELAY * GPMC_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $H = (1 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $H = (2 + 0.5 * OEEXTRADELAY) * GPMC_FCLK \text{ period, when } (OEOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
- For nWE falling edge (nWE activated):
- Case where GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } WEONTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } WEONTIME \text{ are even})$
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK \text{ period, when } (WEONTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
- For nWE rising edge (nWE deactivated):
- Case where GPMC_CONFIG1_j[1:0] GPMCFCLKDIVIDER = 0x0:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period}$
- Case where GPMCFCLKDIVIDER = 0x1:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period, when } (CLKACTIVATIONTIME \text{ and } WEOFFTIME \text{ are odd}) \text{ or } (CLKACTIVATIONTIME \text{ and } WEOFFTIME \text{ are even})$
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK \text{ period otherwise.}$
- Case where GPMCFCLKDIVIDER = 0x2:
 $I = 0.5 * WEEXTRADELAY * GPMC_FCLK \text{ period, when } (WEOFFTIME - CLKACTIVATIONTIME) \text{ is a multiple of } 3$
 $I = (1 + 0.5 * WEEXTRADELAY) * GPMC_FCLK \text{ period, when } (WEOFFTIME - CLKACTIVATIONTIME - 1) \text{ is a multiple of } 3$
 $I = (2 + 0.5 * WEEXTRADELAY) * GPMC_FCLK \text{ period, when } (WEOFFTIME - CLKACTIVATIONTIME - 2) \text{ is a multiple of } 3$
- For gpmc_nadv low pulse duration:
- Read operation:
 $K = (ADVRDOFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
- Write operation:
 $K = (ADVWROFFTIME - ADVONTIME) * (TIMEPARAGRANULARITY + 1) * GPMC_FCLK \text{ period}$
- For gpmc_wait invalid to first data latching gpmc_clk edge:
- $L = WAITMONITORINGTIME * (GPMCFCLKDIVIDER + 1) * GPMC_FCLK \text{ period} + GPMC_CLK$

period

Figure 15-94 shows a synchronous NOR single read simplified example where formulas are associated with signal waves.

Figure 15-94. Synchronous NOR Single Read Simplified Example

gpmc-046

15.4.5.6.1.3 Asynchronous NOR Flash Timing Parameters Formulas

This section lists all formulas to use in order to calculate asynchronous NOR timing parameters. This is the case when `GPMC_CONFIG1_i[11:10] DEVICETYPE = 0x0` and when `READTYPE` or `WRITETYPE` are set to asynchronous mode.

Table 15-261. Asynchronous NOR Formulas Description Table

| Configuration Parameter | Unit | Description |
|-------------------------|------|----------------------------------------------------------------|
| A | ns | Pulse duration - gpmc_ncs low |
| B | ns | Delay time - gpmc_ncs valid to gpmc_nadv_ale invalid |
| C | ns | Delay time - gpmc_ncs valid to gpmc_noe invalid (single read) |
| D | ns | Pulse duration - address bus valid - 2nd, 3rd and 4th accesses |
| E | ns | Delay time - gpmc_ncs valid to gpmc_nwe valid |
| F | ns | Delay time - gpmc_ncs valid to gpmc_nwe invalid |
| G | ns | Address invalid duration between 2 successive R/W accesses |
| H | ns | Setup time - read data valid before gpmc_noe high |
| I | ns | Delay time - gpmc_ncs valid to gpmc_noe invalid (burst read) |
| J | ns | Delay time - address bus valid to gpmc_ncs valid |
| | | Delay time - data bus valid to gpmc_ncs valid |
| | | Delay time - gpmc_nbe0_cle/gpmc_nbe1 valid to gpmc_ncs valid |
| K | ns | Delay time - gpmc_ncs valid to gpmc_nadv_ale valid |

Table 15-261. Asynchronous NOR Formulas Description Table (continued)

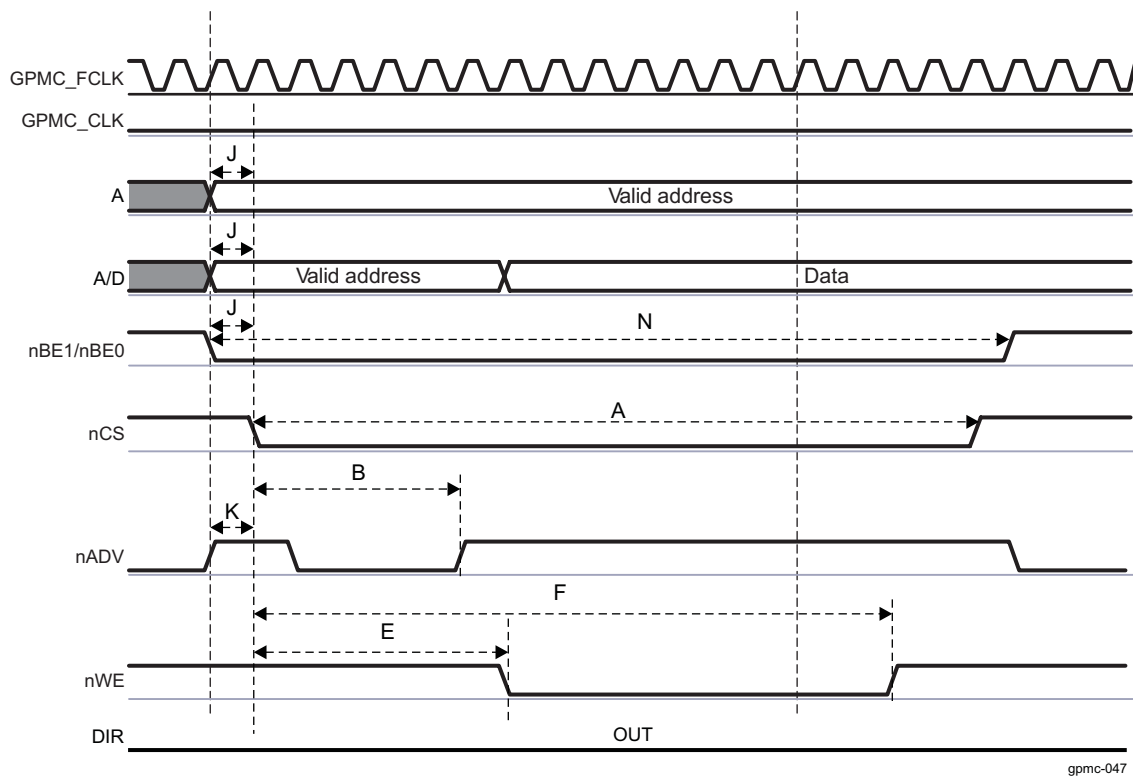

| Configuration Parameter | Unit | Description |
|-------------------------|------|---------------------------------------------------------|
| L | ns | Delay time - gpmc_ncs valid to gpmc_noe valid |
| M | ns | Delay time - gpmc_ncs valid to first data latching edge |
| N | ns | Pulse duration - gpmc_nbe0_cle/gpmc_nbe1 valid time |
| O | ns | Delay time - gpmc_ncs valid to gpmc_nadv_ale valid |

The configuration parameters are calculated through the following formulas. Note that these formulas are not exhaustive.

- gpmc_ncs low pulse:
For single read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst read: $A = (\text{CSRDOFFTIME} - \text{CSONTIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
For single write: $A = (\text{CSWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst write: $A = (\text{CSWROFFTIME} - \text{CSONTIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
- gpmc_ncs valid to gpmc_nadv_ale invalid delay:
For reading: $B = ((\text{ADVRDOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
For writing: $B = ((\text{ADVWROFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $C = ((\text{OEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $D = \text{PAGEBURSTACCESSTIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
- $E = ((\text{WEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $F = ((\text{WEOFFTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{WEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $G = \text{CYCLE2CYCLEDELAY} * \text{GPMC_FCLK period}$
- $H = ((\text{OEOFFTIME} - \text{ACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{OEEXTRADELAY}) * \text{GPMC_FCLK period}$
- $I = ((\text{OEOFFTIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$, where N = page burst access number
- $J = (\text{CSONTIME} * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$
- $K = ((\text{ADVONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $L = ((\text{OEONTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{OEEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$
- $M = ((\text{ACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) - 0.5 * \text{CSEXTRADELAY}) * \text{GPMC_FCLK period}$
- gpmc_nbe0_cle/gpmc_nbe1 pulse:
For single read: $N = \text{RDCYCLETIME} * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$
For burst read: $N = (\text{RDCYCLETIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
For burst write: $N = (\text{WRCYCLETIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME}) * (\text{TIMEPARAGRANULARITY} + 1) * \text{GPMC_FCLK period}$, where N = page burst access number
- $O = ((\text{WRCYCLETIME} + (\text{N} - 1) * \text{PAGEBURSTACCESSTIME} - \text{CSONTIME}) * (\text{TIMEPARAGRANULARITY} + 1) + 0.5 * (\text{ADVEXTRADELAY} - \text{CSEXTRADELAY})) * \text{GPMC_FCLK period}$

Figure 15-95 shows an asynchronous NOR single write simplified example where formulas are associated with signal waves.

Figure 15-95. Asynchronous NOR Single Write Simplified Example

NOTE: Write multiple access is not supported in asynchronous mode. If WRITEMULTIPLE is enabled with WRITETYPE as asynchronous, the GPMC processes single asynchronous accesses.

15.4.6 GPMC Use Cases And Tips

15.4.6.1 How to Set GPMC Timing Parameters for Typical Accesses

15.4.6.1.1 External Memory Attached to the GPMC Module

As discussed in the introduction to this chapter, the GPMC module supports the following external memory types:

- Asynchronous or synchronous, 8-bit or 16-bit-width memory or device
- 16-bit address/data-multiplexed or not multiplexed NOR flash device
- 8- or 16-bit NAND flash device

The following examples show how to calculate GPMC timing parameters by showing a typical parameter setup for the access to be performed.

The example is based on a 512-Mb multiplexed NOR flash memory with the following characteristics:

- Type: NOR flash (address/data-multiplexed mode)
- Size: 512M bits
- Data Bus: 16 bits wide
- Speed: 104 MHz clock frequency
- Read access time: 80 ns

15.4.6.1.2 Typical GPMC Setup

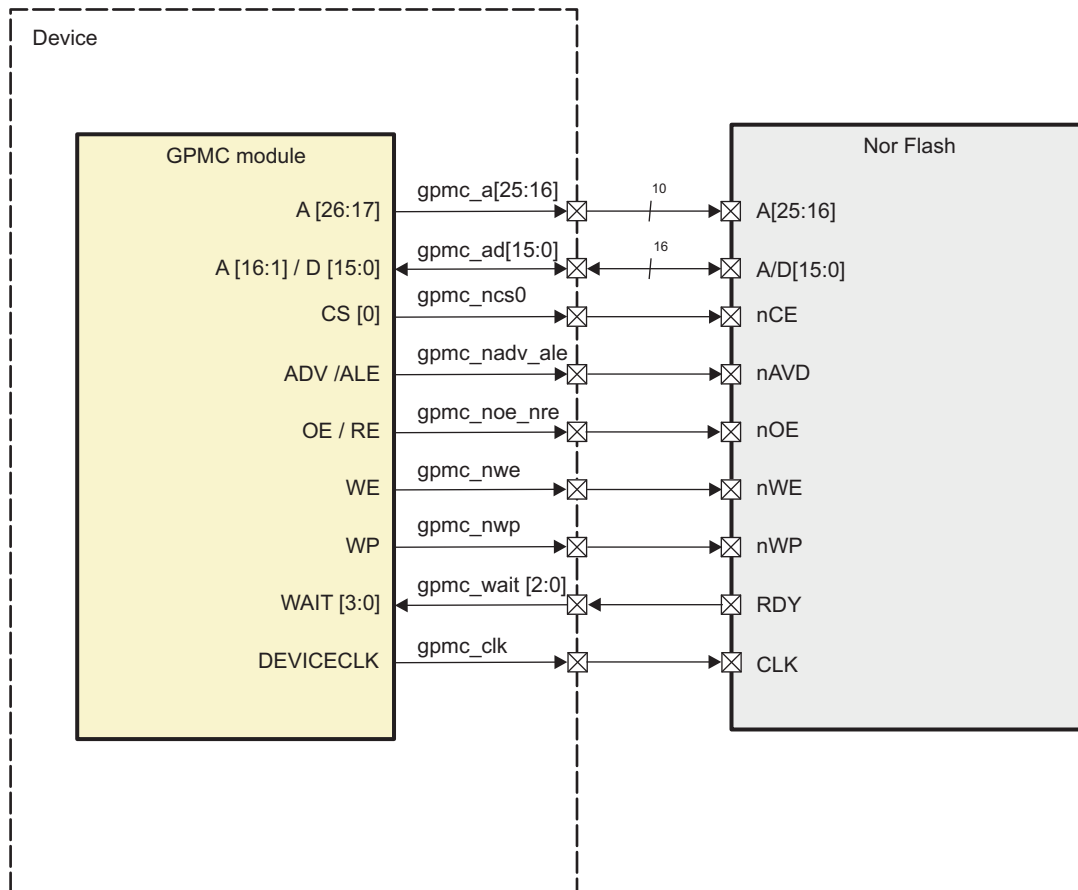

Table 15-262 lists some of the I/Os of the GPMC module.

Table 15-262. GPMC Signals

| Signal Name | I/O | Description |
|----------------|----------|--------------------------------------------------------------------------------------|
| GPMC_FCLK | Internal | Functional and interface clock. Acts as the time reference. |
| gpmc_clk | O | External clock provided to the external device for synchronous operations |
| gpmc_a[25:16] | O | Address |
| gpmc_ad[15: 0] | I/O | Data-multiplexed with addresses A[16:1] on memory side |
| gpmc_ncsx | O | Chip-select (where x = 0, or 1) |
| gpmc_nadv_ale | O | Address valid enable |
| gpmc_noe_nre | O | Output enable (read access only) |
| gpmc_nwe | O | Write enable (write access only) |
| gpmc_wait[2:0] | I | Ready signal from memory device. Indicates when valid burst data is ready to be read |

Figure 15-96 shows the typical connection between the GPMC module and an attached NOR Flash memory.

Figure 15-96. GPMC Connection to an External NOR Flash Memory

gpmc-037

The following sections demonstrate how to calculate GPMC parameters for three access types:

- Synchronous burst read
- Asynchronous read
- Asynchronous single write

15.4.6.1.2.1 GPMC Configuration for Synchronous Burst Read Access

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9,615 \text{ ns}$).

Table 15-263 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Table 15-264 shows how to calculate timings for the GPMC using the memory parameters.

Figure 15-97 shows the synchronous burst read access.

Table 15-263. Useful Timing Parameters on the Memory Side

| AC Read Characteristics on the Memory Side | Description | Duration (ns) |
|--------------------------------------------|-----------------------------|---------------|
| tCES | nCS setup time to clock | 0 |
| tACS | Address setup time to clock | 3 |
| tIACC | Synchronous access time | 80 |

Table 15-263. Useful Timing Parameters on the Memory Side (continued)

| AC Read Characteristics on the Memory Side | Description | Duration (ns) |
|--------------------------------------------|-----------------------------------------------|---------------|
| tBACC | Burst access time valid clock to output delay | 5,2 |
| tCEZ | Chip-select to High-Z | 7 |
| tOEZ | Output enable to High-Z | 7 |
| tAVC | nADV setup time | 6 |
| tAVD | nAVD pulse | 6 |
| tACH | Address hold time from clock | 3 |

The following terms, which describe the timing interface between the controller and its attached device, are used to calculate the timing parameters on the GPMC side:

- Read Access time (GPMC side): Time required to activate the clock + read access time requested on the memory side + data setup time required for optimal capture of a burst of data
- Data setup time (GPMC side): Ensures a good capture of a burst of data (as opposed to taking a burst of data out). One word of data is processed in one clock cycle ($T = 9,615$ ns). The read access time between 2 bursts of data is $tBACC = 5,2$ ns. Therefore, data setup time is a clock period - $tBACC = 4,415$ ns of data setup.
- Access completion (GPMC side): (Different from page burst access time) Time required between the last burst access and access completion: nCS/nOE hold time (nCS and nOE must be released at the end of an access. These signals are held to allow the access to complete).
- Read cycle time (GPMC side): Read Access time + access completion
- Write cycle time for burst access: Not supported for NOR flash memory

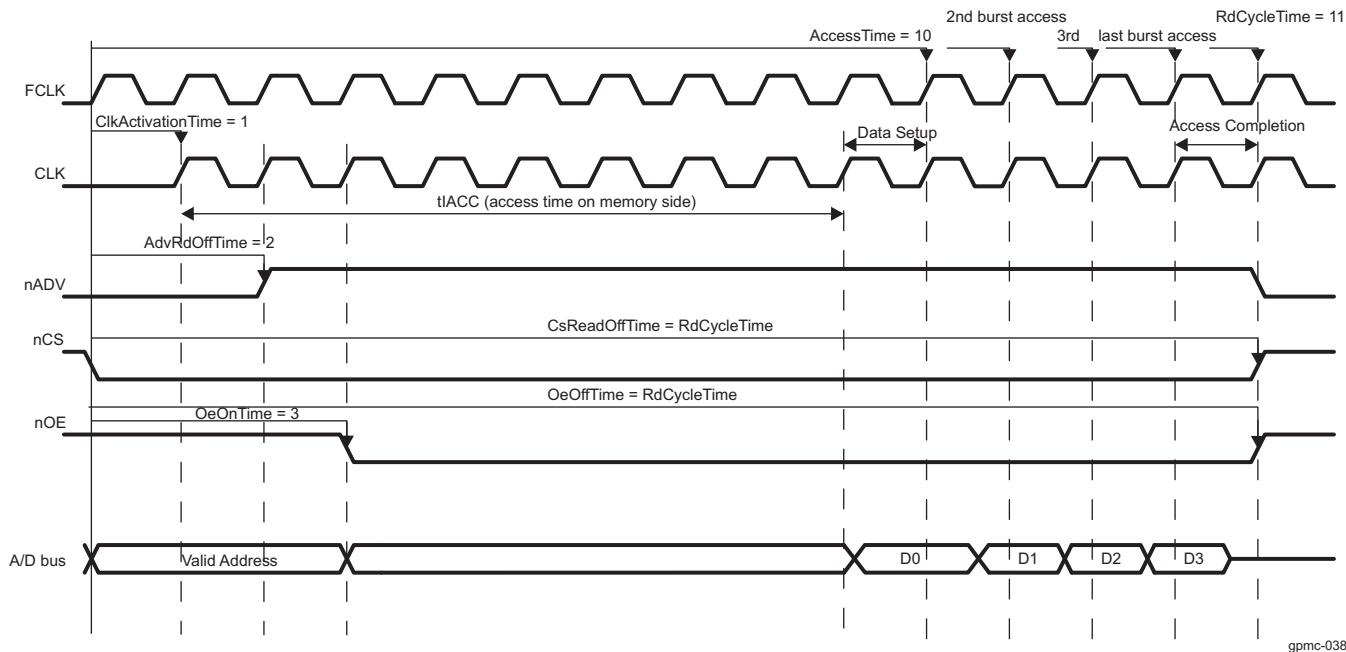

Table 15-264. Calculating GPMC Timing Parameters

| Parameter Name on GPMC Side | Formula | Duration (ns) | Number of Clock Cycles (F = 104 MHz) | GPMC Register Configurations |
|-----------------------------|----------------------------------------------------------------------------------------------|-----------------------------|------------------------------------------|------------------------------|
| GPMC FCLK Divider | - | - | - | GPMCFCLKDIVIDER = 0x0 |
| ClkActivation Time | $\min (tCES, tACS)$ | 3 | 1 | CLKACTIVATIONTIME = 0x1 |
| RdAccessTime | $\text{roundmax} (\text{ClkActivationTime} + tIACC + \text{DataSetupTime})$ | 94,03: (9,615 + 80 + 4,415) | 10 : $\text{roundmax} (94,03 / 9,615)$ | ACCESSTIME = 0x0A |
| PageBurst AccessTime | $\text{roundmax} (tBACC)$ | $\text{roundmax} (5,2)$ | 1 | PAGEBURSTACCESSTIME = 0x1 |
| RdCycleTime | $\text{AccessTime} + \max (tCEZ, tOEZ)$ | 101, 03: (94, 03 + 7) | 11 | RDCYCLETIME = 0x0B |
| CsOnTime | tCES | 0 | 0 | CSONTIME = 0x0 |
| CsReadOffTime | RdCycleTime | - | 11 | CSRDOFFTIME = 0x0B |
| AdvOnTime | tAVC ⁽¹⁾ | 0 | 0 | ADVONTIME = 0x0 |
| AdvRdOffTime | tAVD + tAVC ⁽²⁾ | 12 | 2 | ADVRDOFFTIME = 0x02 |
| OeOnTime ⁽³⁾ | $(\text{ClkActivationTime} + tACH) < \text{OeOnTime} (\text{ClkActivationTime} + tIACC)$ | - | 3 for instance. | OEONTIME = 0x3 |
| OeOffTime | RdCycleTime | - | 11 | OEOFFTIME = 0x0B |

⁽¹⁾ The external clock provided to the NOR flash is not yet available.

⁽²⁾ $\text{AdvRdOffTime} - \text{AdvOnTime} = tAVD$; thus, $\text{AdvRdOffTime} = tAVD + \text{AdvOnTime} = tAVD + tAVC$.

⁽³⁾ OeOnTime must guarantee that addresses are available. It must not exceed the availability of the first burst of data.

Figure 15-97. Synchronous Burst Read Access (Timing Parameters in Clock Cycles)

15.4.6.1.2.2 GPMC Configuration for Asynchronous Read Access

The clock runs at 104 MHz ($f = 104 \text{ MHz}$; $T = 9,615 \text{ ns}$).

[Table 15-265](#) shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

[Table 15-266](#) shows how to calculate timings for the GPMC using the memory parameters.

[Figure 15-98](#) shows the asynchronous read access.

Table 15-265. AC Characteristics for Asynchronous Read Access

| AC Read Characteristics on the Memory Side | Description | Duration (ns) |
|--------------------------------------------|-------------------------------------------|---------------|
| tCE | Read Access time from nCS low | 80 |
| tAAVDS | Address setup time to rising edge of nADV | 3 |
| tAVDP | nADV low time | 6 |
| tCAS | nCS setup time to nADV | 0 |
| tOE | Output enable to output valid | 6 |
| tOEZ | Output enable to High-Z | 7 |

Use the following formula to calculate the RdCycleTime parameter for this typical access:

$$\text{RdCycleTime} = \text{RdAccessTime} + \text{AccessCompletion} = \text{RdAccessTime} + 1 \text{ clock cycle} + \text{tOEZ}$$

- First, on the memory side, the external memory makes the data available to the output bus. This is the memory-side read access time defined in [Table 15-265](#): the number of clock cycles between the address capture (nADV rising edge) and the data valid on the output bus.

The GPMC requires some hold time to allow the data to be captured correctly and the access to be finished.

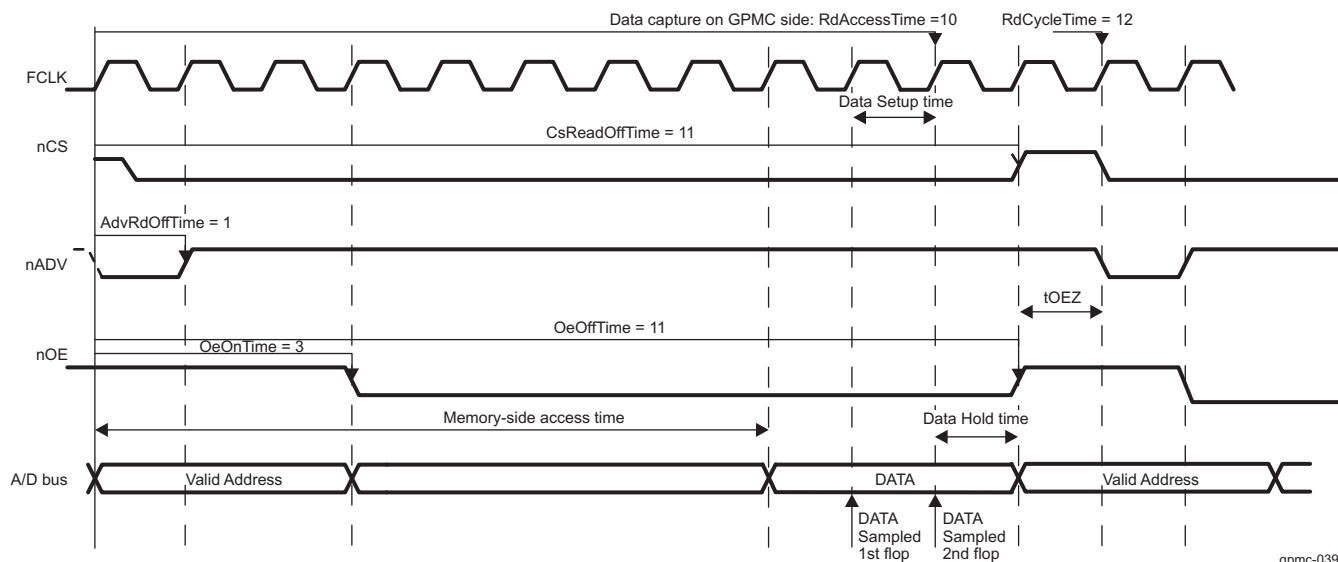

- To read the data correctly, the GPMC must be configured to meet the data setup time requirement of the memory; the GPMC module captures the data on the next rising edge. This is access time on the GPMC side.
- There must also be a data hold time for correctly reading the data (checking that there is no nOE/nCS

- deassertion while reading the data). This data hold time is 1 clock cycle (that is, AccessTime + 1).
- To complete the access, nOE/nCS signals are driven to High-Z. AccessTime + 1 + tOEZ is the read cycle time.
 - Addresses can now be relatched and a new read cycle begun.

Table 15-266. GPMC Timing Parameters for Asynchronous Read Access

| Parameter Name on GPMC side | Formula | Duration (ns) | Number of Clock Cycles (F = 104 MHz) | GPMC Register Configurations |
|-----------------------------|---------------------------------------------|-------------------------|--------------------------------------|------------------------------|
| ClkActivationTime | | n/a (asynchronous mode) | | |
| AccessTime | round max (tCE) | 80 | 10 | ACCESSTIME = 0x0A |
| PageBurstAccess Time | n/a (single access) | | | |
| RdCycleTime | AccessTime + 1cycle + tOEZ | 96, 615 | 12 | RDCYCLETIME = 0x0C |
| CsOnTime | tCAS | 0 | 0 | CSONTIME = 0x0 |
| CsReadOffTime | AccessTime + 1 cycle | 89, 615 | 11 | CSRDOFFTIME = 0x0B |
| AdvOnTime | tAAVDS | 3 | 1 | ADVONTIME = 0x1 |
| AdvRdOffTime | tAAVDS + tAVDP | 9 | 1 | ADVRDOFFTIME = 0x01 |
| OeOnTime | OeOnTime >= AdvRdOffTime (multiplexed mode) | - | 3 for instance | OEONTIME = 0x3 |
| OeOffTime | AccessTime + 1cycle | 89, 615 | 11 | OEOFFTIME = 0x0B |

Figure 15-98. Asynchronous Single Read Access (Timing Parameters in Clock Cycles)

gpmc-039

15.4.6.1.2.3 GPMC Configuration for Asynchronous Single Write Access

The clock runs at 104 MHz: (f = 104 MHz; T = 9, 615 ns).

Table 15-268 shows how to calculate timings for the GPMC using the memory parameters.

Table 15-267 shows the timing parameters (on the memory side) that determine the parameters on the GPMC side.

Figure 15-99 shows the synchronous burst write access.

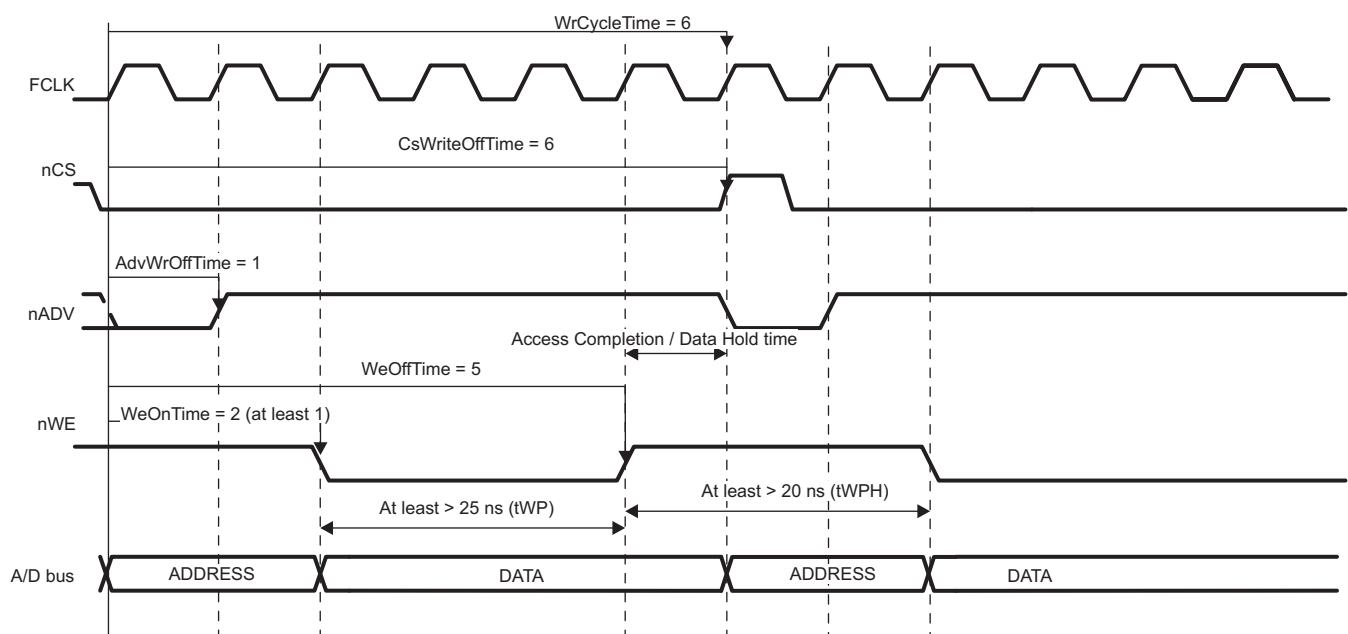

Table 15-267. AC Characteristics for Asynchronous Single Write (Memory Side)

| AC Characteristics on the Memory Side | Description | Duration (ns) |
|---------------------------------------|------------------------|---------------|
| tWC | Write cycle time | 60 |
| tAVDP | nADV low time | 6 |
| tWP | Write pulse width | 25 |
| tWPH | Write pulse width high | 20 |
| tCS | nCS setup time to nWE | 3 |
| tCAS | nCS setup time to nADV | 0 |
| tAVSC | nADV setup time | 3 |

For asynchronous single write access, write cycle time is $WrCycleTime = WeOffTime + AccessCompletion = WeOffTime + 1$. For the AccessCompletion, the GPMC requires 1 cycle of data hold time (nCS deassertion).

Table 15-268. GPMC Timing parameters for Asynchronous Single Write

| Parameter Name on GPMC side | Formula | Duration (ns) | Number of Clock Cycles (F = 104 MHz) | GPMC Registers Configuration |
|-----------------------------|------------------------------------------------------------------------------|-------------------------|--------------------------------------|------------------------------|
| ClkActivationTime | | n/a (asynchronous mode) | | |
| AccessTime | Applicable only to WAITMONITORING (the value is the same as for read access) | | | |
| PageBurstAccessTime | | n/a (single access) | | |
| WrCycleTime | $WeOffTime + AccessCompletion$ | 57, 615 | 6 | WRCYCLETIME = 0x06 |
| CsOnTime | tCAS | 0 | 0 | CSONTIME = 0x0 |
| CsWrOffTime | $WeOffTime + 1$ | 57, 615 | 6 | CSWROFFTIME = 0x06 |
| AdvOnTime | tAVSC | 3 | 1 | ADVONTIME = 0x1 |
| AdvWrOffTime | $tAVSC + tAVDP$ | 9 | 1 | ADVWROFFTIME = 0x01 |
| WeOnTime | tCS | 3 | 1 | WEONTIME = 0x1 |
| WeOffTime | $tCS + tWP + tWPH$ | 48 | 5 | WEOFFTIME = 0x05 |

Figure 15-99. Asynchronous Single Write Access (Timing Parameters in Clock Cycles)

gpmc-040

15.4.6.2 How to choose a suitable memory to use with the GPMC

This section is intended to help the user select a suitable memory device to interface with the GPMC controller.

15.4.6.2.1 Supported Memories or Devices

NAND flash and NOR flash architectures are the two flash technologies. The GPMC supports various types of external memory or device, basically any one that supports NAND or NOR protocols:

- 8- and 16-bit width asynchronous or synchronous memory or device (8-bit: non burst device only)
- 16-bit address and data multiplexed NOR flash devices (pSRAM, OneNAND™, ...)
- 8- and 16-bit NAND flash device

NOTE: Non-multiplexed NOR flash devices are supported by the GPMC but their usage is highly limited. As only ten address pins are available on the GPMC interface, the maximum device size supported is 2KB.

15.4.6.2.1.1 Memory Pin Multiplexing

This section highlights the interfacing differences of the GPMC supported memories.

Table 15-269. Supported memories interfaces

| Function | 16-bit Address/Data muxed pSRAM or NOR Flash ⁽¹⁾ | OneNAND | 16-bit NAND | 8-bit NAND |
|-------------|-------------------------------------------------------------|---------|-------------|------------|
| gpmc_a[25] | A26 | | | |

15.4.6.2.1.2 NAND Interface Protocol

NAND flash architecture, introduced in 1989, is a flash technology. NAND is a page-oriented memory device, that is, read and write accesses are done by pages. NAND achieves great density by sharing common areas of the storage transistor, which creates strings of serially connected transistors (in NOR devices, each transistor stands alone). Thanks to its high density NAND is best suited to devices requiring high capacity data storage, such as pictures, music, or data files. NAND non-volatility, makes of it a good storage solution for many applications where mobility, low power, and speed are key factors. Low pin count and simple interface are other advantages of NAND.

Table 15-270 summarizes the NAND interface signals level applied to external device or memories.

Table 15-270. NAND Interface Bus Operations Summary

| Bus operation | CLE | ALE | nCE | nWE ⁽¹⁾ | nRE ⁽¹⁾ | nWP |
|-----------------------|-----|-----|------------------|--------------------|--------------------|--------------------|
| Read (cmd input) | H | L | L | RE | H | x |
| Read (add input) | L | H | L | RE | H | x |
| Write (cmd input) | H | L | L | RE | H | H |
| Write (add input) | L | H | L | RE | H | H |
| Data input | L | L | L | RE | H | H |
| Data output | L | L | L | H | FE | x |
| Busy (during read) | x | x | H ⁽²⁾ | H ⁽²⁾ | H ⁽²⁾ | x |
| Busy (during program) | x | x | x | x | x | H |
| Busy (during erase) | x | x | x | x | x | H |
| Write protect | x | x | x | x | x | L |
| Stand-by | x | x | H | x | x | H/L ⁽³⁾ |

⁽¹⁾ RE stands for rising edge, FE stands for falling edge

⁽²⁾ Can be either nCE high, or WE and nRE high.

⁽³⁾ nWP should be biased to CMOS high or CMOS low for standby

15.4.6.2.1.3 NOR Interface Protocol

NOR flash architecture, introduced in 1988, is a flash technology. Unlike NAND which is a sequential access device, NOR is directly addressable, that is, is designed to be a random access device. NOR is best suited to devices used to store and run code or firmware, usually in small capacities. While NOR has fast read capabilities it has slow write and erase functions compared to NAND architecture.

[Table 15-271](#) summarizes the NOR interface signals level applied to external device or memories.

Table 15-271. NOR Interface Bus Operations Summary

| Bus operation | CLK | nADV | nCS | nOE | nWE | WAIT | DQ[15:0] |
|----------------------|---------|------|-----|-----|-----|----------|----------|
| Read (asynchronous) | x | L | L | L | H | Asserted | Output |
| Read (synchronous) | Running | L | L | L | H | Driven | Output |
| Read (burst suspend) | Halted | x | L | H | H | Active | Output |
| Write | x | L | L | H | L | Asserted | Input |
| Output disable | x | x | L | H | H | Asserted | High-Z |
| Standby | x | x | H | x | x | High-Z | High-Z |

15.4.6.2.1.4 Other Technologies

Other supported device type interact with the GPMC through the NOR interface protocol.

OneNAND™ is a high density and low-power memory device. OneNAND™ is based on single- or multi-level-cell NAND core with SRAM and logic, and interfaces as a synchronous NOR Flash, plus has synchronous write capability. It reads faster than conventional NAND and write faster than conventional NOR flash. Hence, it is appropriate for both mass storage and code storage.

pSRAM stands for pseudo-static random access memory. pSRAM is a low-power memory device for mobile applications. pSRAM is based on the DRAM cell with internal refresh and address control features, and interfaces as a synchronous NOR Flash, plus has synchronous write capability.

15.4.6.2.1.5 Supported Protocols

The GPMC supports the following interface protocols when communicating with external memory or external devices:

- Asynchronous read/write access
- Asynchronous read page access (4-8-16 Word16)
- Synchronous read/write access
- Synchronous read burst access without wrap capability (4-8-16 Word16)
- Synchronous read burst access with wrap capability (4-8-16 Word16)

15.4.6.2.2 GPMC Features and Settings

This section lists GPMC features and settings:

- Supported device type: up to four NAND or NOR protocol external memories or devices
- Operating Voltage: 1.8V;
- Maximum GPMC addressing capability: 1 GByte divided into eight chip-selects
- Maximum supported memory size: 256 MBytes (must be a power-of-2)
- Minimum supported memory size: 16 MBytes (must be a power-of-2). Aliasing occurs when addressing smaller memories.
- Data path to external memory or device: 8- and 16-bit wide
- Burst and page access: burst of 4-8-16 Word16
- Supports bus keeping
- Supports bus turn around

15.4.7 GPMC Register Manual

This section provides information about the GPMC instance in this product. [Table 15-273](#) provides a summary of the GPMC registers. The remaining parts of this section describe the registers within the module instance.

15.4.7.1 GPMC Register Summary

Table 15-272. GPMC Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|-----------|
| GPMC | 0x5000 0000 | 32 Mbytes |

Table 15-273. GPMC Registers Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | GPMC L3 Physical Address |

15.4.7.2 GPMC Register Descriptions

NOTE: All GPMC registers are aligned to 32-bit address boundaries. All register file accesses, except to [GPMC_NAND_DATA_i](#) register, are little endian. If the [GPMC_NAND_DATA_i](#) register location is accessed, the endianness is access-dependent.

In the whole section *i* corresponds to the chip-select number, *i* = 0 to 7.

Table 15-274. GPMC_REVISION

| | | |
|-------------------------|----------------------------------------------|----------------------|
| Address Offset | 0x0000 0000 | |
| Physical Address | 0x5000 0000 | Instance GPMC |
| Description | This register contains the IP revision code. | |
| Type | R | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|

| | | |
|-------------------------|--------------------------------------------------------------------|----------------------|
| Address Offset | 0x0000 0010 | |
| Physical Address | 0x5000 0010 | Instance GPMC |
| Description | This register controls the various parameters of the Interconnect. | |
| Type | RW | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|-----------|----------|-----------|----------|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RESERVED | | | | | | | | | | | | | | | | | | | | | | | | | | | | SIDLEMODE | RESERVED | SOFTRESET | AUTOIDLE |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-----------|
| 31:5 | RESERVED | Write 0s for future compatibility. Reads return 0s. | RW | 0x0000000 |
| 4:3 | SIDLEMODE | 0x0: Force-idle. An idle request is acknowledged unconditionally 0x1: No-idle. An idle request is never acknowledged 0x2: Smart-idle. Acknowledgment to an idle request is given based on the internal activity of the module 0x3: Do not use | RW | 0x0 |
| 2 | RESERVED | Write 0 for future compatibility Reads returns 0 | RW | 0x0 |
| 1 | SOFTRESET | Software reset. Set this bit to 1 triggers a module reset. This bit is automatically reset by hardware. During reads, it always returns 0. 0x0: Normal mode 0x1: The module is reset | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 0 | AUTOIDLE | Internal Interface clock gating strategy 0x0: Interface clock is free-running 0x1: Automatic Interface clock gating strategy is applied, based on the Interconnect activity | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|----------|
| 31:11 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x000000 |
| 10 | WAIT2EDGEDETECTIONSTATUS | Status of the Wait2 Edge Detection interrupt Read 0x0: A transition on WAIT2 input pin has not been detected Write 0x0: WAIT2EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT2 input pin has been detected Write 0x1: WAIT2EDGEDETECTIONSTATUS bit is reset | RW | 0x0 |
| 9 | WAIT1EDGEDETECTIONSTATUS | Status of the Wait1 Edge Detection interrupt Read 0x0: A transition on WAIT1 input pin has not been detected Write 0x0: WAIT1EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT1 input pin has been detected Write 0x1: WAIT1EDGEDETECTIONSTATUS bit is reset | RW | 0x0 |
| 8 | WAIT0EDGEDETECTIONSTATUS | Status of the Wait0 Edge Detection interrupt Read 0x0: A transition on WAIT0 input pin has not been detected Write 0x0: WAIT0EDGEDETECTIONSTATUS bit unchanged Read 0x1: A transition on WAIT0 input pin has been detected Write 0x1: WAIT0EDGEDETECTIONSTATUS bit is reset | RW | 0x0 |
| 7:2 | RESERVED | Write 0s for future compatibility. Read returns 0s. | RW | 0x00 |
| 1 | TERMINALCOUNTSTATUS | Status of the TerminalCountEvent interrupt Read 0x0: Indicates that CountValue is greater than 0 Write 0x0: TERMINALCOUNTSTATUS bit unchanged Read 0x1: Indicates that CountValue is equal to 0 Write 0x1: TERMINALCOUNTSTATUS bit is reset | RW | 0x0 |
| 0 | FIFOEVENTSTATUS | Status of the FIFOEvent interrupt Read 0x0: Indicates than less than GPMC_PREFETCH_STATUS [16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and less than FIFOTHRESHOLD bytes free places are available in write-posting mode. Write 0x0: FIFOEVENTSTATUS bit unchanged Read 0x1: Indicates than at least GPMC_PREFETCH_STATUS [16] FIFOTHRESHOLDSTATUS bytes are available in prefetch mode and at least FIFOTHRESHOLD bytes free places are available in write-posting mode. Write 0x1: FIFOEVENTSTATUS bit is reset | RW | 0x0 |

15.5 Error Location Module

15.5.1 Error Location Module Overview

Non-managed NAND flash memories can be dense and nonvolatile in their own nature, but error-prone. When reading from NAND flash memories, some level of error-correction is required. In the case of NAND modules with no internal correction capability, sometimes referred to as *bare NANDs*, the correction process is delegated to the memory controller.

The general-purpose memory controller (GPMC) probes data read from an external NAND flash and uses this to compute checksum-like information, called syndrome polynomials, on a per-block basis. Each syndrome polynomial gives a status of the read operations for a full block, including 512 bytes of data, parity bits, and an optional spare-area data field, with a maximum block size of 1023 bytes. Computation is based on a Bose-Chaudhuri-Hocquenghem (BCH) algorithm. The error-location module (ELM) extracts error addresses from these syndrome polynomials.

Based on the syndrome polynomial value, the ELM can detect errors, compute the number of errors, and give the location of each error bit. The actual data is not required to complete the error-correction algorithm. Errors can be reported anywhere in the NAND flash block, including in the parity bits.

The maximum acceptable number of errors that can be corrected depends on a programmable configuration parameter. 4-, 8-, and 16-bit error-correction levels are supported. The ELM relies on a static and fixed definition of the generator polynomial for each error-correction level that corresponds to the generator polynomials defined in the GPMC (there are three fixed polynomial for the three correction error levels). A larger number of errors than the programmed error-correction level may be detected, but the ELM cannot correct them all. The offending block is then tagged as *uncorrectable* in the associated computation exit status register. If the computation is successful, that is, if the number of errors detected does not exceed the maximum value authorized for the chosen correction capability, the exit status register contains the information on the number of detected errors.

When the error-location process completes, an interrupt is triggered to inform the central processing unit (CPU) that its status can be checked. The number of detected errors and their locations in the NAND block can be retrieved from the module through register accesses.

15.5.1.1 ELM Features

The ELM has the following features:

- 4, 8, and 16 bits per 512-byte block error-location based on BCH algorithms
- Eight simultaneous processing contexts
- Page-based and continuous modes
- Interrupt generation on error-location process completion:
 - When the full page has been processed in page mode
 - For each syndrome polynomial in continuous mode

15.5.2 ELM Integration

The ELM extracts error addresses from generated syndrome polynomials.

The ELM is used with the GPMC. Syndrome polynomials generated on-the-fly when reading a NAND flash page and stored in GPMC registers are passed to the ELM. The microprocessor unit (MPU) can then correct the data block by flipping the bits to which the ELM error-location outputs point.

Figure 15-100 shows the integration of the ELM subsystem in the device.

15.5.3 ELM Functional Description

The ELM is designed around the error-location engine, which handles the computation based on the input syndrome polynomials.

The ELM maps the error-location engine to a standard interconnect interface by using a set of registers to control inputs and outputs.

15.5.3.1 ELM Software Reset

To perform a software reset, write a 1 to the [ELM_SYSCONFIG\[1\]](#) SOFTRESET bit. The [ELM_SYSSTATUS\[0\]](#) RESETDONE bit indicates that the software reset is complete when its value is 1. When the software reset completes, the [ELM_SYSCONFIG\[1\]](#) SOFTRESET bit is automatically reset.

15.5.3.2 ELM Power Management

[Table 15-349](#) describes the power-management features available to the ELM module.

NOTE:

- For information about source clock gating and sleep/wake-up transitions description, see the [Section 3.6.8](#), *CD_L4_PER Clock Domain* in [Chapter 3](#), *Power, Reset, and Clock Management*.
 - For a general description of EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.6](#) *Clock Management* in [Chapter 3](#), *Power, Reset, and Clock Management*
-

Table 15-349. Local Power Management Features

| Feature | Registers | Description |
|------------------------|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| Clock autogating | ELM_SYSCONFIG [0] AUTOGATING bit | This bit allows a local power optimization inside the module by gating the ELM_FCLK clock upon the interface activity. |
| Slave idle modes | ELM_SYSCONFIG [4:3] SIDLEMODE bit field | Force-idle, No-idle, and Smart-idle modes are available. |
| Clock activity | ELM_SYSCONFIG [8] CLOCKACTIVITY bit | The clock can be switched-off or maintained during the wake-up period. |
| Master Standby modes | N/A | |
| Global Wake-up Enable | N/A | |
| Wake-up Sources Enable | N/A | |

CAUTION

The PRCM module has no hardware means of reading CLOCKACTIVITY settings. Thus, software must ensure consistent programming between the ELM CLOCKACTIVITY and ELM clock PRCM control bits. For a description of the ClockActivity feature, see [Chapter 3, Power, Reset, and Clock Management](#).

15.5.3.3 ELM Interrupt Requests

[Table 15-350](#) lists the event flags, and their masks, that can cause module interrupts.

Table 15-350. Events

| Event Flag | Event Mask | Map to | Description |
|--------------------------------------------------|------------------------------------------------------|---------|----------------------------------------------------|
| ELM_IRQSTATUS [8] PAGE_VALID | ELM_IRQENABLE [8] PAGE_MASK | ELM_IRQ | Page interrupt |
| ELM_IRQSTATUS [7] LOC_VALID_7 | ELM_IRQENABLE [7] LOCATION_MASK_7 | ELM_IRQ | Error-location interrupt for syndrome polynomial 7 |
| ELM_IRQSTATUS [6] LOC_VALID_6 | ELM_IRQENABLE [6] LOCATION_MASK_6 | ELM_IRQ | Error-location interrupt for syndrome polynomial 6 |
| ELM_IRQSTATUS [5] LOC_VALID_5 | ELM_IRQENABLE [5] LOCATION_MASK_5 | ELM_IRQ | Error-location interrupt for syndrome polynomial 5 |
| ELM_IRQSTATUS [4] LOC_VALID_4 | ELM_IRQENABLE [4] LOCATION_MASK_4 | ELM_IRQ | Error-location interrupt for syndrome polynomial 4 |
| ELM_IRQSTATUS [3] LOC_VALID_3 | ELM_IRQENABLE [3] LOCATION_MASK_3 | ELM_IRQ | Error-location interrupt for syndrome polynomial 3 |
| ELM_IRQSTATUS [2] LOC_VALID_2 | ELM_IRQENABLE [2] LOCATION_MASK_2 | ELM_IRQ | Error-location interrupt for syndrome polynomial 2 |
| ELM_IRQSTATUS [1] LOC_VALID_1 | ELM_IRQENABLE [1] LOCATION_MASK_1 | ELM_IRQ | Error-location interrupt for syndrome polynomial 1 |
| ELM_IRQSTATUS [0] LOC_VALID_0 | ELM_IRQENABLE [0] LOCATION_MASK_0 | ELM_IRQ | Error-location interrupt for syndrome polynomial 0 |

15.5.3.4 Processing Initialization

[ELM_LOCATION_CONFIG](#) global setting parameters must be set before using the error-location engine. The [ELM_LOCATION_CONFIG](#)[1:0] ECC_BCH_LEVEL bit defines the error-correction level used (4-, 8-, or 16-bit error-correction). The [ELM_LOCATION_CONFIG](#)[26:16] ECC_SIZE bit field defines the maximum buffer length beyond which the engine processing no longer looks for errors.

The CPU can choose to use the ELM in continuous mode or page mode. If all [ELM_PAGE_CTRL](#)[i] SECTOR_i bits are reset (i is the syndrome polynomial number, i = 0 to 7), continuous mode is used. In any other case, page mode is implicitly selected.

- Continuous mode: Each syndrome polynomial is processed independently – results for a syndrome

can be retrieved and acknowledged at any time, whatever the status of the other seven processing contexts.

- Page mode: Syndrome polynomials are grouped into atomic entities – only one page can be processed at any given time, even if all eight contexts are not used for this page. Unused contexts are lost and cannot be affected to any other processing. The full page must be acknowledged and cleared before moving to the next page.

For completion interrupts to be generated correctly, all [ELM_IRQENABLE\[i\]](#) LOCATION_MASK_i bits (i = 0 to 7) must be forced to 0 when in page mode, and set to 1 in continuous mode. Additionally, the [ELM_IRQENABLE\[8\]](#) PAGE_MASK bit must be set to 1 when in page mode.

The CPU initiates error-location processing by writing a syndrome polynomial into one of the eight possible register sets. Each of these register sets includes seven registers: [ELM_SYNDROME_FRAGMENT_0_i](#) to [ELM_SYNDROME_FRAGMENT_6_i](#). The first six registers can be written in any order, but [ELM_SYNDROME_FRAGMENT_6_i](#) must be written last because it includes the validity bit, which instructs the ELM that this syndrome polynomial must be processed (the [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID bit).

As soon as one validity bit is asserted ([ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID = 0x1, with i = 0 to 7), error-location processing can start for the corresponding syndrome polynomial. The associated [ELM_LOCATION_STATUS_i](#) and [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#) registers are not reset (i = 0 to 7). The software must not consider them until the corresponding [ELM_IRQSTATUS\[i\]](#) LOC_VALID_i bit is set.

15.5.3.5 Processing Sequence

While the error-location engine is busy processing one syndrome polynomial, further syndrome polynomials can be written. They are processed when the current processing completes.

The engine completes early when:

- No error is detected; that is, when the [ELM_LOCATION_STATUS_i\[8\]](#) ECC_CORRECTABLE bit is set to 1 and the [ELM_LOCATION_STATUS_i\[4:0\]](#) ECC_NB_ERRORS bit field is set to 0x0.
- Too many errors are detected; that is, when the [ELM_LOCATION_STATUS_i\[8\]](#) ECC_CORRECTABLE bit is set to 0 while the [ELM_LOCATION_STATUS_i\[4:0\]](#) ECC_NB_ERRORS bit field is set with the value output by the error-location engine. The reported number of errors is not ensured if ECC_CORRECTABLE is 0.

If the engine completes early, the associated error-location registers [ELM_ERROR_LOCATION_0_i](#) to [ELM_ERROR_LOCATION_15_i](#) are not updated (i = 0 to 7).

In all other cases, the engine goes through the entire error-location process. Each time an error-location is found, it is logged in the associated ECC_ERROR_LOCATION bit field. The first error detected is logged in the [ELM_ERROR_LOCATION_0_i\[12:0\]](#) ECC_ERROR_LOCATION bit field; the second in the [ELM_ERROR_LOCATION_1_i\[12:0\]](#) ECC_ERROR_LOCATION bit field, and so on.

Table 15-351. ELM_LOCATION_STATUS_i Value Decoding Table

| ECC_CORRECTABLE Value | ECC_NB_ERRORS Value | Status | Number of Errors Detected | Action Required |
|-----------------------|---------------------|--------|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| 1 | 0 | OK | 0 | None |
| 1 | ≠ 0 | OK | ECC_NB_ERRORS | Correct the data buffer read based on the ELM_ERROR_LOCATION_0_i to ELM_ERROR_LOCATION_15_i results. |
| 0 | Any | Failed | Unknown | Software-dependant |

15.5.3.6 Processing Completion

When the processing for a given syndrome polynomial completes, its [ELM_SYNDROME_FRAGMENT_6_i\[16\]](#) SYNDROME_VALID bit is reset. It must not be set again until the exit status registers, [ELM_LOCATION_STATUS_i](#) (i = 0 to 7), for this processing are checked. Failure to comply with this rule leads to potential loss of the first polynomial process data output.

The error-location engine signals the process completion to the ELM. When this event is detected, the corresponding `ELM_IRQSTATUS[i] LOC_VALID_i` bit is set ($i = 0$ to 7). The processing-exit status is available from the associated `ELM_LOCATION_STATUS_i` register, and error locations are stored in order in the `ECC_ERROR_LOCATION` fields. The software must only read valid error-location registers based on the number of errors detected and located.

Immediately after the error-location engine completes, a new syndrome polynomial can be processed, if any is available, as reported by the `ELM_SYNDROME_FRAGMENT_6_i[16] SYNDROME_VALID` validity bit, depending on the configured error-correction level. If several syndrome polynomials are available, a round-robin arbitration is used to select one for processing.

In continuous mode (that is, all bits in `ELM_PAGE_CTRL` are reset), an interrupt is triggered whenever a `ELM_IRQSTATUS[i] LOC_VALID_i` bit is asserted. The CPU must read the `ELM_IRQSTATUS` register to determine which polynomial is processed and retrieve the exit status and error locations (`ELM_LOCATION_STATUS_i` and `ELM_ERROR_LOCATION_0_i` to `ELM_ERROR_LOCATION_15_i`). When done, the CPU must clear the corresponding `ELM_IRQSTATUS[i] LOC_VALID_i` bit by writing it to 1. Other status bits must be written to 0 so that other interrupts are not unintentionally cleared. When using this mode, the `ELM_IRQSTATUS[8] PAGE_VALID` interrupt is never triggered.

In page mode, the module does not trigger interrupts for the processing completion of each polynomial because the `ELM_IRQENABLE[i] LOCATION_MASK_i` bits are cleared. A page is defined using the `ELM_PAGE_CTRL` register. Each `SECTOR_i` bit set means the corresponding polynomial i is part of the page processing. A page is fully processed when all tagged polynomials have been processed, as logged in the `ELM_IRQSTATUS[i] LOC_VALID_i` bit fields. The module triggers an `ELM_IRQSTATUS[8] PAGE_VALID` interrupt whenever it detects that the full page has been processed. To make sure the next page can be correctly processed, all status bits in the `ELM_IRQSTATUS` register must be cleared by using a single atomic-write access.

NOTE: Do not modify page setting parameters in the `ELM_PAGE_CTRL` register unless the engine is idle, no polynomial input is valid, and all interrupts have been cleared.

Because no polynomial-level interrupt is triggered in page mode, polynomials cleared in the `ELM_PAGE_CTRL[i] SECTOR_i` bit fields ($i = 0$ to 7) are processed as usual, but are essentially ignored. The CPU must manually poll the `ELM_IRQSTATUS` bits to check for their status.

15.5.4 ELM Basic Programming Model

15.5.4.1 ELM Low Level Programming Model

15.5.4.1.1 Processing Initialization

Table 15-352. ELM Processing Initialization

| Step | Register/ Bit Field / Programming Model | Value |
|---------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|-----------|
| Resets the module | <code>ELM_SYSCONFIG[1] SOFTRESET</code> | 0x1 |
| Wait until reset is done. | <code>ELM_SYSSTATUS[0] RESETDONE</code> | 0x1 |
| Configure the slave interface power management. | <code>ELM_SYSCONFIG[4:3] SIDLEMODE</code> | Set value |
| Defines the error-correction level used | <code>ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL</code> | Set value |
| Defines the maximum buffer length | <code>ELM_LOCATION_CONFIG[26:16] ECC_SIZE</code> | Set value |
| Sets the ELM in continuous mode or page mode | <code>ELM_PAGE_CTRL</code> | Set value |
| If continuous mode is used | All <code>ELM_PAGE_CTRL[i] SECTOR_i</code> ($i = 0$ to 7) | 0x0 |
| Enables interrupt for syndrome polynomial i | <code>ELM_IRQENABLE[i] LOCATION_MASK_i</code> | 0x1 |
| else (page mode is used) | One syndrome polynomial i is set <code>ELM_PAGE_CTRL[i] SECTOR_i</code> ($i = 0$ to 7) | 0x1 |
| Disable all interrupts for syndrome polynomial and enable <code>PAGE_MASK</code> interrupt. | All <code>ELM_IRQENABLE[i] LOCATION_MASK_i = 0x0</code> and <code>ELM_IRQENABLE[8] PAGE_MASK = 0x1</code> | Set value |
| endif | | Set value |

Table 15-352. ELM Processing Initialization (continued)

| Step | Register/ Bit Field / Programming Model | Value |
|-----------------------------------------|------------------------------------------------------------------|-----------|
| Set the input syndrome polynomial i . | ELM_SYNDROME_FRAGMENT_0_i | Set value |
| | ELM_SYNDROME_FRAGMENT_1_i | Set value |
| | ELM_SYNDROME_FRAGMENT_5_i | Set value |
| | ELM_SYNDROME_FRAGMENT_6_i | Set value |
| Initiates the computation process | ELM_SYNDROME_FRAGMENT_6_i [16] SYNDROME_VALID | 0x1 |

15.5.4.1.2 Read Results

The engine goes through the entire error-location process and results can be read. [Table 15-353](#) and [Table 15-354](#) describe the processing completion for continuous and page modes, respectively.

Table 15-353. ELM Processing Completion for Continuous Mode

| Step | Register/ Bit Field / Programming Model | Value |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|-------|
| Wait until process is complete for syndrome polynomial i : Wait until the ELM_IRQ interrupt is generated, or poll the status register. | | |
| Read for which i the error-location process is complete. | ELM_IRQSTATUS [i] LOC_VALID_ i | 0x1 |
| if the process fails (too many errors) It is software dependant. | ELM_LOCATION_STATUS_ i [8] ECC_CORRECTABLE | 0x0 |
| else (process successful, the engine completes) | ELM_LOCATION_STATUS_ i [8] ECC_CORRECTABLE | 0x1 |
| Read the number of errors. | ELM_LOCATION_STATUS_ i [4:0] ECC_NB_ERRORS | |
| Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. It is the software responsibility to correct errors in the data buffer. | ELM_ERROR_LOCATION_0_ i [12:0] ECC_ERROR_LOCATION | |
| | ELM_ERROR_LOCATION_1_ i [12:0] ECC_ERROR_LOCATION | |
| | ... | |
| | ELM_ERROR_LOCATION_15_ i [12:0] ECC_ERROR_LOCATION | |
| endif | | |
| Clear the corresponding i interrupt. | ELM_IRQSTATUS [i] LOC_VALID_ i | 0x1 |

A new syndrome polynomial can be processed after the end of processing ([ELM_SYNDROME_FRAGMENT_6_i](#)[16] SYNDROME_VALID = 0x0) and after the exit status register check ([ELM_LOCATION_STATUS_](#) i).

Table 15-354. ELM Processing Completion for Page Mode

| Step | Register/ Bit Field / Programming Model | Value |
|---------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|-------|
| Wait until process is complete for syndrome polynomial i : Wait until the ELM_IRQ interrupt is generated, or poll the status register. | | |
| Wait for page completed interrupt: All error locations are valid. | ELM_IRQSTATUS [8] PAGE_VALID | 0x1 |
| Repeat the following actions the necessary number of times. That is, once for each valid defined block in the page. | | |
| Read the process exit status. | ELM_LOCATION_STATUS_ i [8] ECC_CORRECTABLE | |
| if the process fails (too many errors) It is software dependant. | ELM_LOCATION_STATUS_ i [8] ECC_CORRECTABLE | 0x0 |
| else (process successful, the engine completes) | ELM_LOCATION_STATUS_ i [8] ECC_CORRECTABLE | 0x1 |
| Read the number of errors. | ELM_LOCATION_STATUS_ i [4:0] ECC_NB_ERRORS | |

Table 15-354. ELM Processing Completion for Page Mode (continued)

| Step | Register/ Bit Field / Programming Model | Value |
|---------------------------------------------------------------------------------------------------------|---------------------------------------------------------|-------|
| Read the error-location bit addresses for syndrome polynomial i of the ECC_NB_ERRORS first registers. | ELM_ERROR_LOCATION_0_ i [12:0] ECC_ERROR_LOCATION | |
| | ELM_ERROR_LOCATION_1_ i [12:0] ECC_ERROR_LOCATION | |
| | ... | |
| | ELM_ERROR_LOCATION_15_ i [12:0] ECC_ERROR_LOCATION | |
| endif | | |
| End Repeat | | |
| Clear the ELM_IRQSTATUS register. | ELM_IRQSTATUS | 0x1FF |

Next page can be correctly processed after a page is fully processed, when all tagged polynomials have been processed (ELM_IRQSTATUS[i] LOC_VALID_ i = 0x1 for all syndrome polynomials i used in the page).

15.5.4.2 Use Case: ELM Used in Continuous Mode

In this example, the ELM module is programmed for an 8-bit error-correction capability in continuous mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, a non-zero polynomial syndrome is reported from the GPMC (Polynomial syndrome 0 is used in the ELM):

- P = 0x0A16ABE115E44F767BFB0D0980

Table 15-355. Use Case: Continuous Mode

| Step | Register/ Bit Field / Programming Model | Value |
|----------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------|------------|
| Resets the module | ELM_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset is done. | ELM_SYSSTATUS[0] RESETDONE | 0x1 |
| Configure the slave interface power management: Smart idle is used. | ELM_SYSCONFIG[4:3] SIDLEMODE | 0x2 |
| Defines the error-correction level used: 8 bits | ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL | 0x1 |
| Defines the maximum buffer length: 528 bytes (2x528 = 1056) | ELM_LOCATION_CONFIG[26:16] ECC_SIZE | 0x420 |
| Sets the ELM in continuous mode | ELM_PAGE_CTRL | 0 |
| Enables interrupt for syndrome polynomial 0 | ELM_IRQENABLE[0] LOCATION_MASK_0 | 0x1 |
| Set the input syndrome polynomial 0. | ELM_SYNDROME_FRAGMENT_0_ i ($i=0$) | 0xFB0D0980 |
| | ELM_SYNDROME_FRAGMENT_1_ i ($i=0$) | 0xE44F767B |
| | ELM_SYNDROME_FRAGMENT_2_ i ($i=0$) | 0x16ABE115 |
| | ELM_SYNDROME_FRAGMENT_3_ i ($i=0$) | 0x0000000A |
| Initiates the computation process | ELM_SYNDROME_FRAGMENT_6_ i [16] SYNDROME_VALID ($i=0$) | 0x1 |
| Wait until process is complete for syndrome polynomial 0: IRQ_ELM is generated or poll the status register. | | |
| Read that error-location process is complete for syndrome polynomial 0. | ELM_IRQSTATUS[0] LOC_VALID_0 | 0x1 |
| Read the process exit status: All errors were successfully located. | ELM_LOCATION_STATUS_ i [8] ECC_CORRECTABLE ($i=0$) | 0x1 |
| Read the number of errors: Four errors detected. | ELM_LOCATION_STATUS_ i [4:0] ECC_NB_ERRORS ($i=0$) | 0x4 |

Table 15-355. Use Case: Continuous Mode (continued)

| Step | Register/ Bit Field / Programming Model | Value |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------|-------|
| Read the error-location bit addresses for syndrome polynomial 0 of the 4 first registers: Errors are located in the data buffer at decimal addresses 431, 1062, 1909, 3452. | ELM_ERROR_LOCATION_0_i (i=0) | 0x1AF |
| | ELM_ERROR_LOCATION_1_i (i=0) | 0x426 |
| | ELM_ERROR_LOCATION_2_i (i=0) | 0x775 |
| | ELM_ERROR_LOCATION_3_i (i=0) | 0xD7C |
| Clear the corresponding interrupt for polynomial 0. | ELM_IRQSTATUS[0] LOC_VALID_0 | 0x1 |

The NAND flash data in the sector are seen as a polynomial of degree 4223 (number of bits in a 528 byte buffer minus 1), with each data bit being a coefficient in the polynomial. When reading from a NAND flash using the GPMC module, computation of the polynomial syndrome assumes that the first NAND word read at address 0x0 contains the highest-order coefficient in the message. Furthermore, in the 16-bit NAND word, bits are ordered from bit 7 to bit 0, then from bit 15 to bit 8. Based on this convention, an address table of the data buffer can be built. NAND memory addresses in [Table 15-356](#) are given in decimal format.

Table 15-356. 16-bit NAND Sector Buffer Address Map

| NAND Memory Address | Message bit addresses in the memory word | | | | | | | | | | | | | | | |
|---------------------|------------------------------------------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|------|

| 259 | 71 | 70 | 69 | 68 | 67 | 66 | 65 | 64 | 79 | 78 | 77 | 76 | 75 | 74 | 73 | 72 |
| 260 | 55 | 54 | 53 | 52 | 51 | 50 | 49 | 48 | 63 | 62 | 61 | 60 | 59 | 58 | 57 | 56 |
| 261 | 39 | 38 | 37 | 36 | 35 | 34 | 33 | 32 | 47 | 46 | 45 | 44 | 43 | 42 | 41 | 40 |
| 262 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 |
| 263 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 |

The table can now be used to determine which bits in the buffer were incorrect and must be flipped. In this example, the first bit to be flipped is bit 4 from the 49th byte read from memory. It is up to the processor to correctly map this word to the copied buffer and to flip this bit. The same process must be repeated for all detected errors.

15.5.4.3 Use Case: ELM Used in Page Mode

In this example, the ELM module is programmed for an 16-bit error-correction capability in page mode. After reading a 528-byte NAND flash sector (512B data plus 16B spare area) with a 16-bit interface, four non-zero polynomial syndromes are reported from the GPMC (Polynomial syndrome 0, 1, 2, and 3 are used in the ELM):

- P0 = 0xE8B0 12ADDB5A318E05BE B0693DB28330B5CC A329AA05E0B718EF
- P1 = 0xBAD0 49A0D932C22E6669 0948DF08BE093336 79C6BA10E5F935EB
- P2 = 0x69D9 B86ABCD5EC3697FA A6498FEE54556EA0 1579EF7D60BA3189
- P3 = 0x0

Table 15-357. Use Case: Page Mode

| Step | Register/ Bit Field / Programming Model | Value |
|--------------------------------------------------------------------------------|-------------------------------------------------------|------------|
| Resets the module | ELM_SYSCONFIG[1] SOFTRESET | 0x1 |
| Wait until reset is done. | ELM_SYSSTATUS[0] RESETDONE | 0x1 |
| Configure the slave interface power management: Smart idle is used. | ELM_SYSCONFIG[4:3] SIDLEMODE | 0x2 |
| Defines the error-correction level used: 16 bits | ELM_LOCATION_CONFIG[1:0] ECC_BCH_LEVEL | 0x2 |
| Defines the maximum buffer length: 528 bytes | ELM_LOCATION_CONFIG[26:16] ECC_SIZE | 0x420 |
| Sets the ELM in page mode (4 blocks in a page) | ELM_PAGE_CTRL[0] SECTOR_0 | 0x1 |
| | ELM_PAGE_CTRL[1] SECTOR_1 | 0x1 |
| | ELM_PAGE_CTRL[2] SECTOR_2 | 0x1 |

| RESERVED | | | | | | | | | | | | | | | | CLOCKACTIVITYOCP | RESERVED | | SIDLEMODE | | RESERVED | SOFTRESET | AUTOGATING | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|----------|
| 31:9 | RESERVED | Reserved | R | 0x000000 |
| 8 | CLOCKACTIVITYOCP | OCP Clock activity when module is in IDLE mode (during wake up mode period) 0x0: OCP Clock can be switch-off 0x1: OCP Clock is maintained during wake up period | RW | 0 |
| 7:5 | RESERVED | Reserved | R | 0x0 |
| 4:3 | SIDLEMODE | Slave interface power management (IDLE req/ack control) 0x0: FORCE Idle. IDLE request is acknowledged unconditionally and immediately (Default <i>Dumb</i> mode for safety) 0x1: NO idle. IDLE request is never acknowledged. 0x2: SMART Idle. The acknowledgment to an IDLE request is given based on the internal activity. 0x3: Reserved - do not use | RW | 0x2 |
| 2 | RESERVED | Reserved | R | 0 |
| 1 | SOFTRESET | Module software reset This bit is automatically reset by hardware (During reads, it always returns 0.) It has same effect as the OCP hardware reset. 0x0: Normal mode 0x1: Start soft reset sequence. | RW | 0 |
| 0 | AUTOGATING | Internal OCP clock gating strategy (no module visible impact other than saving power) 0x0: OCP clock is free-running 0x1: Automatic internal OCP clock gating strategy is applied based on the OCP interface activity. | RW | 1 |

15.6 On-Chip Memory (OCM) Subsystem

15.6.1 OCM Subsystem Overview

There are three on-chip memories in the device.

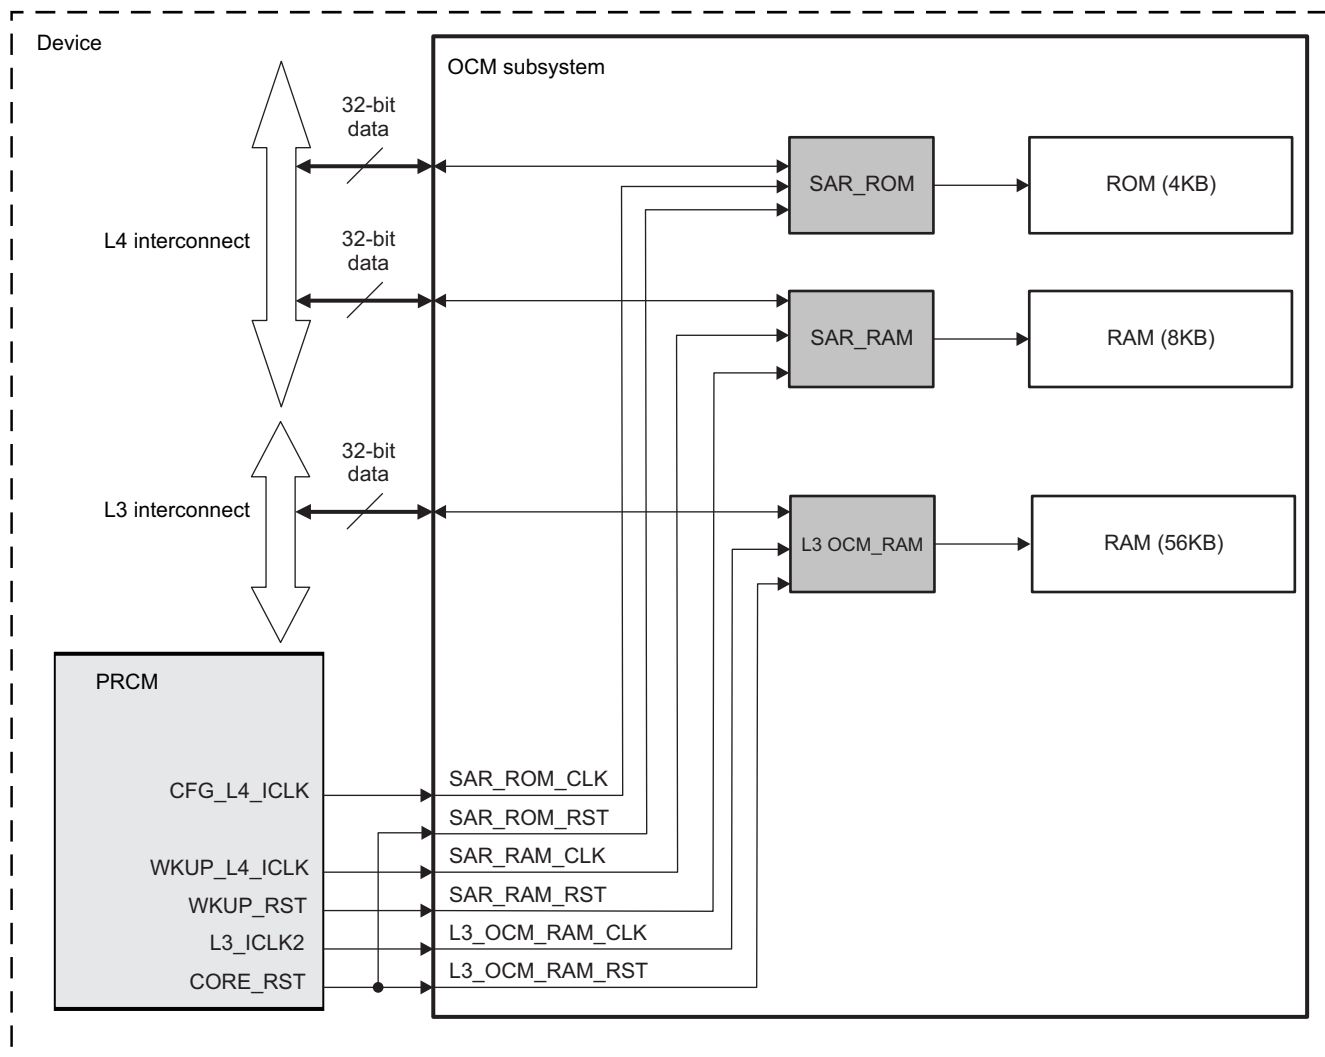

- A 4K-byte SAR read-only memory (ROM)
- A 8K-byte SAR random-access memory (RAM)
- A 56K-byte L3 static random-access memory (L3 OCM_RAM)

There are other on-chip memories located inside other subsystems (Cortex-A9 MPU, DSP IVA-HD, ABE, Cortex-M3 MPU) that are not described in the following sections. Refer to each subsystem chapter for more details.

15.6.2 OCM Subsystem Integration

Figure 15-101 shows the integration of the OCM subsystem to the device.

Figure 15-101. OCM Subsystem Integration to the Device

Ocm-004

Table 15-422 through Table 15-423 summarize the integration of the module in the device.

Table 15-422. Integration Attributes

| Module Instance | Attributes | | |

15.6.3 OCM Subsystem Functional Description

15.6.3.1 SAR ROM

This on-chip ROM contains 4K bytes of memory and a linked list of descriptors used by the system DMA (sDMA) during the restore context operation (when device transitions from OFF to ON modes).

The device-embedded SAR ROM has the following characteristics:

- 4K-bytes ROM
- 32-bit access per cycle
- Support for single and burst access transactions

The memory space of the embedded ROM starts at 0x4A05 E000 and ends at 0x4A05 FFFF (8K bytes are reserved, but only 4K bytes are used).

15.6.3.2 SAR RAM

The on-chip SAR RAM contains 8K bytes and is mapped as 4 blocks with irregular region sizes. This memory content is preserved when the device goes into OFF mode (as long as the wake-up voltage domain remains supplied). It is used as context-saving memory to be written by the software, so that the sDMA restores its saved content when the device transitions from OFF to ON mode. Locations not used by the sDMA can be used as a scratch-pad memory by the software. It is mapped on the wake-up voltage domain.

The device-embedded SAR RAM has the following characteristics:

- Support for single-access transactions
 - Operates at full L4-PER interconnect clock frequency
 - 32-bit access per cycle

The SAR RAM space is at the following location:

- SAR space 1 (4KB): Starts at 0x4A32 6000 and ends at 0x4A32 6FFF
- SAR space 2 (1KB): Starts at 0x4A32 7000 and ends at 0x4A32 73FF
- SAR space 3 (2KB): Starts at 0x4A32 8000 and ends at 0x4A32 87FF
- SAR space 4 (1KB): Starts at 0x4A32 9000 and ends at 0x4A32 93FF

15.6.3.3 L3 OCM_RAM

The on-chip L3 OCM_RAM contains 56K bytes of RAM, partitioning is defined by the L3 firewall logic.

The device-embedded L3 OCM_RAM has the following characteristics:

- Support for single and burst access transactions:
 - Operates at full L3 interconnect clock frequency
 - Fully pipelined, one 32-bit access per cycle
- Restricted access support based on:
 - A region-based partitioning (refer to L3 firewall description)
 - The module owner of the access, with respect to its read and write permissions to that region
 - The transaction attributes of the access, with respect to the region permission properties. See [Section 13.2, L3 Interconnect](#) for details.

The memory space of the embedded RAM starts at 0x4030 0000 and ends at 0x4030 DFFF.

This chapter describes the system direct memory access (sDMA) module.

| Topic | Page |

| 16.1 sDMA Module Overview | 3528 |
| 16.2 sDMA Controller Environment | 3530 |
| 16.3 sDMA Module Integration | 3532 |
| 16.4 sDMA Functional Description | 3537 |
| 16.5 sDMA Basic Programming Model | 3570 |
| 16.6 sDMA Register Manual | 3579 |

16.1 sDMA Module Overview

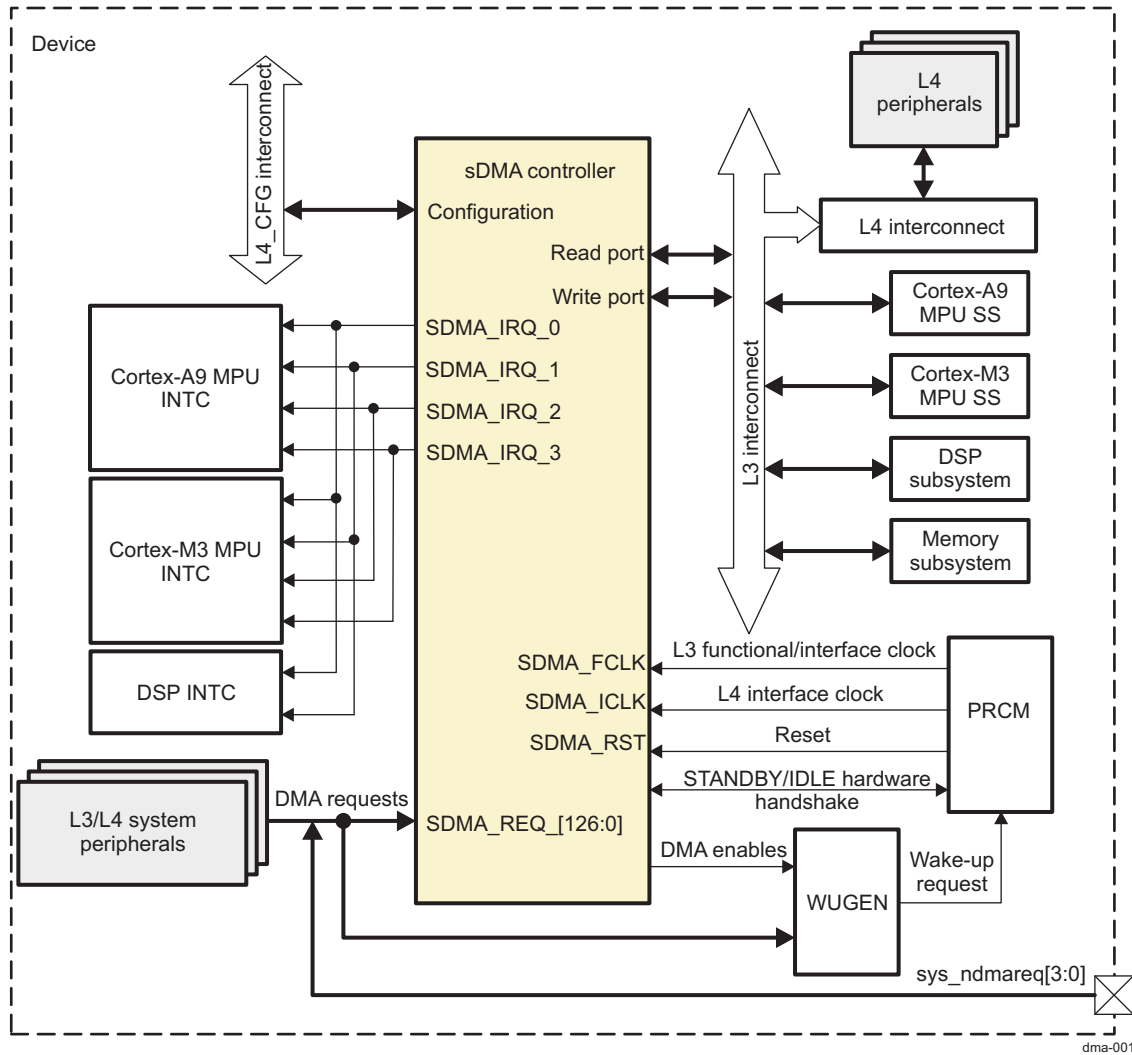

The system direct memory access (sDMA), also called DMA4, performs high-performance data transfers between memories and peripheral devices without microprocessor unit (MPU) or digital signal processor (DSP) support during transfer. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

The DMA controller includes the following main features:

- Data transfer support in either direction between:
 - Memory and memory
 - Memory and peripheral device
- 32 logical DMA channels supporting:
 - Multiple concurrent transfers
 - Independent transfer profile for each channel
 - 8-bit, 16-bit, or 32-bit data element transfer size
 - Software-triggered or hardware-synchronized transfers
 - Flexible source and destination address generation
 - Burst read and write
 - Chained multiple-channel transfers
 - Endianism conversion
 - Draining
 - Linked-list support for descriptor types 1, 2, and 3
- First-come, first-serve DMA scheduling with fixed priority
- Up to 127 DMA requests
- Constant fill
- Transparent copy
- Four programmable interrupt request output lines
- FIFO depth: 256 × 64-bit
- Data buffering
- FIFO budget allocation
- Power-management support
- Auto-idle power-saving support
- Implementation of retention flip-flops (RFFs) to support dynamic power switching (DPS) between system power modes without MPU involvement. For more information about DPS, see [Section 3.1.2.3, *Dynamic Power Switching \(DPS\)*](#).

Figure 16-1 shows an overview of the sDMA module.

Figure 16-1. sDMA Overview

The sDMA module has three ports: one read, one write, and one configuration port and provides multiple logical channel support. A dynamically allocated FIFO queue memory pool provides buffering between the read and write ports, which are multithreaded (two threads for the write port and four threads for the read port); this means that each transaction is flagged by a thread ID (0, 1, 2, or 3) in the request direction and in the response direction. This allows the read port to have four outstanding requests at a time. The write port has two threads budget available.

The MPU (or DSP) configures the sDMA through the L4-CFG interconnect.

16.2 sDMA Controller Environment

The sDMA controller supports external DMA requests through the sys_ndmareq[3:0] pins (see [Table 16-1](#)). A logical channel can be configured to respond to an external synchronization request.

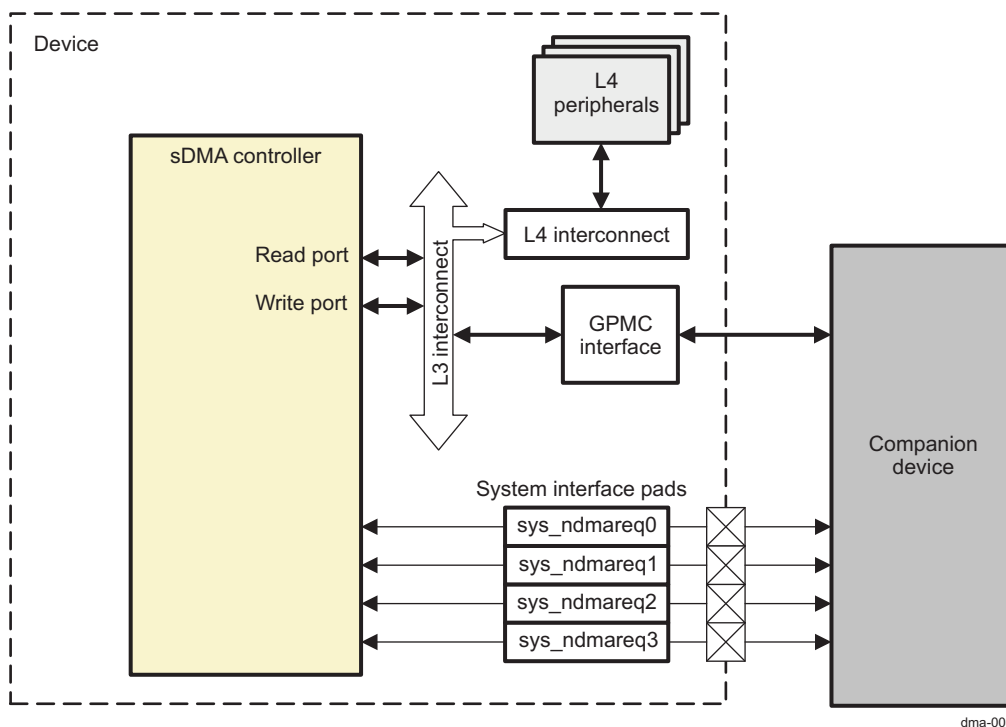

Table 16-1. External sDMA Request Signals

| Signal Name | I/O ⁽¹⁾ | Description | Reset Value |
|--------------|--------------------|-------------------------------------------|-------------|
| sys_ndmareq0 | I | External DMA request 0 (system expansion) | Z |
| sys_ndmareq1 | I | External DMA request 1 (system expansion) | Z |
| sys_ndmareq2 | I | External DMA request 2 (system expansion) | Z |
| sys_ndmareq3 | I | External DMA request 3 (system expansion) | Z |

⁽¹⁾ I = Input; O = Output; I/O = Bidirectional

[Figure 16-2](#) shows an example of how to use the external hardware DMA request pins in the sDMA environment.

Figure 16-2. Example of External DMA Requests Use

An external device can use the external DMA request pins to start a logical channel transfer over the general-purpose memory controller (GPMC) interface. The transfer can be a memory-to-memory transfer in which the source memory is in the external device.

By default, the external DMA request signals are not available on external pins after a cold reset. For more information about multiplexing out the four signal lines to pins, see [Chapter 18, Control Module](#).

All 127 DMA request lines are transition-sensitive.

For a transition-sensitive DMA request (see [Figure 16-3](#)), the line must be maintained low (asserted) until the first DMA access is complete, after which the line must be maintained high (deasserted) for greater than one clock cycle (DMA_L3_ICLK):

- When the deassertion time is less than one clock cycle, the sDMA might not detect the deassertion.
- When the channel is enabled one cycle after a DMA request is disabled, the channel detects the DMA request and starts the corresponding transfer.
- When the channel is enabled two cycles after the DMA request is disabled, the channel does not

detect the DMA request.

Figure 16-3. Transition-Sensitive DMA Request Scheme

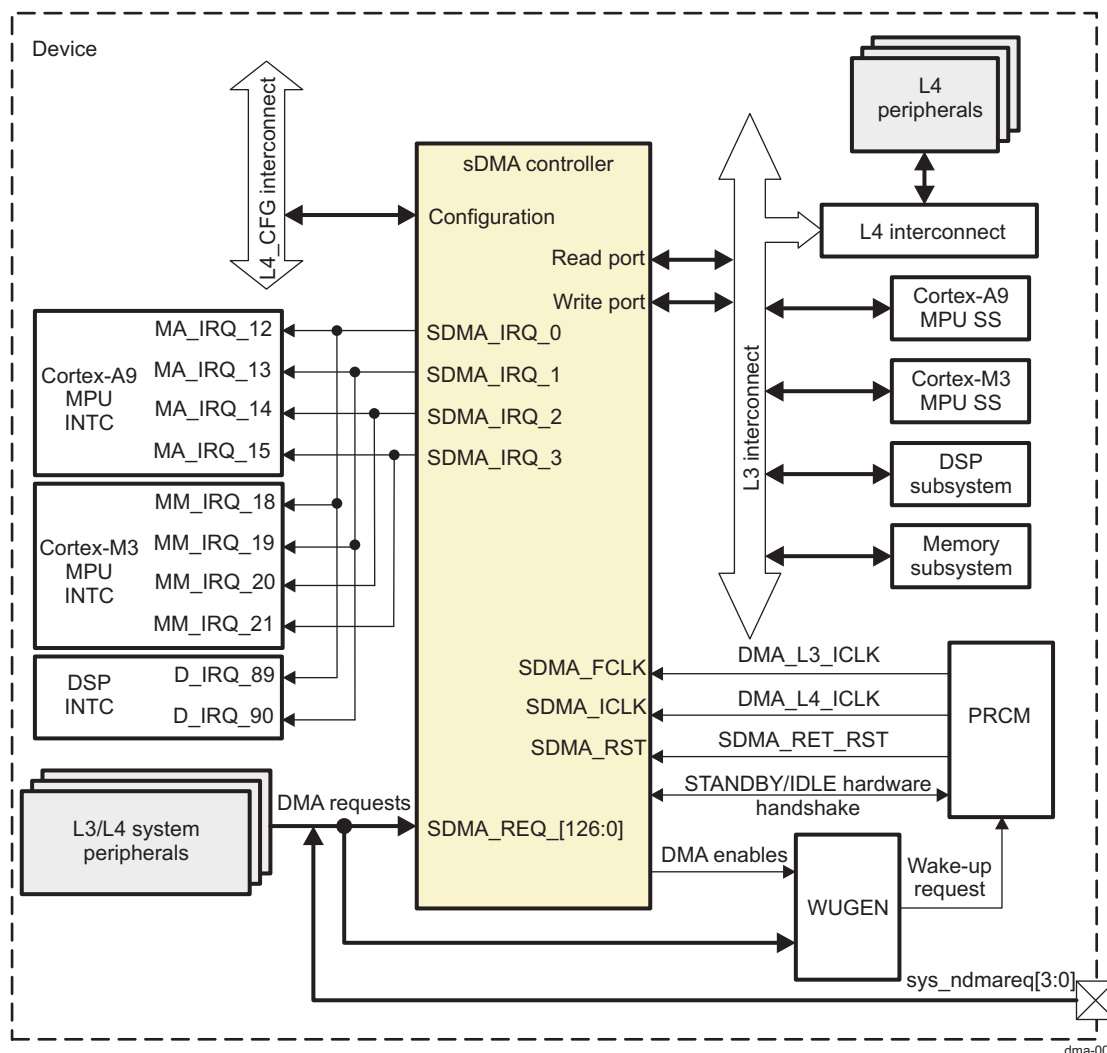

16.3 sDMA Module Integration

This section describes module integration in the device, including information about clocks, resets, and hardware requests.

Figure 16-4 shows the sDMA controller integration.

Figure 16-4. sDMA Controller Integration

NOTE: For more information about the wake-up generator (WUGEN), the STANDBY/IDLE hardware handshake, and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-2 through Table 16-4 summarize the integration of the module in the device.

Table 16-2. Integration Attributes

| Module Instance | Attributes | |
|-----------------|--------------|---------------|
| | Power Domain | Interconnect |
| sDMA | PD_CORE | L3 and L4-CFG |

Table 16-3. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| sDMA | SDMA_FCLK | DMA_L3_ICLK | PRCM | It is both a functional clock for all internal logic and for the two master read and write ports. For information about PRCM clock gating and management, see Chapter 3, Power, Reset, and Clock Management . |
| sDMA | SDMA_ICLK | DMA_L4_ICLK | PRCM | Interface clock. It supports the configuration port. For information about PRCM clock gating and management, see Chapter 3, Power, Reset, and Clock Management . |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| sDMA | SDMA_RST | SDMA_RET_RST | PRCM | Hardware reset. It initializes all internal logic of the sDMA module, all global registers and some of the per-channel registers, implemented in flip-flops. However, all remaining per-channel registers are memory-based, and, therefore, are not reset (have undefined values). Thus, when programming a channel for the first time, all bits that have undefined reset values must be configured before enabling the channel. For information about PRCM reset sources and distribution, see Chapter 3, Power, Reset, and Clock Management . |

Table 16-4. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|--------------------|-----------------------------------------------------------------------------------------------------------------|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| sDMA | SDMA_IRQ_0 | MA_IRQ_12 | Cortex-A9 MPU INTC | sDMA interrupt request 0. For information about the Cortex-A9 MPU INTC, see Section 17.3.2 . |
| | SDMA_IRQ_1 | MA_IRQ_13 | Cortex-A9 MPU INTC | sDMA interrupt request 1 |
| | SDMA_IRQ_2 | MA_IRQ_14 | Cortex-A9 MPU INTC | sDMA interrupt request 2 |
| | SDMA_IRQ_3 | MA_IRQ_15 | Cortex-A9 MPU INTC | sDMA interrupt request 3 |
| sDMA | SDMA_IRQ_0 | MM_IRQ_18 | Cortex-M3 MPU INTC | sDMA interrupt request 0. For information about the Cortex-M3 MPU INTC, see Section 17.3.3 . |
| | SDMA_IRQ_1 | MM_IRQ_19 | Cortex-M3 MPU INTC | sDMA interrupt request 1 |
| | SDMA_IRQ_2 | MM_IRQ_20 | Cortex-M3 MPU INTC | sDMA interrupt request 2 |
| | SDMA_IRQ_3 | MM_IRQ_21 | Cortex-M3 MPU INTC | sDMA interrupt request 3 |
| sDMA | SDMA_IRQ_0 | D_IRQ_89 | DSP INTC | sDMA interrupt request 0. For information about the DSP INTC, see Section 5.3.7 . |
| | SDMA_IRQ_1 | D_IRQ_90 | DSP INTC | sDMA interrupt request 1 |

NOTE: For a description of the interrupt source, see [Section 16.4.2, sDMA Controller Interrupt Requests](#).

16.3.1 DMA Requests to the sDMA Controller

Table 16-5 lists the sDMA controller request mapping.

Table 16-5. sDMA Controller Request Mapping

16.4 sDMA Functional Description

The sDMA module provides high-performance data transfers between memories and peripheral devices with low processor use. A DMA transfer is programmed through a logical DMA channel, which allows the transfer to be optimally tailored to the requirements of the application.

Figure 16-5 shows the sDMA controller top-level block diagram.

Figure 16-5. sDMA Controller Top-Level Block Diagram

dma-005

16.4.1 sDMA Controller Power Management

Table 16-6 describes power-management features available for the sDMA controller.

NOTE:

- For information about source clock gating and sleep/wake-up transitions, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).
- For a description of the EnaWakeUp, IdleMode, ClockActivity, and StandbyMode features, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 16-6. Local Power Management Features

| Feature | Registers | Description |
|------------------------|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Clock auto gating | DMA4_OCP_SYSCONFIG [0] AUTOIDLE bit | This bit allows local power optimization inside the module by gating the SDMA_ICLK clock upon the interface activity. |
| Slave idle modes | DMA4_OCP_SYSCONFIG [4:3] SIDLEMODE bit field | Force-idle, no-idle and smart-idle modes are available. |
| Clock activity | DMA4_OCP_SYSCONFIG [9:8] CLOCKACTIVITY bit field | For configuration details, see Table 16-7 . |
| Master standby modes | DMA4_OCP_SYSCONFIG [13:12] MIDLEMODE bit field | Force-standby, no-standby and smart-standby modes are available. |
| Global Wake-up Enable | N/A | Feature not available |
| Wake-up Sources Enable | N/A | Feature not available |

Table 16-7. Clock Activity Settings

| SDMA_CLOCKACTIVITY Values | Clock State When Module is in IDLE State | |
|---------------------------|------------------------------------------|-----------|
| | SDMA_ICLK | SDMA_FCLK |
| 00 | Off | Off |
| 10 | Off | On |
| 01 | On | Off |
| 11 | On | On |

CAUTION

Because the PRCM module cannot read [CLOCKACTIVITY](#) settings through hardware, software must ensure consistent programming between the [SDMA_CLOCKACTIVITY](#) and sDMA clock PRCM control bits. For a description of the [ClockActivity](#) feature, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

16.4.2 sDMA Controller Interrupt Requests

DMA4 has four interrupt lines (L_j , where $j = 0, 1, 2, 3$). Each logical channel can request an interrupt over any line. The attachment of a channel interrupt event to one of these four external lines is programmable. Software determines whether it attaches a channel interrupt to a single IRQ line or to multiple IRQ lines.

There are two different registers per interrupt line:

- The [DMA4_IRQSTATUS_Lj](#) CH_31_0_Lj field shows the status of the different sources of interrupt. If the [DMA4_IRQENABLE_Lj](#) bit is 1, channel i is the source of interrupt in line j . In contrast to the [DMA4_CSRI](#) registers, the [DMA4_IRQSTATUS_Lj](#) registers are updated regardless of the corresponding bits in the [DMA4_IRQENABLE_Lj](#) registers.
- The [DMA4_IRQENABLE_Lj](#) CH_31_0_Lj_EN field masks/unmasks the channel interrupt. If the [DMA4_IRQENABLE_Lj](#) bit is set to 0, channel interrupt i of the line j is masked.

Each logical channel can generate a number of different interrupt events when enabled (that is, set to 1) in the [DMA4_CICRI](#) register. Each status bit is updated in the [DMA4_CSRI](#) register only when the corresponding enable bit is enabled in the [DMA4_CICRI](#) register.

To determine an interrupt source when an interrupt rises on an interrupt line L_j :

- Identify the channel (LCH_i) generating the interrupt.
Read the [DMA4_IRQSTATUS_Lj.LCHi](#) (LCH_0 to LCH_{31}). If $LCH_i = 1$, channel i is the originator of the interrupt.
- Identify the interrupt event.
Read the LCH_i [DMA4_CSRI](#). For example, if the drop event (the [DMA4_CSRI](#)[1] DROP bit) is 1, there

will be a request collision.

The interrupt event status bit in the [DMA4_CSRi](#) register is immediately reset after it is written to 1.

The interrupt status bit in the [DMA4_IRQSTATUS_Lj](#) register is cleared after it is written to 1.

16.4.2.1 Interrupt Generation

The sDMA module has four interrupt request output lines, [SDMA_IRQ_0](#) to [SDMA_IRQ_3](#). One or more logical channels can be programmed to generate an interrupt request on any of these lines when any one of the maskable DMA events listed in [Table 16-8](#) occurs.

Table 16-8. Logical DMA Channel Events

| Event | Description |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| End of packet | A packet transfer completed. |
| End of block | A block transfer completed. |
| End of frame | A frame transfer completed. |
| End of super block | A super block transfer completed. |
| Half of frame | Half of the current frame transferred. |
| Start of last frame | The first element of the last frame transferred. |
| Transaction error | A transaction error is returned by the interconnect in either the read or write port. |
| Address error | An attempt was made to perform a DMA access to an address not aligned on an ES boundary. Condition to occur: if DMA4_CEN[23:0] CHANNEL_ELMNT_NBR = 0x000000 or DMA4_CFN[15:0] CHANNEL_FRAME_NBR = 0x0000 or DMA4_CSDP[1:0] DATA_TYPE = 0x3. |
| Supervisor transaction error | An error occurred, for example, when an unauthorized initiator (that is not a supervisor) tries to use a supervisor transfer. |
| Drain end | Drain is completed (DMA4_CCRi[10] WR_ACTIVE becomes 0). |
| Drop error | A drop event interrupt is generated when a DMA request is being serviced while a second one is asserted and a third one arrives before the second DMA request is serviced. |

The logical DMA channels that generate an interrupt on a particular IRQ output are specified through the [DMA4_IRQENABLE_Lj](#) register (where *j* is the IRQ number: 0, 1, 2, or 3). The events that generate an interrupt for a particular channel can be configured through the channel [DMA4_CICRi](#) register.

When an interrupt is detected, the logical DMA channel generating the event can first be identified by reading the [DMA4_IRQSTATUS_Lj](#) register. The event causing the interrupt then can be identified by reading the interrupt status via the relevant DMA channel [DMA4_CSRi](#) register.

16.4.3 Logical Channel Transfer Overview

As [Figure 16-5](#) shows, the sDMA module has one read port and one write port operating independently of each other. Buffering is provided between the read and write ports through a FIFO queue memory pool that is shared dynamically between the active logical channels.

- Logical channel synchronization

A logical channel is described as hardware-synchronized when the DMA transfers are triggered by DMA requests from a hardware device. Alternatively, a logical channel is described as nonsynchronized when the DMA transfer is triggered by software.

- Logical channel activation

A logical channel becomes active as follows:

- For hardware-synchronized transfers, when the logical channel is enabled and the hardware DMA request line is asserted
- For software-triggered (nonsynchronized) transfers, as soon as software enables the logical channel

- Logical channel transfer composition

A DMA transfer is divided automatically into a number of transactions. Depending on the logical channel context configured, the transfer size, the start address alignment, the addressing mode, and

the configured maximum burst size, each transaction can be either a single access or a burst of accesses.

- Logical channel scheduling

When several logical channels are active at the same time, schedulers manage the read and write ports. The scheduling of logical channel transfers is similar for both read and write ports. When a logical channel becomes active, it is added to the tail of a scheduling queue. If more than one logical channel becomes active at the same time, the one with the lower number is queued first. This mechanism provides a first-come, first-serve scheduling scheme between the concurrently active logical channels.

In addition, each read and write port has a high-priority queue and a low-priority queue. The priority bits (WRITE_PRIORITY and READ_PRIORITY) in the logical channel `DMA4_CCRi` register determine if a logical channel is queued as high or low priority. A software-configurable 8-bit priority counter gives weighting to the priority write queue. For every N (1 to 255) schedules from the priority write queue, one is scheduled from the regular write queue. A channel that is scheduled goes to the end of the queue after it completes its turn on the port. The relative weighting of the scheduling of the high-priority queue to the low priority queue is programmable from 1:1 to 1:256 through the DMA global channel register using the `DMA4_GCR[23:16] ARBITRATION_RATE` bit field.

NOTE: The `DMA4_GCR[23:16] ARBITRATION_RATE` field does not depend on the `DMA4_GCR[13:12] HI_THREAD_RESERVED` field. The `ARBITRATION_RATE` field depends on the `DMA4_CCRi[26] WRITE_PRIORITY` bit and the `DMA4_CCRi[6] READ_PRIORITY` bit.

- Read/write port access scheduling policy

When either the read or write port becomes available, the port access scheduler selects the next logical channel for which to perform a DMA transaction from either the high- or low-priority queue.

When the current DMA transaction (single or burst access) is complete and the full DMA transfer is not finished, the logical channel returns to the tail of the queue. Because the port access scheduling is on a per-transaction basis, a logical channel can be queued repeatedly this way several times during its block transfer.

The sDMA module can have up to four outstanding read transactions and two outstanding write transactions in the system interconnect; four read and two write thread IDs exist. For an arbitration cycle to occur, these two conditions must be met:

- At least one channel is requesting.
- At least one free thread ID is available.

On an arbitration cycle, the scheduler grants the highest priority channel that has an active request, allocates the thread ID, and tags this thread as busy. At a given time, a channel cannot be allocated for more than one thread ID.

NOTE: If more than one channel is active, each channel is given a thread ID for the current service only, not for the whole channel transfer.

When only one channel is enabled, only one thread is allocated for the channel. In such a situation the channel can have maximum of four outstanding commands (without getting the responses) without rescheduling the channel at the end of each transaction. Each command can be either single access (8-bit, 16-bit or 32-bit) or burst access (2 x M, 4 x M, 8 x M or 16 x M, where M can be 8-bit, 16-bit or 32-bit).

When nonburst alignment is at the beginning of the transfer, the channel is rescheduled for each smaller access until burst-aligned. When the end of the transfer is not burst-aligned, the channel is rescheduled for each of the remaining smaller accesses.

For a logical channel transfer completion, when the last access is written to the destination, the logical channel becomes inactive. If enabled, an interrupt request is generated (see [Section 16.4.2.1, Interrupt Generation](#)).

16.4.4 FIFO Queue Memory Pool

A FIFO queue memory pool provides buffering between the read and write ports. The hardware allocates the space dynamically to a number of FIFO queues, and each queue is associated with an active logical channel.

To avoid a memory pool overflow, if there are fewer entries in the FIFO queue memory pool than are required for the maximum configured source burst size of the next logical channel to be scheduled, the logical channel is returned to the tail of the queue, and the port access scheduler continues to search the queue until it finds a logical channel that can be scheduled.

The maximum FIFO depth that can be allocated to each individual logical channel can be limited globally through the [DMA4_GCR\[7:0\] MAX_CHANNEL_FIFO_DEPTH](#) bit field. This value should be configured to allow a fair allocation of the memory pool between the active channels.

A logical channel is scheduled if it has not yet reached its allocation limit, even if the access to be performed will exceed this limit. This means that the effective number of entries used by a particular logical channel is limited to the configured maximum entries per channel + channel maximum configured burst size (in words) - 1.

16.4.5 Addressing Modes

A DMA transfer block consists of a number of frames (FN). Each frame consists of a number of elements (EN), and each element can have a size of 8, 16, or 32 bits (ES), as follows:

$$\text{transfer block size} = \text{FN} \times \text{EN} \times \text{ES}$$

The FN, EN, and ES are common for both the source and destination. However, the way in which the data is represented (addressing profile/mode) is independently programmable for the source and destination devices, using one of these four addressing modes:

- Constant: The address remains the same for consecutive element accesses.
- Post-increment: The address increases by the ES, even across consecutive frames.
- Single-index: The address increases by the ES plus the element index (EI) value minus 1 (even across consecutive frames).
- Double-index: The address increases by the ES plus the EI value minus 1 within a frame. When a full frame is transferred, the address increases by the ES plus the frame index (FI) value minus 1.

The ES, EI, and FI values are expressed in bytes. The EI and FI values can be positive or negative.

When calculating the EI and FI values, it is critical to note that, after an element is accessed, the logical channel address pointer equals the address of the last byte (highest address) of the accessed element. The correct value for the EI or FI should be such that, when added to the logical channel address pointer, results in the address of the first byte (lowest address) of the next element to be accessed.

The EI and FI values must be configured so that the address of each element in the transfer is aligned on an ES boundary.

Consequently, the single-index addressing mode with EI = 1 or double-index addressing mode with EI = 1 and FI = 1 is equivalent to post-increment addressing.

NOTE: The source and destination start addresses must also be aligned on an ES boundary.

When the address of an element to be accessed is not aligned on an ES boundary, the transfer is stopped and a misaligned address error interrupt occurs, if enabled (see [Section 16.4.2.1, Interrupt Generation](#)).

The [DMA4_CFNi](#) register configures the FN in a block.

The [DMA4_CENi](#) register configures the EN.

The [DMA4_CSDPi](#) register configures the ES.

The [DMA4_CSSAi](#) and [DMA4_CDSAi](#) registers configure the source and destination start addresses.

The [DMA4_CCRi](#) register configures the source and destination addressing modes.

The [DMA4_CSEIi](#), [DMA4_CSFIi](#), [DMA4_CDEIi](#), and [DMA4_CDFIi](#) registers configure the source EI, source FI, destination EI, and destination FI, respectively.

The addressing profiles are expressed as equations as follows:

Equation 1. Constant addressing:

$$A(n + 1) = A(n)$$

NOTE: Constant addressing mode with DMA4 to/from DDR memory is not supported on the OMAP4430 device.

To fill DDR memory with a single value, the constant fill feature of DMA4 must be used instead of a constant addressing mode transfer.

Equation 2. Post-increment addressing:

$$A(n + 1) = A(n) + ES$$

Equation 3. Single-indexed addressing:

$$A(n + 1) = A(n) + ES + (EI - 1)$$

Equation 4. Double-indexed addressing:

When not at the end of a frame or transfer (that is, when the element counter $\neq 0$):

$$A(n + 1) = A(n) + ES + (EI - 1)$$

When at the end of a frame but not at the end of the transfer (that is, when the element counter = 0 and the frame counter $\neq 0$):

$$A(n + 1) = A(n) + ES + (FI - 1)$$

Calculate the element and frame index as follows:

Equation 5. Element index

$$EI = [(Stride - EI - 1) * ES] + 1$$

Equation 6. Frame index

$$FI = [(Stride - FI - 1) * ES] + 1$$

where:

$A(n)$: Byte address of the element n within the transfer.

ES is in bytes, ES{1, 2, 4}.

EI is in bytes, specified in a configuration register, 32768 EI 32767.

Stride EI: The difference in the number of elements between the start of the current element n to the start of next element, $n+1$.

Element counter: A counter that is (re)initiated with the number of elements per frame or per transfer. Decreased by 1 for each element transferred. The initial value is configured in the register DMA channel element number, [DMA4_CENi](#).

FI is in bytes, specified in a configuration register, 2147483648 FI 2147483647.

Stride FI: The difference in the number of elements between the start of the last element of the current frame and the beginning of the first element of the next frame.

Frame counter: A counter that is (re)initiated with the FN per transfer. Decreased by 1 for each frame transferred. The initial value is configured in the register DMA channel frame number, [DMA4_CFNi](#).

[Figure 16-6](#) shows how a stride EI and FI are defined. When handling complex configurations, using strides can make it easier to calculate EI and FI because you can calculate in elements instead of bytes. (This approach is used in the 90-degree clockwise image rotation example shown in [Figure 16-10](#).) The double-index addressing example shown in [Figure 16-6](#) uses ES = 4, EN = 2, EI = 5, FI = 5, and FN = 2.

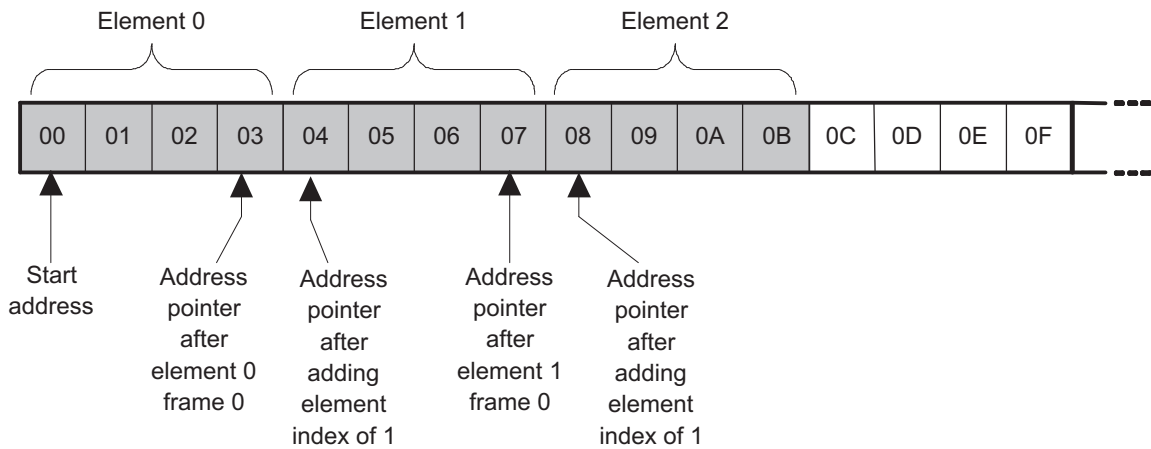

[Figure 16-6](#) through [Figure 16-9](#) show examples of addressing mode configurations. [Table 16-9](#) lists parameter values for the examples.

Figure 16-6. Example Showing Double-Index Addressing, Elements, Frames, and Strides

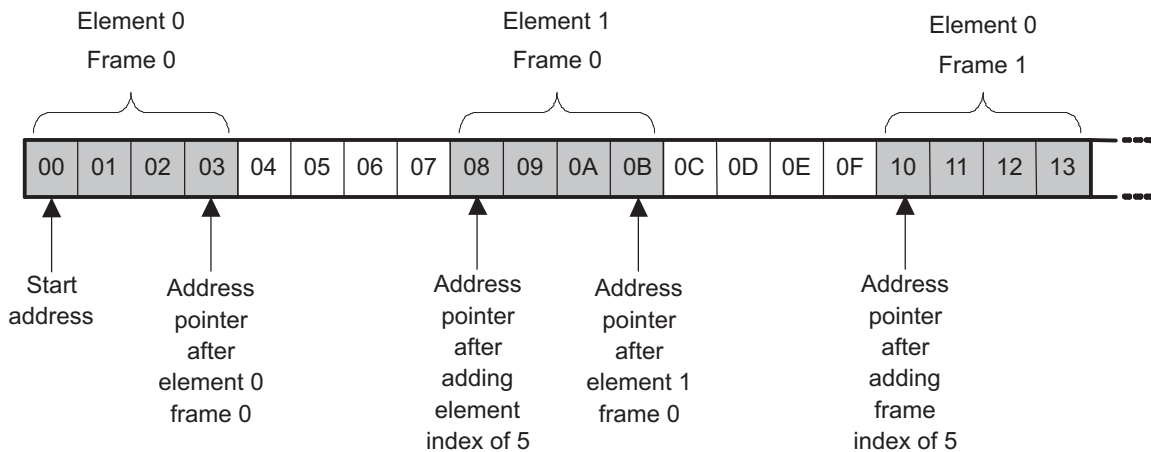

dma-011

Figure 16-7. Addressing Mode Example (a)

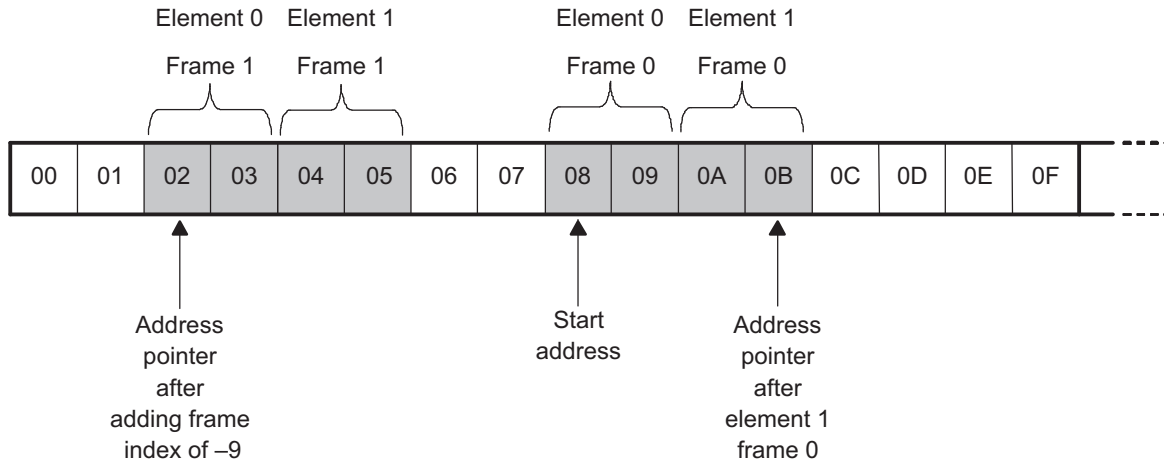

dma-010

Figure 16-8. Addressing Mode Example (b)

dma-009

Figure 16-9. Addressing Mode Example (c)

dma-008

Table 16-9. Parameter Values for Addressing Mode Examples (a), (b), and (c)

| Parameter | Example (a) | Example (b) | Example (c) |
|-----------------|-------------------------------------|--------------|--------------|
| Addressing mode | Single index (or post-increment) | Double index | Double index |
| Start address | 0 | 0 | 8 |
| ES | 4 (32-bit) | 4 (32-bit) | 2 (16-bit) |
| EN | 3 | 2 | 2 |
| EI | 1 | 5 | 1 |
| FN | 1 | 2 | 2 |
| Frame index | N/A | 5 | -9 |

Double indexing can occur either on source (read) or destination (write). Equations for rotation of xx degrees on destination are obtained by taking equations for rotation of $(360 - xx)$ degrees on source, and swapping the width (x) and height (y) of the image in them. The opposite is also true. Table 16-10 lists the equations for 90-, 180-, and 270-degree rotations.

Table 16-10. Equations for Rotation

| | | 90 Rotation | 180 Rotation | 270 Rotation |
|----------------------------------------|--------------|----------------------|--------------|----------------------|
| Double indexing on destination (write) | Base address | $ES*(y-1)$ | $ES*(x*y-1)$ | $ES*y*(x-1)$ |
| | EI | $ES*(y-1) + 1$ | $1-2*ES$ | $1-ES*(y + 1)$ |
| | FI | $1 ES*[(x-1)*y + 2]$ | $1-2*ES$ | $1+ES*(x-1)*y$ |
| Double indexing on source (read) | Base address | $ES*x*(y-1)$ | $ES*(x*y-1)$ | $ES*(x-1)$ |
| | EI | $1-ES*(x + 1)$ | $1-2*ES$ | $ES*(x-1) + 1$ |
| | FI | $1+ES*(y-1)*x$ | $1-2*ES$ | $1 ES*[(y-1)*x + 2]$ |

Table 16-11 and Figure 16-10 show the configuration required to perform a 90-degree clockwise rotation of a 240 x 160 pixel, 32-bit image. The EI, frame size, and FI values are configured so that the image is rotated line by line starting at the left end of the top line.

NOTE: The FI value for the destination is negative so that the first pixel of each subsequent line of the source image is written to the correct location at the destination.

Equation 5 and Equation 6 calculate the destination, FI and EI. The example assumes that the image lines are stored at consecutive addresses in memory, meaning that both EI and FI on the source side are 1.

Rotations:

Section 16.5.7, *90-Degree Clockwise Image Rotation*, describes how to program an example of a 90-degree clockwise image rotation.

Observe that:

- One pixel = one element
- One line = one DMA frame
- Pixel size = element size = ES

Table 16-11. Example Parameter Values for a 90-Degree Clockwise Image Rotation

| Parameter | Source Value | Destination Value |
|-----------------------------|------------------------------|-------------------------------------|
| Bits per pixel | 32 | 32 |
| ES | 4 | 4 |
| Image width | SW | SH |
| Image height | SH | SW |
| Stride elements (stride EI) | 1 element | SH |
| Stride frames (stride FI) | 1 element | -[(SW-1)*SH + 1] = 38,241 elements |
| Start address | 0x100000 | 0x200000 + (SH - 1) * ES = 0x20027C |
| EN | SW | SW |
| EI | [(Stride EI 1) * ES] + 1 = 1 | [(Stride EI 1) * ES] + 1 = 637 |
| FN | SH | SH |
| FI | [(Stride FI 1) * ES] + 1 = 1 | [(Stride FI 1) * ES] + 1 = 152,967 |

Figure 16-10. Example of a 90-Degree Clockwise Image Rotation

16.4.6 Packed Accesses

To pack data means to group data to match the bus size, thus optimizing a transfer. When the logical channel ES is less than the DMA module read/write port size, and the addressing profile supports it (post-increment mode or single- or double-index mode with EI = 1), the number of elements to transfer in each read/write port access can be maximized by specifying that the source or destination is packed through the channel DMA4_CSDPi register. Thus:

- For a read/write port size of 32 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (four elements per access) and 16 bits (two elements per access).

- For a read/write port size of 64 bits, the source or destination can be configured as packed for transfer ESs of 8 bits (eight elements per access), 16 bits (four elements per access), and 32 bits (two elements per access).

Depending on the start address and transfer length, the first or last packed access can be only partially filled. This is indicated to the source or destination using the byte-enable signals.

16.4.7 Burst Transactions

Transfer performance can be improved so that the source or destination and addressing profile supports it. This can be achieved by configuring the logical channel to perform burst transactions consisting of multiple instead of single accesses. The channel can be programmed to use burst sizes equal to 16, 32, or 64 bytes through the [DMA4_CSDPi](#) register, with the read burst size programmable independently of the write burst size. Typically, the optimal burst size is 64 bytes (16 accesses for a 32-bit read/write port size or 8 accesses for a 64-bit read/write port size).

To obtain the maximum benefit from burst transactions, the source and destination start addresses must be aligned with the burst size. If this is not the case, the start of the transfer can consist of a number of smaller (single or burst) transactions until the first burst size boundary is reached.

Similarly, if the end of the transfer is not aligned on a burst size boundary, the final part of the transfer can consist of a number of smaller transactions.

NOTE: If post-incrementing is used, data must be packed to DMA data-port width, to use burst.

16.4.8 Endianism Conversion

The source and destination are each specified as little-endian or big-endian through the [DMA4_CSDPi](#) register for the particular logical channel. If the endianism of the source and destination differ, and if the logical channel ES is less than the sDMA module read/write port size, an endianism conversion is applied to the data before it is written to the destination.

When transferring data between a source and a destination with different endianism, it is important to specify an ES that equals the type of data being transferred to preserve the correct data image at the destination.

In the system, endianism conversion can be performed in more than one place. It is possible to instruct the source and/or destination to lock the endianism (that is, to not perform a conversion) through the logical DMA channel [DMA4_CSDPi](#) register.

NOTE: Because the device is little-endian by construction, the sDMA endianism registers must never be set to big-endian.

If sDMA is used to execute endian conversion by setting the source and destination to different endianism values, it is important to consider that the L3 interconnect also executes endian conversion if the sDMA and the source or destination have a different data bus width.

16.4.9 Transfer Synchronization

A logical channel can be programmed for either software-triggered or hardware synchronized transfers.

16.4.9.1 Software Synchronization

A transfer is software-triggered when the logical channel is set up and started by software. To specify a software-triggered transfer, set the channel DMA [DMA4_CCRi\[4:0\]](#) and [DMA4_CCRi\[20:19\]](#) bit fields to 0. The transfer starts as soon as the DMA [DMA4_CCRi\[7\]](#) bit is set (when it enters the scheduling process).

16.4.9.2 Hardware Synchronization

A transfer is hardware-synchronized if the logical channel activation is driven by hardware requests from the source or destination target. A hardware-synchronized transfer is specified by configuring the DMA request line number in the channel `DMA4_CCRi` register to a value that corresponds to the DMA request line from the source or destination that generates the DMA requests. The DMA request numbers to be configured are specified in the DMA request mapping (see [Table 16-8](#)).

Specify the DMA request number in the `DMA4_CCRi[4:0]` SYNCHRO_CONTROL and `DMA4_CCRi[20:19]` SYNCHRO_CONTROL_UPPER bit fields. After the `DMA4_CCRi[7]` ENABLE bit is set, the logical channel becomes enabled but not activated (it does not enter the scheduling process), which means that channel registers are not updated until the first DMA request is received.

NOTE: The channel synchronization control registers are 1-based. For example, to enable the `S_DMA_1` request, the `DMA4_CCRi[4:0]` SYNCHRO_CONTROL bit field must be set to `0x2` (DMA request number + 1).

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared among several chained logical channels.

For hardware synchronization, the amount of data to be transferred for each assertion of the DMA request line is configured through the frame synchronization (FS) and block synchronization (BS) bits in the logical channel `DMA4_CCRi` register and the `DMA4_CCRi[5]` FS and `DMA4_CCRi[18]` BS bits, respectively.

The amount of data can be any of the following:

- A single element transfer: A complete element defined by data type. For example, 8/16/32 bits are transferred in response to a DMA request.
- A full frame: A complete frame of several elements is transferred in response to a DMA request.
- A full block (a full channel transfer): A complete block of several frames is transferred in response to a DMA request.
- A full packet (a full channel transfer): A complete packet of several elements is transferred in response to a DMA request.

Packets allow the size of each part of the full DMA transfer to be configured independently of the organization of the data to be transferred (typically a number of elements). This can be useful when the source or destination has a buffer (such as a FIFO queue) with a size unrelated to the frame size of the transfer. The packet size then can be set to the size of the buffer.

Packet transfer must be used only where the source or destination is addressed in constant addressing mode, because FI registers are reused to specify the packet size.

To support the burst mode, the logical channel must also be configured in target-port packed access mode.

The packet size is configured based on the `DMA4_CCRi[24]` SEL_SRC_DST_SYNC bit through either the channel `DMA4_CDFIi` register (source synchronized) or the `DMA4_CSFIi` register (destination synchronized).

When the logical channel transfer block is not an exact multiple of the packet size, the final packet consists of the remaining elements in the transfer, using burst or single accesses to complete the block transfer.

The maximum transfer size, regardless of the packet size, is always as follows:

$$\text{Block_size} = \text{Number_of_Frame_in_Block} * \text{Number_of_Element_in_Frame} * \text{Element_Size}$$

- Synchronized at the source

The DMA module optimizes the transfer with respect to the number and size of burst transactions for the given source and destination addressing profiles and configured maximum burst sizes. When writing to the destination is slower than reading from the source, data is buffered in the channel FIFO queue. If the transfer is packet-synchronized at the source, the end-of-packet interrupt is disabled (see

Section 16.4.13, Reprogramming an Active Channel).

For a source synchronized transfer, buffering can be enabled or disabled by setting the `DMA4_CCRi[25] BUFFERING_DISABLE` bit. For a packet source synchronization with buffering disabled and the packed/burst across the packet boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the packet transfer size. However, for a packet source synchronized transfer with buffering enabled and with the packed/burst across the packet boundary, the DMA module waits for the next DMA request(s) to read enough data to issue an atomic packed/burst write transaction (assuming that the address is packed/burst aligned).

NOTE: Buffering is not performed between frames, even if it is enabled. If the packed/burst is across the frame boundary, the last packed/burst write transaction is split in optimized smaller accesses to complete the frame transfer size.

- Synchronized at the destination

The performance of a hardware-synchronized transfer can be improved by using the prefetch mode, enabled through the channel `DMA4_CCRi[23] PREFETCH` bit. Data is prefetched on the read port side before the DMA request received and buffered in the FIFO queue. Up to a full transfer block can be prefetched, although this can be limited by the specified maximum channel FIFO queue depth (see [Section 16.4.4, FIFO Queue Memory Pool](#)).

Buffering disable is not allowed for a destination-synchronized transfer.

NOTE: Behavior is undefined when prefetch is enabled and a transfer is synchronized to the source.

Regardless of whether buffering is enabled, the last transaction in the frame or in the block is write nonposted (WNP) even if the write mode is specified as write last nonposted (WLNP; the `DMA4_CSDPi[17:16] WRITE_MODE` bit field = 0x2). However, in a packet synchronization mode, the last transaction of each packet in the transfer is WNP only if the buffering disable is on (even if the write mode is specified as WLNP).

Regardless of whether buffering is enabled, the packet interrupt is not generated in the packet source synchronized mode.

CAUTION

The `DMA4_CCRi[25] BUFFERING_DISABLE` bit must be filled with an allowed value, as specified in [Table 16-12](#).

Table 16-12. Buffering Disable

| | BUFFERING_DISABLE (0: Buffering enable, 1: Buffering disable) | |
|--------------------------|-------------------------------------------------------------------------|-------------|
| Destination synchronized | 0 | Allowed |
| | 1 | Not allowed |
| Source synchronized | 0 | Allowed |
| | 1 | Allowed |

- Synchronized transfer monitoring using CDAC (`DMA4_CDACi`):
Context is restored only when the channel becomes active on a DMA request (not at software enable). The channel is software-enabled first, and then a DMA request is asserted followed by the first context restore.
The CDAC register is writable; thus, the CDAC can be initialized to monitor the transfer and determine whether the transfer is started (for more information, see [Section 16.5.4, Synchronized Transfer Monitoring Using CDAC](#)).

NOTE: For 16-bit transactions, start reading from or writing to the LSByte first to enable the register update. This is not an issue for 32-bit read-write transactions.

16.4.10 Thread Budget Allocation

When several concurrent channels are latency critical and hardware synchronized, a specific latency cannot be ensured until the target is served. This situation occurs when the number of concurrent channels is greater than the number of available threads.

NOTE: Four threads are available on the read port, and two threads are available on the write port.

For a hardware-synchronized transfer (memory to peripheral), a minimum bandwidth for a latency-critical transfer must be ensured to avoid collisions between two hardware requests.

Because it is latency critical, the software user is responsible for the following:

- Programming the synchronized channel as a high-priority channel
- Reserving one or several threads for high-priority channels

The proposed implementation is as follows (see [Section 16.5.5, Concurrent Software and Hardware Synchronization](#)):

Prevent the regular channel queue from exceeding more than a programmable (3, 2, or 1) number of threads on the read port and no more than one thread on the write port. This number can be set in the global register `DMA4_GCR[13:12]`.

The thread reservation is programmable for maximum use of thread resources for concurrent, low-priority channel transfer. Programmability can also allow a partial throughput control by limiting in software the number of concurrent outstanding requests that break the pipelining.

Depending on the `DMA4_GCR [13:12]` value, the following threadID on the read/write ports are allocated for a high-priority channel:

Read port priority thread reservation:

- `DMA4_GCR[13:12] = 0x0` => No ThreadID is reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x1` => Read ThreadID 0 is reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x2` => Read ThreadID 0 and Read ThreadID 1 are reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x3` => Read ThreadID 0, Read ThreadID 1, and Read ThreadID 2 are reserved for high-priority channels.

Write port priority thread reservation:

- `DMA4_GCR[13:12] = 0x0` => No ThreadID is reserved for high-priority channels
- `DMA4_GCR[13:12] = 0x1` => Write ThreadID 0 is reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x2` => Write ThreadID 0 is reserved for high-priority channels.
- `DMA4_GCR[13:12] = 0x3` => Write ThreadID 0 is reserved for high-priority channels.

Regardless of whether the enabled channels are high priority, only the setting of the `DMA4_GCR[13:12]` value forces the thread reservation to these values. Set the appropriate value to avoid losing threads using only regular channels.

To have an independent read and write priority context, a per-channel bit (`DMA4_CCRI[26]`) is added for write priority, and the previous priority bit becomes read priority bit (`DMA4_CCRI[6]`).

NOTE: The device has one priority bit per logical channel, not one priority bit per port.

16.4.11 FIFO Budget Allocation

To avoid fully occupying the FIFO with a high-priority transfer while low-priority channels wait in the arbitration queue, two separate FIFO budgets are specified: one for high-priority channels and one for low-priority channels. This is defined in the [DMA4_GCR](#) register, allowing the user to share the FIFO budget between the low- and high-priority channels. The amount of the FIFO allocated by the low- and high-priority channels is fixed by the value set in the [DMA4_GCR\[15:14\] HI_LO_FIFO_BUDGET](#) field. The maximum channel FIFO depth is limited by the [HI_LO_FIFO_BUDGET](#) field as follows:

If the channel is low priority:

- When [HI_LO_FIFO_BUDGET](#) = 0x1, then low priority cannot exceed 75 percent of the total FIFO.
- When [HI_LO_FIFO_BUDGET](#) = 0x2, then low priority cannot exceed 25 percent of the total FIFO.
- When [HI_LO_FIFO_BUDGET](#) = 0x3, then low priority cannot exceed 50 percent of the total FIFO.

If channel is high priority

- When [HI_LO_FIFO_BUDGET](#) = 0x1, then high priority cannot exceed 25 percent of the total FIFO.
- When [HI_LO_FIFO_BUDGET](#) = 0x2, then high priority cannot exceed 75 percent of the total FIFO.
- When [HI_LO_FIFO_BUDGET](#) = 0x3, then high priority cannot exceed 50 percent of the total FIFO.

The user is responsible for performing the following equation:

- For a high-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of High Channel} = < \text{High Budget FIFO}$
- For a low-priority channel: $(\text{Per_Channel_Maximum FIFO Depth} + 1) \times \text{Number of Low Channel} = < \text{Low Budget FIFO}$

NOTE: Ensure that *Number of High Channel* means *Number of Active High-Priority Channel* and that *Number of Low Channel* means *Number of Active Low-Priority Channel*.

16.4.12 Chained Logical Channel Transfers

Chaining multiple logical channels permits transfers consisting of multiple parts to be executed without repeated software intervention. This results in better performance than the alternative of software setting up and starting each transfer separately. Each part of a chained transfer can have the data addressed in a different manner that permits the programming of a variety of complex transfers. For example:

- Interlaced video data with one logical channel configured to transfer the even lines and another logical channel configured to transfer the odd lines
- Protocol headers with a separate DMA4 channel configured to transfer each field in the header

Channels can be chained through each channel [DMA4_CLNK_CTRLi](#) register. When the transfer for the first channel completes, the next channel in the chain is enabled. The number of channels in the chain that are configured for hardware-synchronized transfers is flexible (although typically it might be all, none, or just the first one). The DMA request line number should be set to 0 to specify that any or all of the channels in a chain are software-triggered or nonsynchronized.

The last channel in a chain can be chained to the first channel to create a continuously looping chain. The continuously looping transfer can be stopped on the fly at a specific channel by disabling the [DMA4_CLNK_CTRLi\[15\] ENABLE_LNK](#) bit. The looping transfer stops after the specified channel transfer is complete.

NOTE: DMA Request Line

A DMA request line must not be shared between concurrently enabled DMA channels. However, a DMA request line can be shared between several chained logical channels.

For more information on the programming model, see [Section 16.5](#), *sDMA Basic Programming Model*.

16.4.13 Reprogramming an Active Channel

A currently active logical DMA channel can be disabled through the `DMA4_CCRi[7]` ENABLE bit. When an ongoing transaction is complete and the read-active and write-active bits in the `DMA4_CCRi` register (`DMA4_CCRi[9]` RD_ACTIVE and `DMA4_CCRi[10]` WR_ACTIVE) are reset, the channel can be reprogrammed for a new transfer.

16.4.14 Packet Synchronization

A packet transfer notion is related to the behavior of some peripherals, which have certain buffering capability and requires to transfer the buffer content once an element number threshold is reached (a hardware DMA request is generated). To associate a frame synchronization to each DMA request is possible, but this limits the maximum transfer size. Indeed the maximum transfer size is proportional to the FIFO depth of the peripheral:

$$\text{maximum_transfer_size} = \text{peripheral_FIFO_depth} \times \text{number_of_frame_in_block}$$

The packet synchronization allows to dissociate the transfer size from the FIFO depth of the peripheral. Only Constant addressing mode is allowed on a read port or a write port if source target or destination target is packet synchronized respectively.

Example:

Consider a camera interface with a FIFO_depth of 128 words and a FIFO_element_number_threshold of 128, and a picture to transfer with a size 320 lines by 240 columns. If frame synchronization is associated with each DMA request then the maximum transfer size that can be performed is 128×2^{16} words. In this case, a frame is 128-word long, which does not fit the size of a line, and it is not possible to generate an interrupt at the end of line. However, by introducing the packet transfer notion, which is related to the peripheral FIFO behavior/structure, the maximum transfer size ($\text{maximum_transfer_size} = 2^{24} \times 2^{16}$ words) is independent of both peripheral_FIFO_depth and FIFO_element_number_threshold. This allows a long-enough transfer within one channel context and rotation operation on a large image format.

The main features of DMA Packet transfer are as follows:

- DMA Packet_Data_Size for each DMA Request: the Peripheral_element_number_threshold (the number of elements in a packet) shares the `DMA4_CSFIi` and `DMA4_CDFIi` configuration registers. If the peripheral is the source target, the addressing mode is constant, and the `DMA4_CSFIi[15:0]` bit field is used to specify the packet data size in the `DMA4_CSFIi` register. The user must set the `DMA4_CCRi[24]` SEL_SRC_DST_SYNC bit to 1. If the peripheral is the destination target, the addressing mode is constant, the `DMA4_CDFIi[15:0]`, is used to specify the packet data size (PKT_ELNT_NBR), and the bit field [31:16] is unused. To specify the packet data size in the `DMA4_CDFIi` register, the user must set the `DMA4_CCRi[24]` SEL_SRC_DST_SYNC bit to 0.

NOTE: The packet size can be a submultiple or non-submultiple of a frame size. If DMA Packet_Data_Size is aligned on the DMA channel block data size boundary, then DMA transfers the last data in the channel block boundary, and stops at the block boundary for the last packet DMA Request. If the Packet_Data_size is not aligned on the block boundary, the remaining data smaller than a packet size are transferred using burst or single accesses to complete the block.

- DMA Packet_Data_Transfer does not affect DMA channel capabilities in term of packing and bursting. The Packet synchronization mode is active when `DMA4_CCRi[5]` FS = `DMA4_CCRi[18]` BS = 1. Then
 - if `DMA4_CCRi[24]` SEL_SRC_DST_SYNC=0, the `DMA4_CDFIi[15:0]` bit field gives the number of elements in the packet and the `DMA4_CDFIi[31:16]` bit field is unused for the packet size.
 - if `DMA4_CCRi[24]` SEL_SRC_DST_SYNC=1, the `DMA4_CSFIi[15:0]` bit field gives the number of element in the packet and the `DMA4_CSFIi[31:16]` bit field is unused for the packet size.

NOTE: The maximum transfer size, regardless of the packet size, is always:
 $\text{Block_size} = \text{Number_of_Frame_in_Block} \times \text{Number_of_Element_in_Frame} \times \text{Element_Size}$.

If DMA channel packet/burst access is across the packet boundary, the DMA hardware automatically splits this packing/burst access into multiple smaller accesses that are aligned on the packet boundary. Otherwise, the DMA transfers data as a usual packing/burst access.

16.4.15 Graphics Acceleration Support

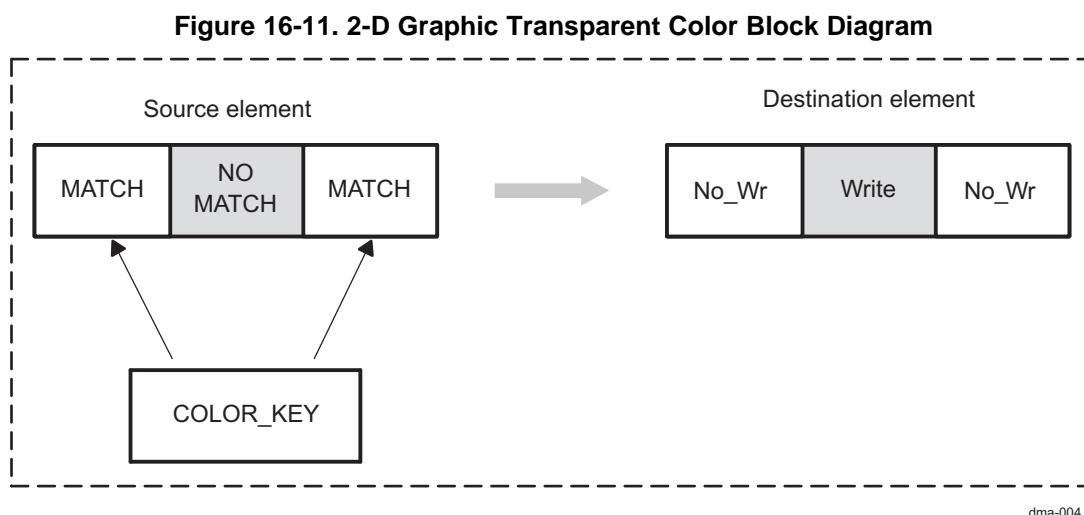

The sDMA supports two graphic acceleration features:

- Transparent copy
- Constant fill

Only one of these features can be enabled at a time through the [DMA4_CCRi](#) register for the particular logical DMA channel.

The transparent copy feature enables specification of a particular color through the [DMA4_COLORi](#) register, so that when it is recognized in the data from the source, it is not copied to the corresponding location in the destination, but instead leaves the data in the corresponding location in the destination as it is.

Figure 16-11 shows the 2-D graphic transparent color block diagram.

The constant fill feature provides the ability to specify a particular color through the [DMA4_COLORi](#) register for every specified location in the destination. In this case, the transfer consists only of writing to the destination without reading from a source.

Both features support 8 bpp (bits per pixel), 16 bpp, and 24 bpp, depending on what is specified as the DMA transfer ES via the [DMA4_CSDPi](#) register. An ES of 32 bits corresponds to 24 bpp. During a 32-bit (24 bpp) transfer, the 8 most-significant bits (MSB) ([31:24]) are 0. Both features are compatible with packed and burst transactions.

16.4.16 Supervisor Modes

A logical DMA channel can be configured to operate in supervisor mode through the [DMA4_CCRi](#)[22] SUPERVISOR bit. This must be done using supervisor access. Once a channel is configured in supervisor mode, the channel configuration is protected from nonsupervisor accesses. All DMA transactions on a supervisor channel are supervisor transactions.

16.4.17 Posted and Nonposted Writes

A logical channel can be configured in its [DMA4_CSDPi](#)[17:16] bits to use one of three write access handshake modes for the destination:

- Nonposted write: Each write must complete before transfer can continue or complete.
- Posted write: Transfer continues without waiting for each write to complete (might improve performance with slow devices).
- Posted with final write nonposted: Transfer continues without waiting for each write to complete, but final write is completed before transfer can complete.

16.4.18 *Disabling a Channel During Transfer*

When a channel is disabled during a transfer, the channel undergoes an abort, unless it is hardware source synchronized with buffering enabled ([DMA4_CCRi\[25\] BUFFERING_DISABLE = 0](#)). If this is the case, the FIFO is drained to prevent the loss of data. See [Section 16.4.19, FIFO Draining Mechanism](#), for details about this feature.

16.4.19 *FIFO Draining Mechanism*

When a source synchronized channel is disabled during a transfer, then the current hardware request (element/packet/frame/block) service is completed and the channel [DMA4_CCRi\[9\] RD_ACTIVE](#) bit is set to 0, which means the channel is not active on the read port. The remaining data in the corresponding disabled channel FIFO is drained onto the write port and transferred to the programmed destination as in normal transfer.

At the end of the draining the [DMA4_CCRi\[10\] WR_ACTIVE](#) bit is set to 0 (channel is no longer active on the write port) and if the [DMA4_CICRI\[12\] DRAIN_END_IE](#) is set to 1, the [DMA4_CSRI\[12\] DRAIN_END](#) status bit is updated and an interrupt is generated.

Once a channel is disabled during a transfer, it must wait for [DMA4_CCRi\[9\] RD_ACTIVE](#) and [DMA4_CCRi\[10\] WR_ACTIVE](#) to become 0 before being reenabled for a new transfer. The FIFO drain for a channel occurs only in the following cases:

- If the channel is a source synchronized channel and [DMA4_CCRi\[25\] BUFFERING_DISABLE = 0](#) and
- If the channel is not a solid fill channel and
- If the channel is not a transparent and copy channel and
- If the channel is a hardware, synchronized channel

NOTE: For a self-linked or chain-linked channel, the user must disable the [DMA4_CLNK_CTRLi\[15\] ENABLE_LINK](#) bit before disabling the channel.

In all other cases, the channel undergoes an abort.

16.4.20 *Linked List*

16.4.20.1 *Overview*

The sDMA supports the logical transfer descriptor loader feature. A transfer descriptor represents a set of values that maps to a set of logical channel configuration registers.

A logical channel transfer descriptor can be loaded by DMA from memories, and then successive transfer descriptors can be autonomously loaded based on a linked-list scheme. This enables DMA4 scatter gather transfers with minimum MPU support by removing successive channel configuration processing and associated interrupt handling overheads. It also optimizes DMA4 channel resources by enabling efficient transfer serialization on a single logical channel versus concurrent (multiple) logical channel use.

Different types of transfer descriptors are supported (full or partial logical channel configuration registers are set). This optimizes the memory size required for storing a long linked list, because parameter changes are limited to only a few logical channel configuration registers.

16.4.20.2 Link-List Transfer Profile

A linked-list transfer can be seen as a super-block transfer (where the block is composed of FN frames and each frame includes EN elements). The block size (FN x EN x ES) can be changed in the linked list by loading an updated transfer descriptor.

The end of the super block is signaled in the last descriptor associated with the last block. Generally, for a given link-list transfer, the logical channel is set at the beginning of the transfer and the logical channel configurations for the subsequent blocks are slightly changed. Thus, the descriptor can be limited to an update of only few parameters, such as FN or EN. This assumes that the content of unmodified registers is preserved when a new descriptor is loaded.

A transfer descriptor is composed of a set of channel configuration register values with the addition of the next-descriptor pointer register ([DMA4_CNDPi](#)) and a channel-descriptor parameter register ([DMA4_CDPi](#)). The next-descriptor pointer is the 32-bit address pointer from where the next transfer descriptor is to be loaded. The next-descriptor pointer is mapped depending on the descriptor type (1, 2, or 3).

16.4.20.3 Descriptors

A transfer descriptor is a set of values that maps to a set of logical channel configuration registers. The descriptor contains the parameters associated with a transfer profile (transfer size, source or destination addresses, etc). Four different types of transfer descriptors are supported to optimize the memory size required to store a long linked list and to minimize MPU use to create and maintain the descriptor list.

A transfer descriptor is a list of 32-bit values. A descriptor must be 32-bit aligned in memory. Only the 30 least-significant bits (LSBs) of the next-descriptor address pointer are updated from the descriptor, and the DMA4 forces the 2 LSBs to 0 on generation of the pointer address. The descriptor size is variable depends on the descriptor type and the `Nxt_Dv` and `Nxt_Sv` bit fields.

Transfer descriptor bit mapping is the same as DMA4 logical-channel configuration register bit mapping, with the following exceptions:

- `Src_Element_index` and `Dst_Element_index` are concatenated in the same 32-bit location.
- [DMA4_CICRi](#) (interrupt event mask)
- CFN (frame number)
- Bit fields
 - P: Corresponds to the `PAUSE_LINK_LIST` bit:
 - When set to 1 in the descriptor, the channel is suspended when the descriptor load completes.
 - The user must not set the `PAUSE_LINK_LIST` bit through the configuration port. Otherwise, behavior is undefined.
 - When set to 0 (through the configuration port) after pause, the linked-list channel resumes its transfer (either descriptor load or data load).
 - B: Corresponds to the end-of-block enable bit (`BLOCK_IE`) of the [DMA4_CICRi](#) register; valid only for type 3. This value is don't care for descriptor types 1 and 2, where [DMA4_CICRi](#) is fully specified.
 - `Nxt_Dv`, `Nxt_Sv`: Mapped in the [DMA4_CDPi](#) register. They indicate one of the following possibilities:
 - Next descriptor contains an updated destination or source address.
 - Next descriptor does not update the source or destination address, but increments the last source or destination address (from the end of the last transfer).
 - The next source address and/or destination address are the last valid ones in the configuration memory. This means that the corresponding location in the configuration memory is not updated (assuming that they were initialized at least once in the past). This is also called wrapping addressing.
 - `Next_Descriptor_Type`: Specifies the next descriptor type that corresponds to the `NEXT_DESCRIPTOR_TYPE` bit field in the [DMA4_CDPi](#) register

Table 16-17. Type 3 With Source or Destination Address Update

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|-------------|---------------------------------------------------|---|---|----|----|----------------|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|----|---|---|---|---|---|
| | 3 | 3 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 2 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| Ptr+ 0x8 | Source_Start_Address or Destination_Start_Address | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| Ptr+ 0x4 | N_type | | B | Dv | Sv | Element_number | | | | | | | | | | | | | | | | | | | | | | | | | | |

| | | | | | | | | | | | | | | | | | | | | | | | | | | | sv | | | | | |

16.4.20.4 Linked-List Control and Monitoring

16.4.20.4.1 Transfer Mode Setting

Four descriptor types are available in `DMA4_CDPi[9:8] TRANSFER_MODE` to distinguish the different transfer modes:

- `DMA4_CDPi[9:8] TRANSFER_MODE = 00`: The current channel is using normal mode.
- `DMA4_CDPi[9:8] TRANSFER_MODE = 01`: The current channel is using link-list channel mode for a type 1, 2, or 3 descriptor.

The reset value is normal mode (`DMA4_CDPi[9:8] TRANSFER_MODE = 0`).

16.4.20.4.2 Starting a Linked List

Like a nonlinked-list transfer, a link transfer starts under host control by enabling the associated logical channel (set the `DMA4_CCRi[7] ENABLE` bit to 1). The `DMA4_CDPi[10] FAST` bit sets the start mode of the link-list transfer:

In nonfast-start mode, the logical channel configuration is fully initialized so that the transfer can start without descriptor loading.

In fast-start mode, the descriptor pointer and other inputs are given. The channel starts by loading the descriptor and then starts the data transfer phase.

16.4.20.4.3 Monitoring a Linked-List Progression

In addition to the `DMA4_CCENi` (remaining elements) and `DMA4_CCFNi` (remaining frames) registers that are used to monitor the transfer progress, a per-channel register, `DMA4_CCDNi` (channel current active descriptor number), monitors which descriptor in the list is active. The user must initialize the `DMA4_CCDNi` register to 0 during the initial configuration. When the `DMA4_CCDNi` register is updated, the `DMA4_CCFNi` and the `DMA4_CCENi` registers are updated. The user must also initialize the `DMA4_CCFNi` and `DMA4_CCENi` registers to 0xFFFF and to 0xFFFFFFFF, respectively, to track the effective transfer start of synchronized transfer.

16.4.20.4.4 Interrupt During Linked-List Execution

Any logical channel source of interrupt can be triggered during a linked-list execution, if the interrupt source is enabled during the initial configuration in `CICR`. The `DMA4_CICRi` register can also be updated during the linked-list execution if descriptor types 1 and 2 are used.

The use of an interrupt event in a link execution can be difficult, because the link can progress in parallel with interrupt service routine (ISR) execution. This makes it difficult to synchronize them unless system assumptions are used. The most appropriate synchronization model is to get an interrupt-only on linked-list completion, when the last transfer block is complete. This prevents the interrupt from occurring during the link execution. An end-of-super-block interrupt event available in the `DMA4_CICRi` and `DMA4_CSRi` registers can be enabled at initial configuration or when using descriptor types 1 and 2. To prevent the use of descriptor type 1 or 2 to update `BLOCK_IE` (full `DMA4_CICRi` update), a dedicated `BLOCK_IE` bit field is also available in a type 3 descriptor.

16.4.20.4.5 Pause a Linked List

When the channel is suspended, it remains enabled.

The pause behaves differently, depending on the transfer mode:

- Normal transfer mode: If the user sets the [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit to 1, the channel completes the current read and write transactions and then suspends the channel. The channel can be resumed by setting the channel [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit to 0.
- Linked-list type 1, 2, or 3 mode: The user must not set the [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit through the configuration port; otherwise, transfer behavior is undefined.

A [PAUSE_LINK_LIST](#) bit (P) is set to 1 in the descriptor.

- The channel is suspended after the descriptor load, translation, and configuration memory update are complete.
- The linked list can be resumed by resetting the [DMA4_CDPi\[7\] PAUSE_LINK_LIST](#) bit (through the configuration port).

16.4.20.4.6 Stop a Linked List (Abort or Drain)

The channel can be stopped for a drain or an abort. These cases are exclusive.

16.4.20.4.6.1 Drain

- Drain conditions:

A channel is a drain candidate if it is a hardware-source-synchronized transfer with [DMA4_CCRi\[25\] BUFFERING_DISABLE = 0](#) and should not be doing any of the graphics operation (transparent copy or solid-color fill).

- Drain trigger:

A drain candidate channel is drained if it is disabled ([DMA4_CCRi\[7\] ENABLE = 0](#)) or if it receives a transaction error on the read port.

- Drain behavior with a type 1, 2, or 3 descriptor. Drain trigger can occur in two situations:
 - During descriptor loading: Any ongoing current transaction is complete and the channel is aborted.
 - During data loading: The read is completed at the boundary of the request (element/frame/packet/block boundary), the FIFO is drained to the destination, and then a [DRAIN_END](#) interrupt can be asserted.

16.4.20.4.6.2 Abort

- Abort condition:

A channel is an abort candidate if it is software-synchronized, hardware-destination-synchronized, solid color-fill, transparent-color fill, or hardware-source-synchronized with [DMA4_CCRi\[25\] BUFFERING_DISABLE = 1](#).

- Abort trigger:

A channel is an abort candidate if it is disabled ([DMA4_CCRi\[7\] ENABLE = 0](#)), if it receives a transaction error on the read or write port, or if there is a [MISALIGNMENT_ERROR](#).

- Abort behavior with a type 1, 2, or 3 descriptor:

If an abort trigger occurs, the channel aborts immediately after completion of current read/write transactions and then the FIFO is cleaned up.

In type 1, 2, or 3, if an abort trigger or drain trigger occurs during the descriptor load phase, the channel aborts.

16.4.20.4.7 Status Bit Behavior

This section describes the behavior of the [DMA4_CSRi\[6\] SYNC](#), [DMA4_CCRi\[9\] RD_ACTIVE](#) and [DMA4_CCRi\[10\] WR_ACTIVE](#) status bits:

- For a hardware-synchronized channel in linked-list mode, the [DMA4_CSRi\[6\] SYNC](#) bit becomes active ([DMA4_CSRi\[6\] SYNC = 1](#)) when the first data load transaction is scheduled and remains active

until the last data load transaction in the block (not super block) is descheduled (`DMA4_CSRI[6] SYNC = 0`). The SYNC bit is not active during the descriptor load phase.

- The `DMA4_CCRi[9] RD_ACTIVE` bit is active during the data load phase and the descriptor load phase. It becomes active when the first read transaction is scheduled. It becomes inactive:
 - When (during the descriptor load phase) the last descriptor write request is descheduled
 - When (during the data load phase) the last read transaction in the block (not super block) is descheduled for software-synchronized transfer or destination-synchronized transfer with prefetch enabled
 - When (during the data load phase) the last read transaction in the request (element/frame/packet/block sync) is descheduled for hardware-source-synchronized transfer or hardware-destination-synchronized transfer without prefetch
- The `DMA4_CCRi[10] WR_ACTIVE` bit is active only during the data load phase. It becomes active when the first write transaction is scheduled and becomes inactive:
 - Until the last write transaction in the block (not super block) is descheduled and the FIFO is cleaned up for software-synchronized transfer
 - Until the last write transaction in the request (element/frame/packet/block sync) is descheduled and the FIFO is cleaned up for hardware-source-synchronized transfer (with `DMA4_CCRi[25] BUFFERING_DISABLE = 0`) or hardware-destination-synchronized transfer.

16.4.20.4.8 *Linked-List Channel Linking*

Channel linking for inter and intra super blocks is supported for type 1, 2, and 3 descriptors.

Assume that CHx and CHz are linked-list channels using generic descriptors. If CHx is composed of N descriptors and CHz is composed of M descriptors, then in nonfast mode,

CHx: CHx[Data1] -> CHx[DES1] -> . -> CHx[DESN] -> CHx[DataN + 1]

CHz: CHz[Data1] -> CHz[DES1] -> . -> CHz[DESM] -> CHz[DataM + 1]

It is possible to link CHx to CHz or CHx to itself after the completion of the CHx transfer (end of super block). To do this, the user must set the `DMA4_CLNK_CTRLi[15] ENABLE_LNK` bit to 1 and the `DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID` bit to z (or to x for self linking) through the last descriptor using a type 1 descriptor. The sequence is:

CHx: CHx[Data1] -> CHx[DES1] -> . -> CHx[DESN] -> CHx[DataN+1] -> CHz: CHz[Data1] -> CHz[DES1] -> . -> CHz[DESM] -> CHz[DataM+1]

It is also possible to link CHx to CHz during the CHx transfer and before the end of super block. The user must set the `DMA4_CLNK_CTRLi[15] ENABLE_LNK` bit to 1 and the `DMA4_CLNK_CTRLi[4:0] NEXTLCH_ID` bit to z through descriptor p (CHx[DESp]) using a type 1 descriptor. The sequence is:

CHx: CHx[Data1] -> CHx[DES1] ->...-> CHx[DESp] -> CHx[Data(p + 1)] -> CHz[Data1] -> CHz[DES1] -> .

The user must continue the linking until channels CHx and CHz complete their super-block transfers; otherwise, the channels remain enabled.

NOTE: In channel linking, the head of a chain can be in fast mode or nonfast mode. All channels that are not in the head of the chain can be in nonfast mode only. In self-linking, the channel cannot be in fast mode.

NOTE: If channel CHx links to CHz in the middle of the superblock transfer (remember link bit can be set through Type-1 descriptor load), CHx will get disabled after the corresponding data load and enables the channel CHz.

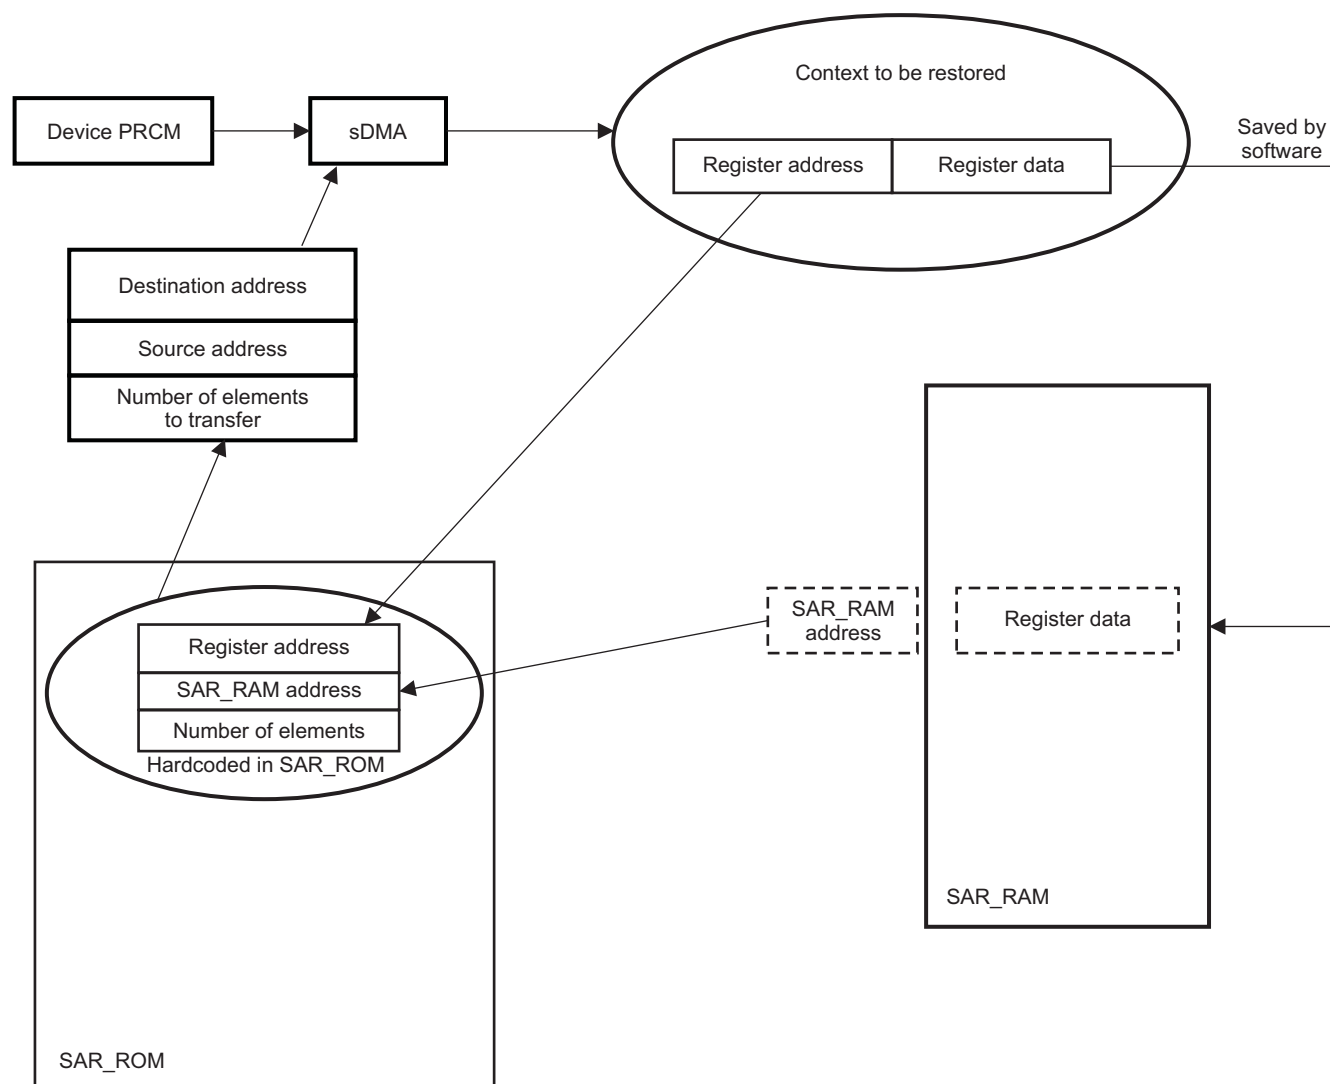

16.4.21 Auto-Restore Feature

The auto-restore feature is introduced mainly to accelerate the restore process, which otherwise is complex as well as time and resource consuming. In many system applications, it is required that the modem wake up and use only a few modules to wake up, without the main MPU (Cortex-A9 MPU) intervention. The MPU still might be in OFF mode; however, some modules might need to come out of OFF mode. The sDMA can be used to restore the register contents of these modules. The auto-restore feature consists in saving the registers data into a memory (SAR RAM sitting in the WKUP domain) that remains powered even during OFF-mode then it consists in retrieving automatically data when returning from OFF-mode.

The restore feature is enabled by default and cannot be disabled.

Figure 16-12 shows an overview of the save and restore mechanism using SAR RAM and SAR ROM.

Figure 16-12. Save and Restore Mechanism Overview Using SAR RAM and SAR ROM

dma-014

16.4.21.1 Save Process

The save process is done entirely by software; the sDMA module normally is not involved. The software must save the data to be restored in a dedicated location in SAR RAM. To reduce the save sequence execution time, the sDMA can be used with linked-list descriptors. These save descriptors are symmetrical with regards to descriptors that lay in the SAR ROM.

The register content to be saved can be the register value before going into OFF-mode or a value that is required on wake up. This means that the restored register value can be different from the last value of the register before going into OFF-mode.

The following registers are impacted:

- CM1 and CM2 configuration
Bits 0 of the CM_SHADOW_FREQ_CONFIG1 register and the CM_SHADOW_FREQ_CONFIG2 register are self-clearing and must be set at restore time. Thus, these data must always be overwritten in the SAR RAM.
- Because USBHOSTHS and USBTLL restore needs a particular sequencing, the software must overwrite data read from the following registers implied in phase2a and phase 2b:
 - **CM_L3INIT_HSUSBHOST_CLKCTRL_RESTORE**
 - **CM_L3INIT_HSUSBTLL_CLKCTRL_RESTORE**
 - **CM_SDMA_STATICDEP_RESTORE**

The USBHOSTHS and USBTLL modules must be put in a particular mode when saving (and restoring) their context. In the case of context saving, the software must follow the following sequence:

- Configure the L3INIT clock domain to SW_WKUP to ensure module transitions.
- Disable both modules.
- Assert the SAR_MODE pins.
- Enable back both modules. Optional clocks must be kept gated.
- Save both modules context.
- Disable both modules.
- Deassert SAR_MODE pins.
- At this point, the software might enable back both modules and get out L3INIT clock domain from the SW_WKUP state.

16.4.21.2 Restore Process

As explained earlier, every time modem wakes up, the MPU must not necessarily wake up. This needs an automated way of restore. E.g .when mobile is in roaming, and not in active use, it needs to change base stations. For this task, the MPU need not wake up, only a few peripherals/subsystems need to be in ON mode. Before executing any task, we need to restore their register contents.

16.4.21.2.1 PRCM and sDMA interaction During Restore Phase

Restore is performed during three phases. At the end of each phase, the sDMA stops and waits for the PRCM to perform the next phase transfer. For more information, see the *Device Off Mode Wake-Up Sequences* section in [Chapter 3, Power, Reset and Clock Management](#).

16.4.21.2.2 sDMA Descriptors Description

The restore phase is automatically done by the sDMA. The sDMA gets the register address (**Destination address**), the **number of elements** to transfer and the address of the data to transfer (**Source address**) from SAR ROM. As mentioned previously the register data is stored in the SAR RAM.

SAR ROM content:

The SAR ROM contains two types of descriptors that the DMA-4 should use:

- Type-1 descriptors
- Type-3 descriptors with both source and destination address update

Type-1 descriptor (48 bytes) is to be used at the beginning of each phase. Indeed, in addition of source and destination address and number of elements, it contains the required data that initializes the sDMA. [Table 16-13](#) shows the Type-1 descriptor structure.

Type-3 descriptors (16 bytes) are to be used for subsequent sDMA transfers and contain mainly source and destination address and number of elements. [Table 16-16](#) shows the Type-3 descriptor structure.

Figure 16-13 shows an example of SAR ROM code (Type-3 Descriptor):

Figure 16-13. Type-3 SAR ROM Code Example

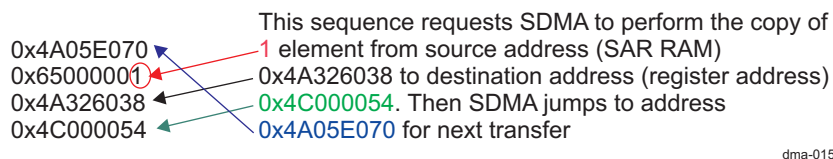

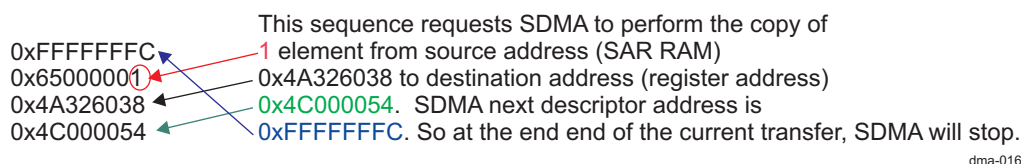

Figure 16-14 shows an example of Last DMA transfer (Type-3 Descriptor):

To indicate to the DMA that this is the last transfer, then the next descriptor address must be set to 0xFFFFFFF0 as in the example below :

Figure 16-14. Type-3 SAR ROM Last transfer Example

16.4.21.3 SAR RAM

The SAR RAM contains the **data** which needs to be maintained during OFF-mode. The SAR RAM is split into 3 banks:

Table 16-18. SAR RAM Allocation

| Access Mode | Bank | Address Range |
|--------------------|---------------|-------------------------------|
| public | 1 (SAR_RAM_1) | 0x4A32_6000 0x4A32_6FFF (4kB) |
| public, for IO Pad | 2 (SAR_RAM_2) | 0x4A32_7000 0x4A32_73FF (1kB) |
| public | 3 (SAR_RAM_3) | 0x4A32_8000 0x4A32_87FF (2kB) |

16.4.21.4 SAR ROM

The SAR ROM contains the list of registers that need to be saved before OFF-mode and so restored after OFF-mode and contains also the location where the register data is stored in SAR RAM. The SAR ROM start address is 0x4A05_E000.

When exiting OFF-mode, PRCM automatically redirects sDMA to address:

- 0x4A05_E000 for phase 1 (in SAR ROM)
- 0x4A05_E030 for phase 2a (in SAR ROM)
- 0x4A05_E060 for phase 2b (in SAR ROM)

The SAR ROM is build so that sDMA will perform all the transfers for each phase. At the end of each phase, sDMA will stop. PRCM will then request to perform the next phase transfer depending on wakeup source.

Remarks:

- Phase 1 is always to happen, the RESTORE mechanism is enabled by default and can not be disabled.
- Phase 2 (2a and 2b) is to happen depending on the wake-up source from OFF-mode. So it is mandatory to correctly fill the SAR RAM locations used for USB restore, even USB is not used because the restore sequence will happen.
- USB host RESTORE is to be performed before USB TLL RESTORE

NOTE: Some consecutive address registers cannot be saved/restored with burst. This is the case for:

- CLK1_DSS_BW_REGULATOR.L3_BW_R_BANDWIDTH and CLK1_DSS_BW_REGULATOR.L3_BW_R_WATERMARK registers
- CLK2_XXX_BW_REGULATOR.L3_BW_R_BANDWIDTH and CLK2_XXX_BW_REGULATOR.L3_BW_R_WATERMARK registers, where XXX stands for ISS, IVAHD and SGX.

To avoid sDMA transfer failure, the transfer of the above register is performed using a single sDMA transfer.

16.4.21.5 SAR RAM Memory Allocation Reserved for Save and Restore

The memory size of the SAR RAM reserved for the Save and Restore mechanism is:

- 57% (2344 bytes) reserved for the SAR mechanism from SAR_RAM_1. The whole SAR_RAM_1 size is 4KB.
- 40% (408 bytes) reserved for the SAR mechanism from SAR_RAM_2. The whole SAR_RAM_2 size is 1KB.
- 51% (1052 bytes) reserved for the SAR mechanism from SAR_RAM_3. The whole SAR_RAM_3 size is 2KB.

The free part of the SAR RAM can be used by the user software to store any data that needs to be in always-on memory.

16.4.21.6 Register Mapping in SAR RAM

Table 16-19 shows the SAR_RAM_1 memory mapping.

Table 16-19. SAR_RAM_1 Memory Mapping

16.5 sDMA Basic Programming Model

16.5.1 Setup Configuration

After a hardware reset, program all fields in the logical channel registers to default values for any channels used, because most fields are undefined following reset.

Before programming any DMA transfers, the priority arbitration rate and the maximum FIFO depth must be configured through the [DMA4_GCR](#) register, and any required interrupts must be enabled through the [DMA4_IRQENABLE_Lj](#) registers and the logical channel [DMA4_CICRi](#) registers.

Software clears the [DMA4_CSRi](#) register and the IRQSTATUS bit for the different interrupt lines before enabling the channel.

16.5.2 Software-Triggered (Nonsynchronized) Transfer

To program a software-triggered DMA transfer:

1. Configure the transfer parameters in the logical DMA channel registers:

- [DMA4_CSDPi](#):
 - Transfer ES (8 bits, 16 bits, or 32 bits) in DMA register bits [DMA4_CSDPi\[1:0\]](#)
 - Read and write port access types (single/burst), DMA register bits [DMA4_CSDPi\[8:7\]](#) and [DMA4_CSDPi\[15:14\]](#)
 - Source and destination endianness, DMA register bits [DMA4_CSDPi\[21\]](#) and [DMA4_CSDPi\[19\]](#)
 - Write mode (posted or nonposted) and DMA register bits [DMA4_CSDPi\[17:16\]](#)
 - Source or destination packed or nonpacked (if the ES is less than the read/write port size), DMA register bits [DMA4_CSDPi\[6\]](#) and [DMA4_CSDPi\[13\]](#)
- [DMA4_CENi](#): EN
- [DMA4_CFNi](#): FN per transfer block
- [DMA4_CSSAi](#) and [DMA4_CDSAi](#): Source and destination start address (aligned with transfer ES)
- [DMA4_CCRi](#):
 - Read and write port addressing modes, DMA register bits [DMA4_CCRi\[13:12\]](#) and [DMA4_CCRi\[15:14\]](#)
 - Priority bit for both read and write ports, DMA register bits [DMA4_CCRi\[6\]](#) and [DMA4_CCRi\[26\]](#)
 - DMA request number (set to 0 for a software-triggered transfer) and DMA register bits [DMA4_CCRi\[4:0\] = 0](#) and [DMA4_CCRi\[20:19\] = 0](#)
- [DMA4_CSEIi](#), [DMA4_CSFli](#), [DMA4_CDEIi](#), and [DMA4_CDFli](#): Source and destination element and frame indexes (depending on addressing mode)

2. Start the transfer through the enable bit in the channel [DMA4_CCRi](#) register and DMA register bit [DMA4_CCRi\[7\]](#)

The example below perform a DMA transfer on channel 10 of a 240*160 picture from RAM to RAM (0x80C00000 to 0x80F00000) :

```
UWORD32 RegVal = 0;
DMA4_t *DMA4;
DMA4 = (DMA4_t *)malloc(sizeof(DMA4_t));

/* Init. parameters */
DMA4->DataType = 0x2; // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0; // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0; // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]
DMA4->DestinationEndianism = 0; // DMA4_CSDPi[19]
DMA4->WriteMode = 0; // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0; // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi
DMA4->SourceElementIndex = 1; // DMA4_CSEIi
DMA4->SourceFrameIndex = 1; // DMA4_CSFli
DMA4->DestinationElementIndex = 1; // DMA4_CDEIi
DMA4->DestinationFrameIndex = 1; // DMA4_CDFli
DMA4->ReadPortAccessMode = 1; // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 1; // DMA4_CCRi[15:14]
```

```

DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority = 0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]

/* 1) Configure the transfer parameters in the logical DMA registers */
/*-----*/

/* a) Set the data type CSDP[1:0], the Read/Write Port access type CSDP[8:7]/[15:14], the
Source/dest endiansim CSDP[21]/CSDP[19], write mode CSDP[17:16], source/dest packed or non-
packed CSDP[6]/CSDP[13]*/

// Read CSDP
RegVal = DMA4_CSDP_CH10;

// Build reg
RegVal = ((RegVal & ~0x3) | DMA4-DataType );
RegVal = ((RegVal & ~(0x3 << 7)) | (DMA4->ReadPortAccessType << 7));
RegVal = ((RegVal & ~(0x3 << 14)) | (DMA4->WritePortAccessType << 14));

/* d) Set the Source/dest start address index CSSA[31:0]/CDSA[31:0]*/

DMA4_CSSA_CH10 = DMA4->SourceStartAddress; // address start
DMA4_CDSA_CH10 = DMA4->DestinationStartAddress; // address dest

/* e) Set the Read Port addressing mode CCR[13:12], the Write Port addressing mode CCR[15:14],
read/write priority CCR[6]/CCR[26], the current LCH CCR[20:19]=00 and CCR[4:0]=00000*/

// Read CCR
RegVal = DMA4_CCR_CH10;

// Build reg
RegVal = ((RegVal & ~(0x3 << 12)) | (DMA4->ReadPortAccessMode << 12));
RegVal = ((RegVal & ~(0x3 << 14)) | (DMA4->WritePortAccessMode << 14));
RegVal = ((RegVal & ~(0x1 << 6)) | (DMA4->ReadPriority << 6));
RegVal = ((RegVal & ~(0x1 << 26)) | (DMA4->WritePriority << 26));
RegVal &= 0xFFFCFFFE0 ;

// Write CCR
DMA4_CCR_CH10 = RegVal;

/* f)- Set the source element index CSEI[15:0]*/

DMA4_CSEI_CH10 = DMA4->SourceElementIndex;

/* g)- Set the source frame index CSFI[15:0]*/

DMA4_CSFI_CH10 = DMA4->SourceFrameIndex ;

```

```

/* h)- Set the destination element index CDEI[15:0]*/

DMA4_CDEI_CH10 = DMA4->DestinationElementIndex;

/* i)- Set the destination frame index CDFI[31:0]*/

DMA4_CDFI_CH10 = DMA4->DestinationFrameIndex;

/* 2) Start the DMA transfer by Setting the enable bit CCR[7]=1 */
/*-----*/

//write enable bit
DMA4_CCR_CH10 |= 1 << 7; /* start */

```

16.5.3 Hardware-Synchronized Transfer

To monitor a hardware synchronized DMA transfer, initialize the [DMA4_CDACi](#) register before the software enable.

To configure an LCh to synchronize by element, packet, frame, or block, the frame synchronization [DMA4_CCRi\[5\]](#) FS bit and the block synchronization [DMA4_CCRi\[18\]](#) BS bit register must be programmed. For all the following synchronized transfers (element, packet, frame or block synchronized transfers) User must set first : [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC to 1 when the source triggers on the DMA request and [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC to 0 when the Destination triggers on the DMA request. Note: User must take care when setting the [DMA4_CCRi\[23\]](#) PREFETCH bit it is in conjunction with [DMA4_CCRi\[24\]](#) SEL_SRC_DST_SYNC bit.

- To configure an LCh to transfer one element per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 4. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 5. Set the Read Port addressing mode in the [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field.
 6. Set the Write Port addressing mode in the [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 7. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 8. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.
 9. Set both FS and BS to 0 in [DMA4_CCRi\[5\]](#) FS and [DMA4_CCRi\[18\]](#) BS.
 10. Set to 1 the channel enable bit [DMA4_CCRi\[7\]](#) EN.
- To configure an LCh to transfer one frame per DMA request:
 1. Set the number of DMA request associated to the current LCH in the [DMA4_CCRi\[20:19\]](#) SYNCHRO_CONTROL_UPPER and [DMA4_CCRi\[4:0\]](#) SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the [DMA4_CSDPi\[1:0\]](#) DATA_TYPE bit field.
 3. Set the number of element per frame in the [DMA4_CENi\[23:0\]](#) CHANNEL_ELMNT_NBR bit field.
 4. Set the Read Port access type (single or burst access) in the [DMA4_CSDPi\[8:7\]](#) SRC_BURST_EN bit field.
 5. Set the Write Port access type (single or burst access) in the [DMA4_CSDPi\[15:14\]](#) DST_BURST_EN bit field.
 6. Set the Read Port addressing mode in the [DMA4_CCRi\[13:12\]](#) SRC_AMODE bit field.
 7. Set the Write Port addressing mode in the [DMA4_CCRi\[15:14\]](#) DST_AMODE bit field.
 8. Set the Read start address in the [DMA4_CSSAi\[31:0\]](#) SRC_START_ADRS bit field.
 9. Set the Write start address in the [DMA4_CDSAi\[31:0\]](#) DST_START_ADRS bit field.

10. Set FS to 1 and BS to 0, respectively, in `DMA4_CCRi[5]` FS and `DMA4_CCRi[18]` BS.
11. Set to 1 the channel enable bit `DMA4_CCRi[7]` EN.
- To configure an LCh to transfer one block per DMA request:
 1. Set the number of DMA request associated to the current LCH in the `DMA4_CCRi[20:19]` SYNCHRO_CONTROL_UPPER and `DMA4_CCRi[4:0]` SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the `DMA4_CSDPi[1:0]` DATA_TYPE bit field.
 3. Set the number of element per frame in the `DMA4_CENi[23:0]` CHANNEL_ELMNT_NBR bit field.
 4. Set in the `DMA4_CFNi[15:0]` CHANNEL_FRAME_NBR bit field the number of frame (transfers), to take place before the LCH gets disabled.
 5. Set the Read Port access type (single or burst access) in the `DMA4_CSDPi[8:7]` SRC_BURST_EN bit field.
 6. Set the Write Port access type (single or burst access) in the `DMA4_CSDPi[15:14]` DST_BURST_EN bit field.
 7. Set the Read Port addressing mode in the `DMA4_CCRi[13:12]` SRC_AMODE bit field.
 8. Set the Write Port addressing mode in the `DMA4_CCRi[15:14]` DST_AMODE bit field.
 9. Set the Read start address in the `DMA4_CSSAi[31:0]` SRC_START_ADRS bit field.
 10. Set the Write start address in the `DMA4_CDSAi[31:0]` DST_START_ADRS bit field.
 11. Set FS to 0 and BS to 1, respectively, in `DMA4_CCRi[5]` FS and `DMA4_CCRi[18]` BS.
 12. Set to 1 the channel enable bit `DMA4_CCRi[7]` EN.
- To configure an LCh to transfer one packet per DMA request:
 1. Set the number of DMA request associated to the current LCH in the `DMA4_CCRi[20:19]` SYNCHRO_CONTROL_UPPER and `DMA4_CCRi[4:0]` SYNCHRO bit field.
 2. Set the data type, also referenced as element size (ES), in the `DMA4_CSDPi[1:0]` DATA_TYPE bit field.
 3. Set the number of elements per packet to transfer: If the packet requestor is in the source, set `DMA4_CCRi[24]` SEL_SRC_DST_SYNC to 1 and set the packet element number in the `DMA4_CSFli` register and set the addressing mode of source to constant addressing in `DMA4_CCRi[13:12]` SRC_AMODE bit field; else, if the packet requestor is in the destination, set the `DMA4_CCRi[24]` SEL_SRC_DST_SYNC to 0 and set the packet element number in the `DMA4_CDFli` register and set the addressing mode of destination to constant addressing in `DMA4_CCRi[15:14]` DST_AMODE bit field.
 4. Set the number of elements per frame in the `DMA4_CENi[23:0]` CHANNEL_ELMNT_NBR bit field.
 5. Set in the `DMA4_CFNi[15:0]` CHANNEL_FRAME_NBR bit field the number of frames (transfers), to take place before the LCH gets disabled.
 6. Set the element number in the packet in the `DMA4_CSFli[15:0]` PKT_ELNT_NBR, if constant addressing or post-incremented addressing modes are used in the source side. However, the number of element in the packet is set in the `DMA4_CDFli[15:0]` PKT_ELNT_NBR if constant addressing mode is used in the destination side.
 7. Set the Read Port access type (single or burst access) in the `DMA4_CSDPi[8:7]` SRC_BURST_EN bit field.
 8. Set the Write Port access type (single or burst access) in the `DMA4_CSDPi[15:14]` DST_BURST_EN bit field.
 9. Set the Read Port addressing mode in the `DMA4_CCRi[13:12]` SRC_AMODE bit field.
 10. Set the Write Port addressing mode in the `DMA4_CCRi[15:14]` DST_AMODE bit field.
 11. Set the Read start address in the `DMA4_CSSAi[31:0]` SRC_START_ADRS bit field.
 12. Set the Write start address in the `DMA4_CDSAi[31:0]` DST_START_ADRS bit field.
 13. Set FS to 1 and BS to 1, respectively, in `DMA4_CCRi[5]` FS and `DMA4_CCRi[18]` BS.
 14. Set to 1 the channel enable bit `DMA4_CCRi[7]` EN.

NOTE: It is possible to stop a transfer by disabling the channel by resetting the [DMA4_CCRi\[7\] ENABLE](#) bit.

16.5.4 Synchronized Transfer Monitoring Using CDAC

The [DMA4_CDACi](#) register is writable and non-initialized (value undefined). It can be initialized to monitor a transfer by applying the following programming model:

1. Write 0 in the [DMA4_CDACi](#) register.
2. Enable the channel.
3. If a time-out occurs, read [DMA4_CDACi](#) register.
4. If [DMA4_CDACi](#) != 0 (it is the value configured in [DMA4_CDACi](#)):
This indicates that the corresponding transfer has started. User can then rely on [DMA4_CCENi](#) and [DMA4_CCFNi](#) element and frame counters.
Else, if [DMA4_CDACi](#) = 0 (it is the value configured in the [DMA4_CDACi](#)):
This indicates that the corresponding transfer did not start.

16.5.5 Concurrent Software and Hardware Synchronization

This section describes thread allocation only; it does not describe the entire transfer. Because synchronized transfers are latency critical, you must allocate a thread at least on the synchronized target side.

Even for multiple concurrent channels, thread reservation ensures that when a hardware DMA request arrives, the read/write scheduler finds available thread(s) to initiate a channel schedule and issue a read/write transaction.

Consider six concurrent channels:

- Channels 0, 1, 2, and 3 are dedicated to memory-memory transfer; they are software triggered and not synchronized.
- Channel 4 is dedicated to memory-peripheral transfer, hardware triggered, and synchronized on the write side.
- Channel 5 is dedicated to peripheral-memory transfer, hardware triggered, and synchronized on the read side.

To perform thread reservation:

1. Allow thread reservation for priority channel 4 and channel 5:
Reserve one thread (Read ThreadID 0) on the read port and one thread (Write ThreadID 0) on the write port: set the [DMA4_GCR\[13:12\] HI_THREAD_RESERVED](#) bit field to 0x1.
2. Specify channel priority:
Channel 4 is a write high priority channel: set [DMA4_CCRi\[26\] WRITE_PRIORITY](#) = 1.
Channel 5 is a read high priority channel: set [DMA4_CCRi\[6\] READ_PRIORITY](#) = 1.

16.5.6 Chained Transfer

A chained DMA transfer can be programmed as follows:

1. Configure the transfer parameters for each logical DMA channel in the chain as in step 1 for either the synchronized or non-synchronized transfers describe in [Section 16.5.5, Concurrent Software and Hardware Synchronization](#).
2. For each channel in the chain, configure the [DMA4_CLNK_CTRLi](#) register as follows:
 - Next logical DMA channel number (for a looping chained transfer link last channel to first channel number), in the [DMA4_CLNK_CTRLi\[4:0\] NEXTLCH_ID](#) bit field.
 - Include the logical channel to the chain and enable link by setting the [DMA4_CLNK_CTRLi\[15\] ENABLE_LNK](#) bit.
 - For a non-looping chain, the last logical channel in the chain must have the

[DMA4_CLNK_CTRLi](#)[15] ENABLE_LNK bit set to 0 to indicate the end of the chain.

3. Enable the transfer through the enable bit in the first logical channel [DMA4_CCRi](#)[7] ENABLE bit. All other channels in the chain must be disabled. Each channel is enabled automatically in turn when the previous logical channel transfer completes. A non-synchronized transfer starts immediately; a hardware-synchronized transfer starts when the DMA request line corresponding to the first DMA channel in the chain is asserted.

To stop a looping chained transfer, disable the [DMA4_CLNK_CTRLi](#)[15] ENABLE_LNK bit (by setting it to 0x0), of the final channel transfer.

In the RAM-to-RAM copy example, to copy in loop, it is possible to link channel 10 on itself. The following line can be added in the channel configuration:

```
/* g) Set link for loop */
DMA4_CLINK_CTRL_CH10 = 0x0000800A;
```

16.5.7 90-Degree Clockwise Image Rotation

The 90-degree clockwise image rotation example described in [Section 16.4.5, Addressing Modes](#), can be programmed as follows:

1. Configure the transfer parameters in the logical DMA channel registers:

- [DMA4_CSDPi](#):
 - Transfer ES = 32-bit (32 bpp), [DMA4_CSDPi](#)[1:0] DATA_TYPE bit field
 - Read and write port access types = maximum burst size supported by memory device, [DMA4_CSDPi](#)[8:7] SRC_BURST_EN and [DMA4_CSDPi](#)[15:14] DST_BURST_EN bit fields
 - Source and destination endianness, [DMA4_CSDPi](#)[21] SRC_ENDIAN and [DMA4_CSDPi](#)[19] DST_ENDIAN bits
 - Write mode = posted with last element nonposted, [DMA4_CSDPi](#)[17:16] WRITE_MODE bit field
 - Source and destination packed = Yes (although destination writes do not benefit because EI1), [DMA4_CSDPi](#)[6] SRC_PACKED and [DMA4_CSDPi](#)[13] DST_PACKED bits
- [DMA4_CENi](#): EN = 240
- [DMA4_CFNi](#): FN per transfer block = 160
- [DMA4_CSSAi](#): Source start address = 0x100000
- [DMA4_CDSAi](#): destination start address = 0x20013E
- [DMA4_CCRi](#):
 - Read and write port addressing modes = double-index addressing mode for both or post-increment addressing on source and double-index addressing on destination, [DMA4_CCRi](#)[13:12] SRC_AMODE and [DMA4_CCRi](#)[15:14] DST_AMODE bit fields
 - Low or high priority, [DMA4_CCRi](#)[6] READ_PRIORITY bit
 - DMA request number = 0 (for software-triggered transfer), [DMA4_CCRi](#)[4:0] SYNCHRO_CONTROL and [DMA4_CCRi](#)[20:19] SYNCHRO_CONTROL_UPPER bit fields
- [DMA4_CSEIi](#): Source EI = 1
- [DMA4_CSFli](#): Source frame index = 1
- [DMA4_CDEIi](#): destination EI = 637
- [DMA4_CDFli](#): destination frame index = 152967

2. Start the transfer through the enable bit in the channel [DMA4_CCRi](#) register.

The following parameters are used to perform this rotation from 0x80C00000 RAM address to 0x80F00000, with the same code used in [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```
/* Init. parameters */
DMA4->DataType = 0x2; // DMA4_CSDPi[1:0]
DMA4->ReadPortAccessType = 0x3; // DMA4_CSDPi[8:7]
DMA4->WritePortAccessType = 0x3; // DMA4_CSDPi[15:14]
DMA4->SourceEndiansim = 0; // DMA4_CSDPi[21]
DMA4->DestinationEndianness = 0; // DMA4_CSDPi[19]
```

```

DMA4->WriteMode = 0x2; // DMA4_CSDPi[17:16]
DMA4->SourcePacked = 0x1; // DMA4_CSDPi[6]
DMA4->DestinationPacked = 0x1; // DMA4_CSDPi[13]
DMA4->NumberOfElementPerFrame = 240; // DMA4_CENi
DMA4->NumberOfFramePerTransferBlock = 160; // DMA4_CFNi
DMA4->SourceStartAddress = 0x80C00000; // DMA4_CSSAi
DMA4->DestinationStartAddress = 0x80F00000; // DMA4_CDSAi
DMA4->SourceElementIndex = 1; // DMA4_CSEIi
DMA4->SourceFrameIndex = 1; // DMA4_CSFII
DMA4->DestinationElementIndex = 637; // DMA4_CDEIi
DMA4->DestinationFrameIndex = -152967; // DMA4_CDFII
DMA4->ReadPortAccessMode = 0x3; // DMA4_CCRi[13:12]
DMA4->WritePortAccessMode = 0x3; // DMA4_CCRi[15:14]
DMA4->ReadPriority = 0; // DMA4_CCRi[6]
DMA4->WritePriority = 0; // DMA4_CCRi[23]
DMA4->ReadRequestNumber = 0; // DMA4_CCRi[4:0]
DMA4->WriteRequestNumber = 0; // DMA4_CCRi[20:19]

```

16.5.8 Graphic Operations

- Transparent copy:
 1. Set the [DMA4_CCRi\[17\]](#) TRANSPARENT_COPY_ENABLE bit to 1
 2. Set the [DMA4_CCRi\[16\]](#) CONST_FILL_ENABLE bit to 0
 3. Set the value of the key color in the [DMA4_COLORi\[15:0\]](#) COLOR_KEY bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```

DMA4_CCR_CH10 &= ~(0x1 << 16);
DMA4_CCR_CH10 |= 0x1 << 17;
DMA4_COLOR_CH10 = 0x00000003;

```

- Solid Color fill:
 1. Set the [DMA4_CCRi\[16\]](#) CONST_FILL_ENABLE bit to 1
 2. Set the [DMA4_CCRi\[17\]](#) TRANSPARENT_COPY_ENABLE bit to 0
 3. Set the value of key the color in the [DMA4_COLORi\[15:0\]](#) SOLID_COLOR bit field

To perform this graphic operation, the following lines can be added to the example of [Section 16.5.2, Software-Triggered \(Nonsynchronized\) Transfer](#).

```

DMA4_CCR_CH10 &= ~(0x1 << 17);
DMA4_CCR_CH10 |= 0x1 << 16;
DMA4_COLOR_CH10 = 0x00000003;

```

16.5.9 Linked-List Programming Guidelines

- With the exception of the [DMA4_CCRi\[7\]](#) ENABLE bit and the [DMA4_CDPi\[7\]](#) PAUSE_LINK_LIST bit during a linked-list transfer (descriptor load phase or data load phase), avoid programming any register through the configuration port.
- Before enabling any linked-list transfer, ensure that all global registers and all registers in the descriptor are initialized. Some static channel registers (registers that are not updated by the descriptor to be loaded) must also be initialized correctly:
 - For type 2, the following registers must be initialized with consistent values:
 - All global registers
 - [DMA4_CCRi](#)
 - [DMA4_CSDPi](#)
 - [DMA4_CLNK_CTRLi](#)
 - For type 3, the following registers must be initialized with consistent values:
 - All global registers
 - [DMA4_CCRi](#)
 - [DMA4_CSDPi](#)

- [DMA4_CLNK_CTRLi](#)
- [DMA4_CICRi](#)
- [DMA4_CFNi](#)
- In case of a linked list with descriptor types 2 and 3, the content of the [DMA4_CCRi](#) register must not change during super-block life.
- The PAUSE_LINK_LIST bit must not be set in the initialization phase.

16.6 sDMA Register Manual

16.6.1 sDMA Instance Summary

Table 16-22. sDMA Instance Summary

| Module Name | Base Address | Size |
|-------------|--------------|------|
| sDMA | 0x4A05 6000 | 4KB |

16.6.2 sDMA Registers

16.6.2.1 sDMA Register Summary

Index i represents the logical channel number (where $i = 0$ to 31). The offset address for some registers is calculated from channel c number. For example, register DMA4_CCR10 (channel 10) has an offset address of $10 \times 0x60 = 0x3C0$, and so a physical address of $0x4A05\ 6080 + 0x3C0 = 0x4A05\ 6440$.

Index j represents the interrupt line number (where $j = 0$ to 3). The offset address for some registers is calculated from channel c number. For example, register DMA4_IRQSTATUS_L3 (line 3) has an offset address of $3 \times 0x4 = 0xC$, and so a physical address of $0x4A05\ 6008 + 0xC = 0x4A05\ 6014$.

Table 16-23. sDMA Registers Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | sDMA L3 Base Address |
|--------------------------|------|-----------------------|-----------------------------|-----------------------------|

⁽³⁾ i = 0 to 31**16.6.2.2 sDMA Register Description**

NOTE: Some registers have no reset value (marked with -) because of hardware implementation in memory. Software must ensure the correct programming of these registers, if needed.

Shadow registers are used to read run-time registers such as CCEN, CCFN, CDAC, and CSAC. Typically, when accessed in 8-bit or 16-bit access for two consecutive accesses, the value of the previous registers can change. A shadow register holds the entire value to let the next access recover the remaining 24 bits or 16 bits.

For non-32-bit transactions, start reading or writing from the LSByte first to enable the register update. There is no issue for 32-bit read-write transactions.

| Bits | Field Name | Description | Type | Reset |
|-------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:25 | RESERVED | Write 0's for future compatibility. Read returns 0. | RW | 0x00 |
| 24 | CHANNEL_ID_GATE | Gates the Channel ID bus monitoring on both Read and Write ports 0x0: Gates the Channel ID qualifiers on both Read and Write Ports 0x1: Does not gate the Channel ID qualifiers on both Read and Write Ports | RW | 0x0 |
| 23:16 | ARBITRATION_RATE | Arbitration switching rate between prioritized and regular channel queues | RW | 0x01 |
| 15:14 | HI_LO_FIFO_BUDGET | Allow to have a separate Global FIFO budget for high and low priority channels. For Hi priority Channel: (Per_channel_Maximum FIFO depth + 1) x Number of active High priority Channel =< High Budget FIFO For Low priority channel: (Per_channel_Maximum FIFO depth + 1) x Number of active Low priority Channel =< Low Budget FIFO 0x0: no fixed budget for neither higher nor lower priority channel 0x1: 75% of FIFO for low priority and 25% for high priority channels 0x2: 25% of FIFO for low priority and 75% for high priority channels 0x3: 50% of FIFO for low priority and 50% for high priority channels | RW | 0x0 |
| 13:12 | HI_THREAD_RESERVED | Allow thread reservation for high priority channel on both read and write ports. 0x0: No ThreadID is reserved on the Read Port for high priority channels. No ThreadID is reserved on the Write Port for high priority channels. 0x1: Read Port ThreadID 0 is reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x2: Read port ThreadID 0 and ThreadID 1 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. 0x3: Read PortThreadID 0, ThreadID 1 and ThreadID 2 are reserved for high priority channels. Write Port ThreadID 0 is reserved for high priority channels. | RW | 0x0 |
| 11:8 | RESERVED | Write 0's for future compatibility. Read returns 0. | RW | 0x0 |
| 7:0 | MAX_CHANNEL_FIFO_DEPTH | Maximum FIFO depth allocated to one logical channel. Maximum FIFO depth can not be 0x0. It should be at least 0x1 or greater. Note that If channel limit is less than destination burst size enough data will not be accumulated in the data FIFO and it will never be sent out on the WR port. The burst size should be less than the FIFO limit specified in this bit field. | RW | 0x10 |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:30 | RESERVED | Write 0's for future compatibility. Read returns 0. | RW | 0x0 |
| 29:27 | RESERVED | Reserved | RW | 0x0 |
| 26 | WRITE_PRIORITY | Channel priority on the Write side 0x0: Channel has low priority on the Write side during the arbitration process 0x1: Channel has high priority on Write sided during the arbitration process | RW | 0 |
| 25 | BUFFERING_DISABLE | This bit allows to disable the default buffering functionality when transfer is source synchronized. 0x0: buffering is enable across element/packet when source is synchronized to element, packet, frame or bolcks 0x1: buffering is disabled across element/packet when source is synchronized to element, packet, frame or bolcks | RW | - |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 24 | SEL_SRC_DST_SYNC | Specifies that element, packet, frame or block transfer (depending on CCR.bs and CCR.fs) is triggered by the source or the destination on the DMA request 0x0: Transfer is triggered by the destination. If synch on packet the packet element number is specified in the CDFI register 0x1: Transfer is triggered by the source. If synchronized on packet the packet element number is specified in the CSFI register | RW | - |
| 23 | PREFETCH | Enables the prefetch mode 0x0: Prefetch mode is disabled. When Sel_Src_Dst_Sync=1 transfers are buffered and pipelined between DMA requests 0x1: Prefetch mode is enabled. Prefetch mode is active only when destination is synchronised. It is SW user responsibility not to have at the same time Prefetch=1 when Sel_Src_Dst_Sync=1. This mode is not supported | RW | 0 |
| 22 | SUPERVISOR | Enables the supervisor mode 0x0: Supervisor mode is disabled 0x1: Supervisor mode is enabled | RW | 0 |
| 21 | RESERVED | Reserved | RW | 0 |
| 20:19 | SYNCHRO_CONTROL_UPPER | Channel Synchronization control upper (used in conjunction with the 5 bits of synchro channel DMA4_CCRi[4:0]) Used in conjunction, as two msb, with the five bits of the synchro channel bit field. | RW | 0b00 |
| 18 | BS | Block synchronization This bit used in conjunction with the fs to see how the DMA request is serviced in a synchronized transfer | RW | - |
| 17 | TRANSPARENT_COPY_ENABLE | Transparent copy enable 0x0: Transparent copy mode is disabled 0x1: Transparent copy mode is enabled | RW | - |
| 16 | CONST_FILL_ENABLE | Constant fill enable 0x0: Constant fill mode is disabled 0x1: Constant fill mode is enabled | RW | 0 |
| 15:14 | DST_AMODE | Selects the addressing mode on the Write Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode | RW | 0bxx |
| 13:12 | SRC_AMODE | Selects the addressing mode on the Read Port of a channel. 0x0: Constant address mode 0x1: Post-incremented address mode 0x2: Single index address mode 0x3: Double index address mode | RW | 0bxx |
| 11 | RESERVED | Write 0's for future compatibility. Read returns 0. | RW | 0 |
| 10 | WR_ACTIVE | Indicates if the channel write context is active or not Read 0x0: Channel is not active on the write port Read 0x1: Channel is currently active on the write port | R | 0 |
| 9 | RD_ACTIVE | Indicates if the channel read context is active or not Read 0x0: Channel is not active on the read port Read 0x1: Channel is currently active on the read port | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------|
| 8 | SUSPEND_SENSITIVE | Logical channel suspend enable bit 0x0: The channel ignores the MSuspend even if EMUFree is set to 0. 0x1: If EMUFree is set to 0 and MSuspend comes in then all current OCP services (single transaction or burst transaction as specified in the corresponding CSDP register) have to be completed before stopping processing any more trasactions | RW | 0 |
| 7 | ENABLE | Logical channel enable. It is SW responsibility to clear the CSR register and the IRQSTATUS bit for the different interrupt lines before enabling the channel. 0x0: The logical channel is disabled 0x1: The logical channel is enabled | RW | 0 |
| 6 | READ_PRIORITY | Channel priority on the read side 0x0: Channel has low priority on the Read side during the arbitration process 0x1: Channel has high priority on read sided during the arbitration process | RW | 0 |
| 5 | FS | Frame synchronization This bit used in conjunction with the BS to see how the DMA request is serviced in a synchronized transfer FS=0 and BS=0: An element is transferred once a DMA request is made. FS=0 and BS=1: An entire block is transferred once a DMA request is made. FS=1 and BS=0: An entire frame is transferred once a DMA request is made. FS=1 and BS=1: A packet is transferred once a DMA request is made. All these different transfers can be interleaved on the port with other DMA requests. | RW | - |
| 4:0 | SYNCHRO_CONTROL | Channel synchronization control This bit field used in conjunction with the second_level_synchro_control_upper (as two msb) 0000000 : Is reserved for non synchronized LCH transfer xxxxxxx (from 1 to 127)There are 127 possible DMA request to assign to any LCH. Note: The channel synchronization control registers are 1-based. For example, to enable the S_DMA_1 request, DMA4_CCR[4:0] SYNCHRO_CONTROL must be set to 0x2 (DMA request number + 1). | RW | 0b00000 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:17 | RESERVED | Write 0's for future compatibility. Read returns 0. | RW | 0x0000 |
| 16:15 | RESERVED | Reserved for debug (Monitor descriptor/data load phase), Write 0's for future compatibility, Read returns 0 | RW | 0x0 |
| 14 | SUPER_BLOCK | End of Super block event | RW | 0 |
| 13 | RESERVED | Reserved | RW | 0 |
| 12 | DRAIN_END | End of channel draining | RW | 0 |
| 11 | MISALIGNED_ADRS_ERR | Misaligned address error event Read 0x0: No address error Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: An address error has been occurred | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 10 | SUPERVISOR_ERR | Supervisor transaction error event Read 0x0: No supervisor transaction error Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: A supervisor transaction error has been occurred | RW | 0 |
| 9 | RESERVED | Reserved | RW | 0 |
| 8 | TRANS_ERR | Transaction error event Read 0x0: No transaction error Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: A transaction error has been occurred | RW | 0 |
| 7 | PKT | End of Packet transfer Read 0x0: The current packet transfer has not been finished Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The current packet has been transferred | RW | 0 |
| 6 | SYNC | Synchronization status of a channel. Read 0x0: Logical channel is not scheduled or servicing a non synchronized DMA request. Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: Logical channel is servicing a synchronized DMA request | RW | 0 |
| 5 | BLOCK | End of block event Read 0x0: The current block transfer has not been finished Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The current block has been transferred | RW | 0 |
| 4 | LAST | Last frame (start of last frame) Read 0x0: The start of the last frame to transfer is not reached Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The start of the last frame to transfer is reached | RW | 0 |
| 3 | FRAME | End of frame event Read 0x0: The end of current transferred frame is not reached Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The end of current transferred frame is reached | RW | 0 |
| 2 | HALF | Half of frame event. Read 0x0: The half of current transferred frame is not reached Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: The half of current transferred frame is reached | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 1 | DROP | Synchronization event drop occurred during the transfer Read 0x0: No synchronization collision Write 0x0: Status bit unchanged Write 0x1: Status bit is reset Read 0x1: A synchronization collision has been occurred | RW | 0 |
| 0 | RESERVED | Write 0's for future compatibility. Read returns 0. | RW | 0 |

Interrupt Controllers

This chapter describes the interrupt controllers (INTCs) in the device.

| Topic | Page |
|----------------------------------------------------------------|-------------|
| 17.1 Interrupt Controllers Overview | 3609 |
| 17.2 Interrupt Controllers Environment | 3611 |
| 17.3 Interrupt Controllers Integration | 3612 |
| 17.4 Interrupt Controllers Functional Description | 3618 |
| 17.5 Interrupt Controllers Register Manual | 3619 |

17.1 Interrupt Controllers Overview

The device provides three interrupt controller (INTC) modules, which handle interrupts at the device level:

- Cortex™-A9 MPU subsystem (MPUSS) interrupt controller (Cortex-A9 MPU INTC): This INTC module is a single functional unit that is integrated in the Cortex-A9 multiprocessor core alongside Cortex-A9 processors. It provides:
 - 128 hardware interrupt inputs
 - Generation of interrupts by software
 - Prioritization of interrupts
 - Masking of any interrupts
 - Distribution of the interrupts to the target Cortex-A9 processor(s)
 - Tracking the status of interrupts
 - Wake-up generator (WUGEN) module on external and local interrupts
- DSP subsystem (DSPSS) interrupt controller: This module is a specific combination of wake-up generator (WUGEN) and the C64x+ DSP INTC. It is used in the device but not described in detail in this chapter. For detailed information about this module, see [Chapter 5, DSP Subsystem](#).
- Cortex-M3 MPUSS interrupt controller (Cortex-M3 MPU INTC): This module is also called Nested Vectored Interrupt Controller (NVIC) and is integrated within each Cortex-M3 so the different interrupt lines are directly connected to each core. The interrupt mapping is the same for the two cores to facilitate parallel processing. The NVIC supports:
 - 64 external interrupts (in addition to 16 Cortex-M3 internal interrupts), which are dynamically prioritized with 16 levels of priority defined for each core
 - Low-latency exception and interrupt handling
 - Prioritization and handling of exceptions
 - Control of the local power management
 - Debug accesses to the processor core
 - Wake-up generator (WUGEN) module on external interrupts, coming from device peripherals

Figure 17-1 shows the internal interrupt scheme of the device.

Figure 17-1. Interrupt Controllers Overview

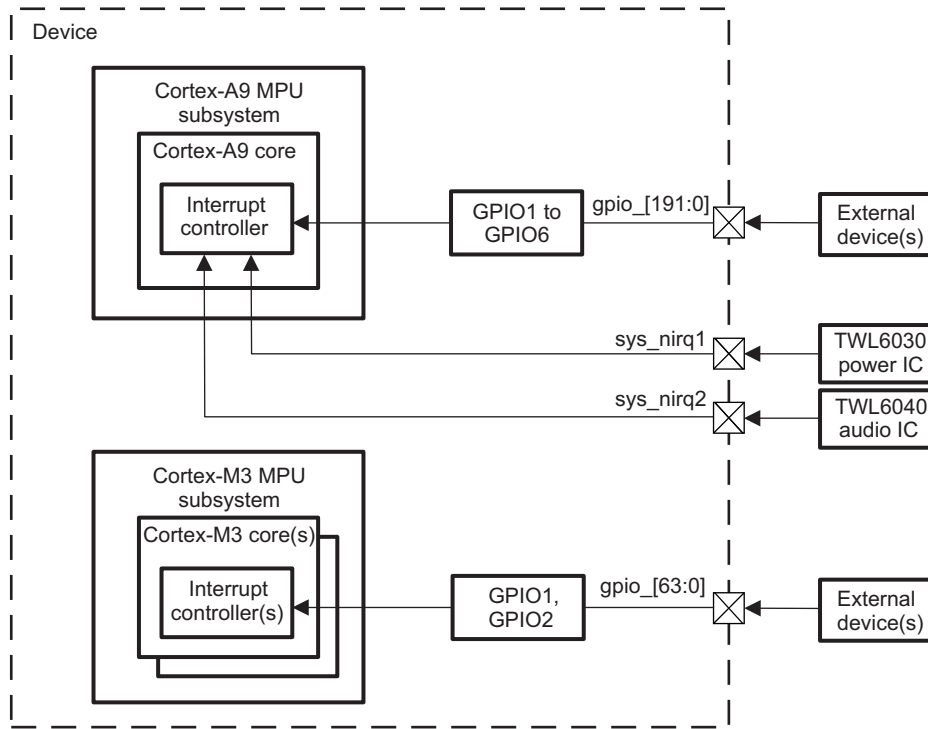

NOTE: For more information about the WUGEN module in the Cortex-A9 MPUSS (including integration, functional and register description), see [Chapter 4, Cortex-A9 MPU Subsystem](#). For more information about the WUGEN module in the Cortex-M3 MPUSS (including integration, functional and register description), see [Chapter 7, Cortex-M3 MPU Subsystem](#).

17.2 Interrupt Controllers Environment

This section describes the INTC application fields from the environment point of view (external connections).

Figure 17-2 shows the relationship between the module and external interrupts.

Figure 17-2. Interrupts From External Devices

intc-002

Table 17-1 describes the I/O signals that can be used by external devices to generate interrupts to the Cortex-A9 MPU INTC or Cortex-M3 MPU INTC.

Table 17-1. Interrupt Controllers I/O Signals

| Signal Name | I/O ⁽¹⁾ | Reset Value | Description | Cortex-A9 MPU INTC | Cortex-M3 MPU INTC |
|----------------|--------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|--------------------|
| sys_nirq1 | I | 1 | TWL6030 power IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC. | x | - |
| sys_nirq2 | I | 1 | TWL6040 audio IC can use this pin to generate a system wake-up event to Cortex-A9 MPU INTC. | x | - |
| gpio_[31:0] | I/O | - | External devices can use GPIO modules to generate interrupts to the Cortex-A9 MPU or Cortex-M3 MPU. There are six dedicated interrupt lines (for GPIO1 to GPIO6) to the Cortex-A9 MPU INTC and two dedicated interrupt lines (for GPIO1 and GPIO2) to the Cortex-M3 MPU INTC. Each GPIO module can generate a single interrupt whenever there is at least one event in any one of the configured 32 GPIO inputs. For more information about GPIO interrupt generation, see Chapter 25, General-Purpose Interface . | x | x |
| gpio_[63:32] | I/O | - | | x | x |
| gpio_[95:64] | I/O | - | | x | - |
| gpio_[127:96] | I/O | - | | x | - |
| gpio_[159:128] | I/O | - | | x | - |
| gpio_[191:160] | I/O | - | | x | - |

⁽¹⁾ I = Input, O = Output

17.3 Interrupt Controllers Integration

The Cortex-A9 MPU INTC is integrated inside the Cortex-A9 MPU core. For more information about Cortex-A9 MPU INTC integration, see [Chapter 4, Cortex-A9 MPU Subsystem Integration](#).

The Cortex-M3 MPU INTC is integrated inside each Cortex-M3 MPU core. For more information about Cortex-M3 MPU INTC integration, see [Chapter 7, Dual Cortex-M3 MPU Subsystem Integration](#).

17.3.1 Interrupts Mapping

NOTE: All device peripherals interrupts (external to the Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems) are active-high, level sensitive.

CAUTION

A single interrupt source can be physically mapped to multiple INTCs (Cortex-A9 MPU, DSP, and Cortex-M3 MPU subsystems). With multiple-mapped interrupts, it is strongly recommended to unmask each interrupt source in only one INTC at a time.

17.3.2 Interrupt Requests to Cortex-A9 MPU INTC

[Table 17-2](#) shows the Cortex-A9 MPU INTC interrupt mapping.

Table 17-2. Cortex-A9 MPU INTC Interrupt Mapping

- (1) Internally generated within the Cortex-M3 MPU subsystem
- (2) Shared with DSP INTC
- (3) Shared with Cortex-A9 MPU INTC
- (4) Shared with DSP and Cortex-A9 MPU INTCs

NOTE: MM_IRQ_0 triggers exception #16 inside the Cortex-M3 core(s).

NOTE: All Cortex-M3 MPUSS internal interrupts are edge interrupts, except the one generated from the MMU (XLATE_MMU_FAULT), which is level interrupt.

17.4 Interrupt Controllers Functional Description

17.4.1 Cortex-A9 MPU INTC Functional Description

Cortex-A9 MPU INTC is configured to have the following interrupt sources:

- 16 Interprocessor interrupts (IPI): ID[15:0]
- 2 private Timer/Watchdog interrupts: ID[30:29]
- 2 legacy nFIQ & nIRQ: one per CPU, bypasses the interrupt distributor logic and directly drives interrupt requests into CPU if used in legacy mode (else treated like other interrupts lines with ID28 and ID31 respectively)
- 128 hardware interrupts: ID[159:32] (rising-edge or high-level sensitive). The interrupt mapping of these interrupts is presented in [Table 17-2, Interrupt Requests to Cortex-A9 MPU INTC](#).

CAUTION

Although the hardware interrupts can be configured to be rising-edge or high-level sensitive in the INTC, the device supports only active-high, level-sensitive configuration.

For more information about the functionality of the Cortex-A9 MPU INTC, see *ARM Cortex-A9 MP Core Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.4.2 Cortex-M3 MPU INTC Functional Description

The Cortex-M3 MPU INTC has the following configuration in the device:

- 64 hardware interrupts/16 levels of priority for each Cortex-M3 core. The interrupt mapping of these interrupts is presented in [Table 17-3, Interrupt Requests to Cortex-M3 MPU INTC](#).
- The calibration register, which is used to reload the SYSTICK timer to generate a fixed interval, is not supported in the Cortex-M3 core within the Cortex-M3 MPUSS. The TENMS field is not available due to the different frequencies during voltage scaling.
- The SYSRESETREQ reset feature is not supported at the Cortex-M3 processor level. Writing to this bit has no effect.

For more information about the functionality of the Cortex-M3 MPU INTC, see *ARM Cortex-M3 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.5 Interrupt Controllers Register Manual

17.5.1 Interrupt Controllers Instance Summary

For information about the Cortex-A9 MPU INTC and Cortex-M3 MPU INTC instances, see [Chapter 4](#), *Cortex-A9 MPU Subsystem* and [Chapter 7](#), *Dual Cortex-M3 Subsystem*.

17.5.2 Cortex-A9 MPU INTC Registers

For information about the Cortex-A9 MPU INTC registers and their description, see *ARM Cortex-A9 MP Core Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

17.5.3 Cortex-M3 MPU INTC Registers

For information about the Cortex-M3 MPU INTC registers and their description, see *ARM Cortex-M3 Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

Control Module

This chapter describes the system control module for the device.

| Topic | Page |
|---------------------------------------------------------|-------------|
| 18.1 Control Module Overview | 3621 |
| 18.2 Control Module Environment | 3623 |
| 18.3 Control Module Integration | 3624 |
| 18.4 Control Module Functional Description | 3628 |
| 18.5 Control Module Programming Guide | 3843 |
| 18.6 Control Module Register Manual | 3852 |

18.1 Control Module Overview

The control module allows software control of the various static modes supported by the device. It is composed of two control submodules: general control module and device (padconfiguration) control module.

The general control module has the following features:

- General status and control
- Hardware observability input/output (I/O) multiplexing
- Standard eFuse logic

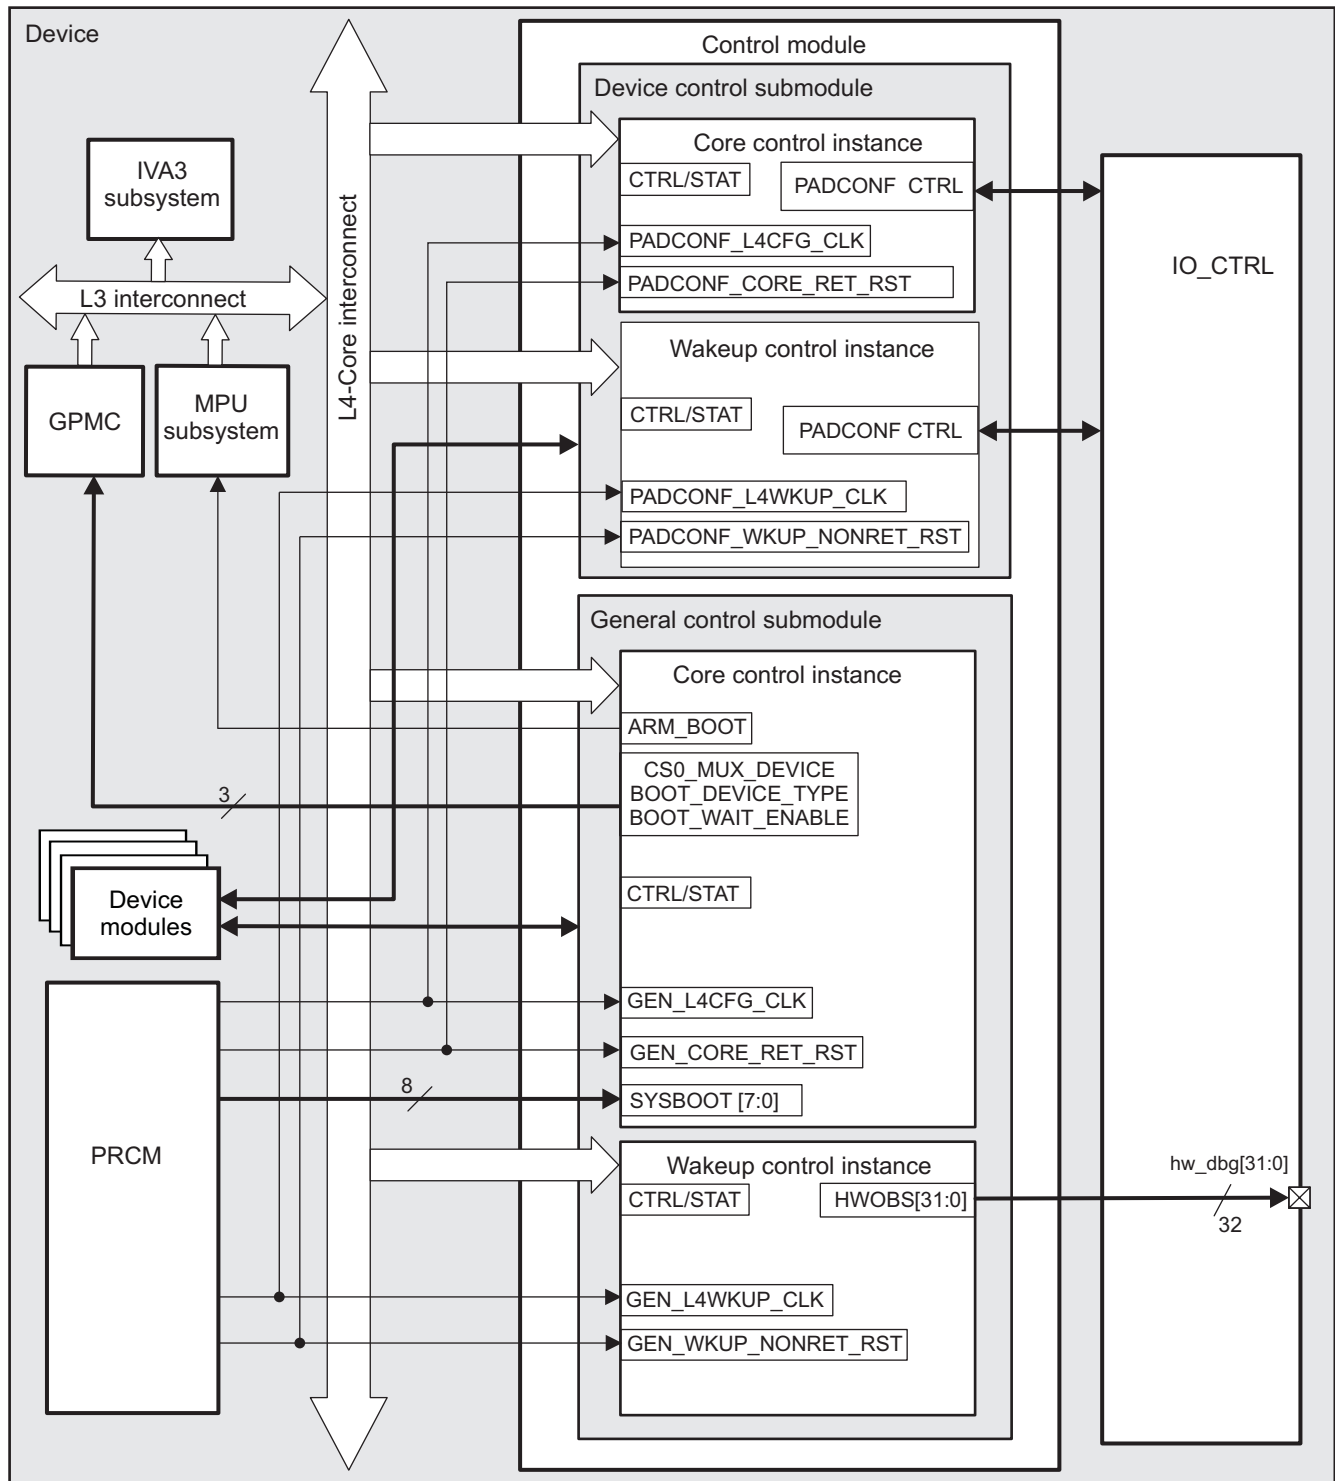

The device control module provides the following features:

- Pad functional I/O multiplexing
- Pad pullup/down configuration
- Pad groups associated signal integrity controls
- Complex I/O configuration
- Analog function control
- Device-specific eFuse registers

Both control submodules are split into two instances: the control core instance within the CORE power domain, and the control wake-up instance within the WKUP power domain. For more information about the four different control module instances, see [Section 18.3, Control Module Integration](#).

[Figure 18-1](#) shows the overview of the control module.

Figure 18-1. Control Module Overview

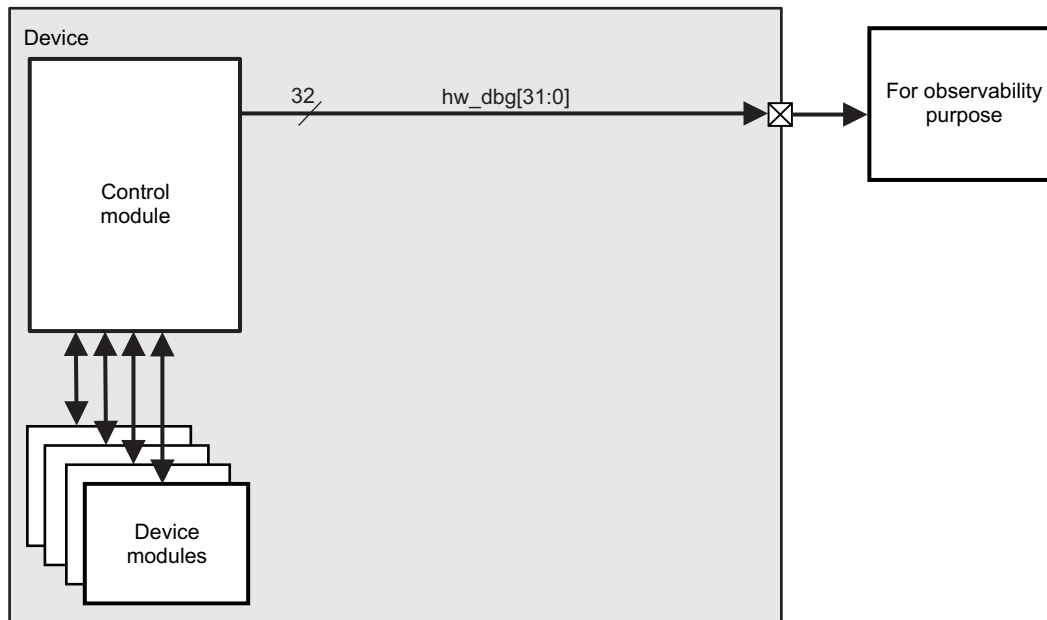

sysctrl-001

18.2 Control Module Environment

The control module controls the multiplexing of device internal module signals routed to the external pins (hw_dbg[31:0]) for hardware debug purposes. For more information, see [Section 18.4.11, Hardware Observability](#), and [Section 18.4.8, PAD Functional Multiplexing and Configuration](#). Using the correct pad configuration, the control module maps these pins at the device boundary to observe the internal signals from the power, reset, and clock management (PRCM) module signals, direct memory access (DMA) requests, and interrupts. [Figure 18-2](#) shows an overview of the control module environment.

Figure 18-2. Control Module Environment

sysctrl-002

18.2.1 Control Module Signals

[Table 18-1](#) lists the control module hardware observability outputs configured to observe device module debug signals. It describes the module signals and specifies their links to functions.

Table 18-1. Control Module I/O Description

| Signal | I/O ⁽¹⁾ | Description | Reset Value ⁽²⁾ |
|--------------|--------------------|-------------------------------------------------|----------------------------|
| hw_dbg[31:0] | O | Internal hardware observability signals 0 to 31 | Hi-Z |

⁽¹⁾ I = Input; O = Output

⁽²⁾ Hi-Z = High impedance

18.3 Control Module Integration

The control module of the device is on the L4-Core interconnect. It consists of four module instances:

- General core control module (SYSCTRL_GENERAL_CORE)
- General wakeup control module (SYSCTRL_GENERAL_WKUP)
- Device core control module (SYSCTRL_PADCONF_CORE)
- Device wakeup control module (SYSCTRL_PADCONF_WKUP)

For more information about the different control module instances, see [Table 18-3](#).

Each of these four module instances has an associated register set and shares one functional clock and one reset signal with the PRCM module. These signals are described in [Table 18-2](#).

Table 18-2. Clocks and Resets

| Clocks | | | | |
|----------------------|-------------------------|--------------------|--------|------------------------------------------------------------------------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SYSCTRL_GENERAL_WKUP | GEN_L4WKUP_CLK | WKUP_L4_ICLK2 | PRCM | L4_WKUP interface/functional clock propagated to the general wakeup control module |
| SYSCTRL_GENERAL_CORE | GEN_L4CFG_CLK | CFG_L4_ICLK | PRCM | L4_CFG interface/functional clock propagated to the general core control module |
| SYSCTRL_PADCONF_WKUP | PADCONF_L4WKUP_CLK | WKUP_L4_ICLK2 | PRCM | L4_WKUP interface/functional clock propagated to the device wakeup control module |
| SYSCTRL_PADCONF_CORE | PADCONF_L4CFG_CLK | CFG_L4_ICLK | PRCM | L4_CFG interface/functional clock propagated to the device core control module |
| Resets | | | | |
| SYSCTRL_GENERAL_WKUP | GEN_WKUP_NONRET_RST | WKUP_PWRON_RST | PRCM | Internal power-on reset affecting general wakeup control module |
| SYSCTRL_GENERAL_CORE | GEN_CORE_RET_RST | CORE_PWRON_RET_RST | PRCM | Internal power-on reset affecting the general core control module |
| SYSCTRL_PADCONF_WKUP | PADCONF_WKUP_NONRET_RST | WKUP_PWRON_RST | PRCM | Internal power-on reset affecting the device wakeup control module |
| SYSCTRL_PADCONF_CORE | PADCONF_CORE_RET_RST | CORE_PWRON_RET_RST | PRCM | Internal power-on reset affecting the device core control module |

The control module is reset by the internal power-on reset (POR), which is active low. The PRCM provides a retention POR signal (CORE_PWRON_RET_RST) duplicated to each of the two core control module instances, and a nonretention POR signal (WKUP_PWRON_RST) duplicated to each of the two wake-up control module instances in the control module. For more information, see [Section 3.5.4](#), *Reset Domains*, in [Chapter 3](#), *Power, Reset, and Clock Management*. The control module does not respond to a warm reset or to an L4-Core reset.

The main sequential logic within the system control module is accessible in a register file through the L4-Core interconnect. The PRCM module provides the CFG_L4_ICLK functional clock signal (L4_CFG clock domain) separately to both of the core control submodules. See [Section 3.6.3.2.4](#), *CM2 Clock Generator* in [Chapter 3](#), *Power, Reset, and Clock Management*, for more information about this signal.

The PRCM module also supplies the WKUP_L4_ICLK2 functional clock signal (L4_WKUP -clock domain) to both of wake-up control module instances. See [Section 3.6.3.1](#), *PRM Clock Source*, in [Chapter 3](#), *Power, Reset, and Clock Management*, for more information about this signal.

The PRCM module latches the sys_boot [7:0] pad signals at power-on reset and exports them as vector to the SYSBOOT[7:0] input of the General Core Control module. It is scanned in the CONTROL_STATUS[7:0] SYS_BOOT bit field. For more information, see [Section 27.2.4.2](#), *Booting Device Order Selection*, and [Section 27.2.4.1](#), *Clock Source Selection*.

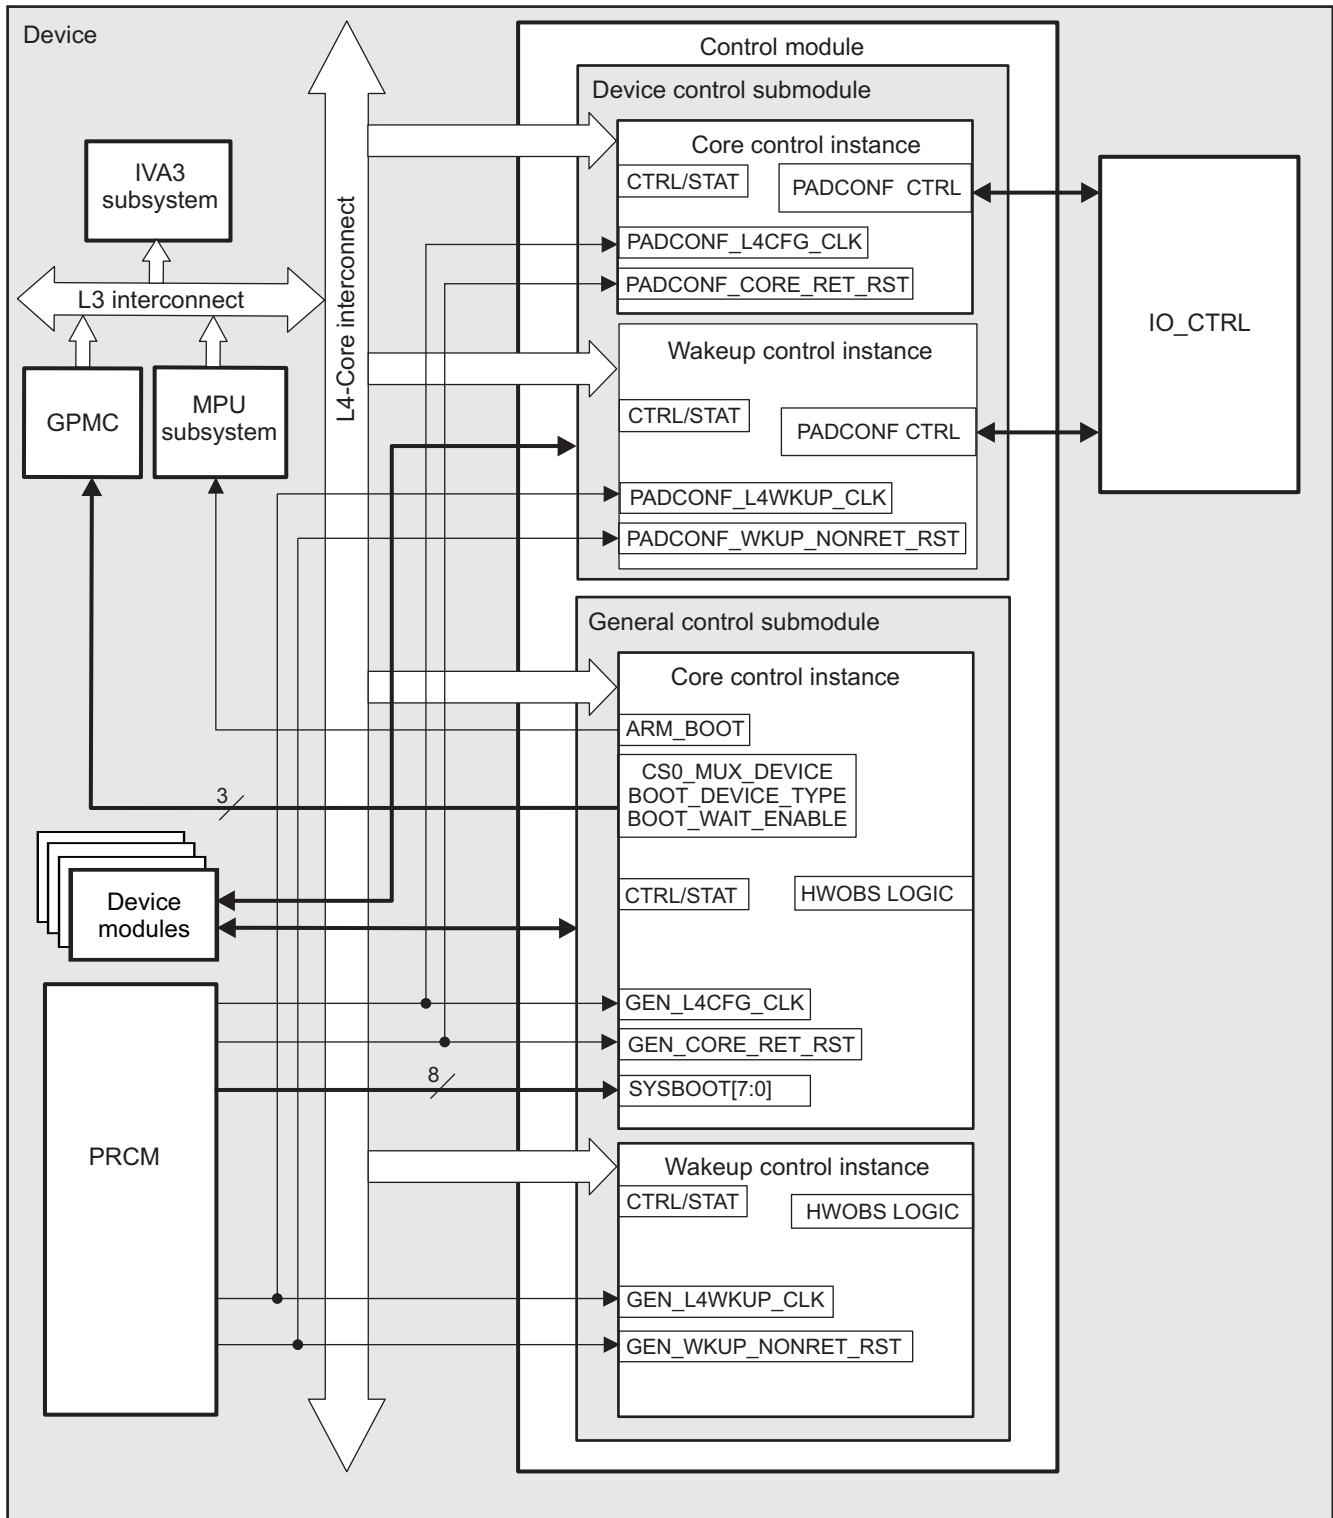

The signal integration of the control module features:

- No IDLE hardware handshake

- No STANDBY hardware handshake
- No SAVE and RESTORE hardware handshake
- No Wake-up request generation
- No DMA request generation
- No interrupt request (IRQ) generation
- Two functional clocks, one within the CFG and the other within WKUP clock domains
- One retention and one nonretention internal power-on based resets

[Figure 18-3](#) summarizes the integration of the module in the device.

Figure 18-3. Control Module Integration

sysctrl-003

Table 18-3 lists the integration attributes.

Table 18-3. Integration Attributes

| Module Instance | Attributes | |
|----------------------|--------------|--------------|
| | Power Domain | Interconnect |
| SYSCTRL_GENERAL_WKUP | PD_WKUP | L4_WKUP |
| SYSCTRL_GENERAL_CORE | PD_CORE | L4_CFG |
| SYSCTRL_PADCONF_WKUP | PD_WKUP | L4_WKUP |
| SYSCTRL_PADCONF_CORE | PD_CORE | L4_CFG |

Software sets the configuration registers to the desired values depending on the configuration of the requested device. Static device configuration registers can be set by software at any time and are effective immediately.

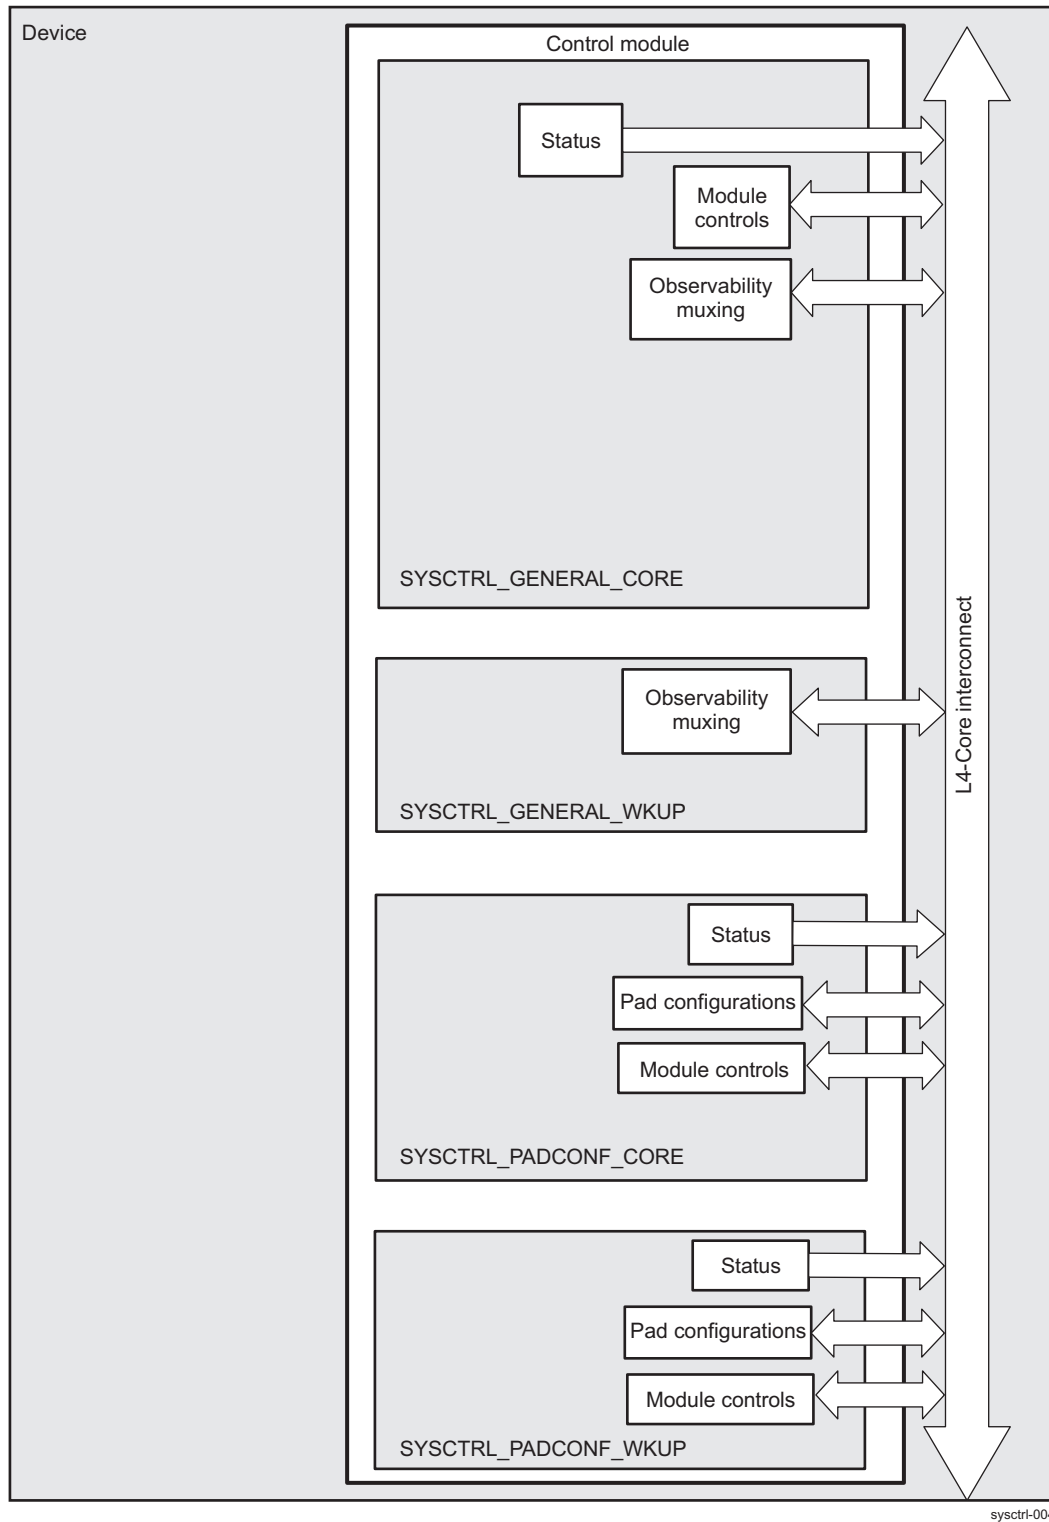

18.4 Control Module Functional Description

18.4.1 Control Module Block Diagram

The control module controls the settings of various device modules through register configuration and internal signals. It also controls the pad configuration, pin functional multiplexing, and the routing of internal signals (such as PRCM signals or DMA requests) to output pins configured for hardware observability.

[Figure 18-4](#) is the control module block diagram.

Figure 18-4. Control Module Block Diagram

Each control submodule primarily implements a bank of registers accessible (read/write) by the software along with some read-only registers carrying status information.

Read/write registers available in the general control module can be divided into the following classes:

- Hardware observability registers (32-bit read/write register)

- Status and configuration registers
- Boot registers
- eFuse ROM registers
- Miscellaneous functional registers

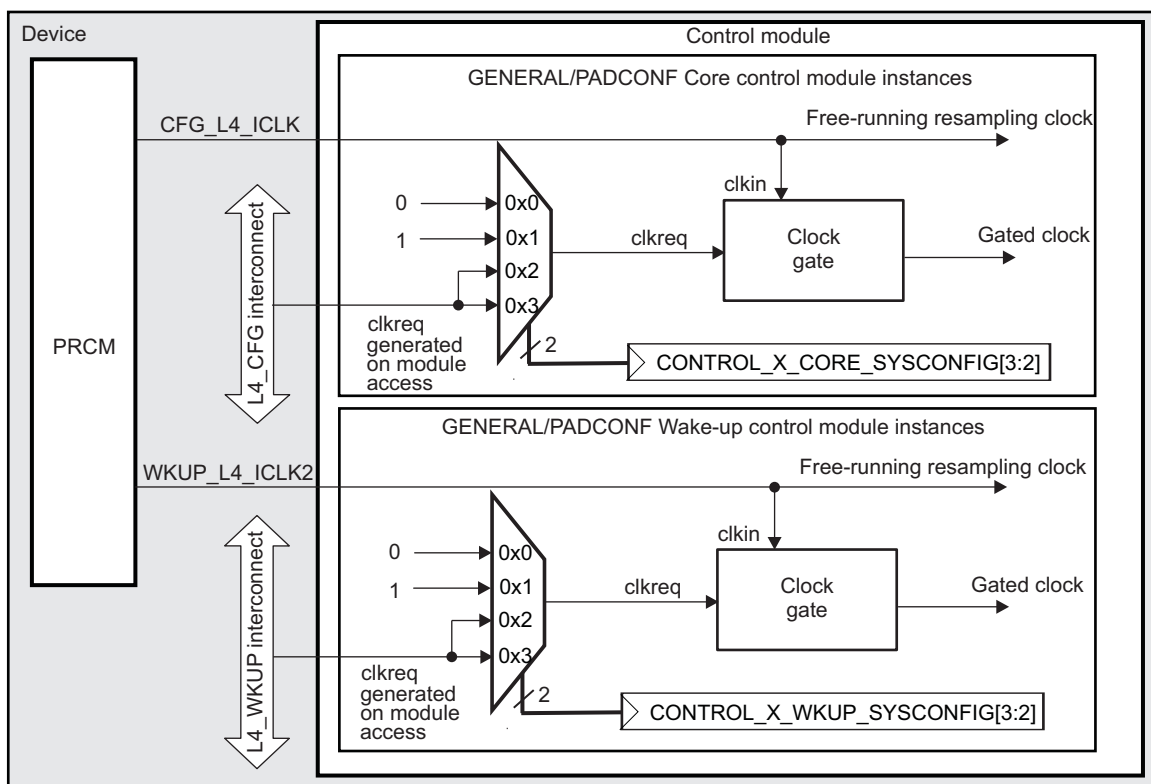

Read/write registers available in the device(padconfiguration) control module can be divided into the following classes:

- Pad configuration registers (32-bit registers, one register for two pads)
- Pad groups (not individual per pad) associated registers for signal integrity parameters control (32-bit read/write registers)
- I/O cells associated specific control registers
- Device-specific status and configuration registers
- Miscellaneous functional registers

18.4.2 Control Module Clock Configuration

Figure 18-5 shows the control module internal clock distribution schema. Each CFG_L4_ICLK and WKUP_L4_ICLK2 source clock is internally distributed into two clock paths: the first one directly mirrors the source clock and is an always-running clock. It is used to synchronize and resample some of the module inputs. The other clock path can be internally gated within the module.

Figure 18-5. Control Module Internal Clock Paths

sysctrl-005

The clock-gating strategy is selected through the CONTROL_SYSCONFIG[3:2] IP_SYSCONFIG_IDLEMODE bit field available in each of the four control module instances. The different possibilities for clock management are described in Table 18-4. There are no PRCM software controls for the control module clocks. There are, however, clock activity status bits in the PRCM module. See Section 3.6.15.2, *Clock Domain Modes*, and Section 3.6.4, *CD_WKUP Clock Domain*, in Chapter 3, *Power, Reset, and Clock Management*.

Table 18-4. Internal Clock Gating Options

| Feature | CONTROL_SYSCONFIG[3:2] IP_SYSCONFIG_IDLEMODE value | Description |
|------------------------|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------|
| Local clock control | 0b00 | Clock is manually gated. |
| Local clock control | 0b01 | Clock is manually enabled. |
| Local clock autogating | 0b10, 0b11 | Clock is automatically gated when there is no access to the control module through L4-interconnect. |

18.4.3 Control Module Software Reset

The control module is not sensitive to software reset.

18.4.4 Control Module Power Management

18.4.4.1 Retention

The general- and device core control module instances are fully built with retention flip-flop (RFF) and are powered in the CORE domain, so they can be in active or retention mode. The core instances lose their content when the CORE power domain is in off mode. In contrast to the core control instances, the control wake-up instances are always powered and active. [Section 3.9, Device Low-Power States](#), in [Chapter 3, Power, Reset, and Clock Management](#), provides more information about the device low-power states.

18.4.4.2 Power Management Protocols

The control module, which is slave on the L4 interconnect, does not support standby or idle mode protocols.

18.4.4.3 Save-and-Restore Mechanism

The control core module instances lose their contents when the CORE power domain is in off mode. To prevent this, before going to off mode, the core register context is copied by software into a dedicated SAR_RAM sitting in the WKUP voltage domain. The save-and-restore (SAR) mechanism, controlled by the PRCM module, allows them to restore registers to the value present before going to off mode. Thus, core domain registers will have a correct configuration/state immediately after core power is on again without requesting a software operation to reconfigure them.

Because the SAR mechanism is managed by software-accessible registers, no hardware-specific requirements exist. For more information about SAR, see [Section 3.9.3, Device Off State Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

18.4.5 Hardware Requests

The control module does not generate interrupt, DMA, or wake-up requests.

18.4.6 Control Module Initialization

The control module responds only to the internal POR and device type. At power on, reset values for the registers define the *safe state* for the device. In the initialization mode, only modules to be used at boot time are associated with the pads. Other module inputs are internally tied and output pads are turned off. After POR, software sets the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. For more information, see [Chapter 27, Initialization](#).

General-purpose (GP) devices include features that are inaccessible or unavailable. These inaccessible registers define the default or fixed device configuration or behavior.

The [CONTROL_STATUS\[7:0\]](#) SYS_BOOT bit field reflects the state of the sys_boot pins captured at POR in the PRCM module.

18.4.7 Control Module Instances

18.4.7.1 General Core Control Module Instance

The SYSCTRL_GENERAL_CORE instance contains most of the control logic providing hardware observability features for different DPLL clockout and DPLL-specific signals, DMA requests, IRQs, and other internal hardware signals. The general core control provides the system boot decoding logic and has control over the standard eFuse settings. The system configuration registers, specific function controls, some peripheral control and status registers are also mapped there.

The register sets available within the SYSCTRL_GENERAL_CORE are:

- Observability control registers:
 - [CONTROL_HWOBS_CONTROL](#)
 - [CONTROL_DEBOBS_FINAL_MUX_SEL](#)
 - [CONTROL_CONF_SDMA_REQ_SELx](#)
 - [CONTROL_CONF_CLK_SELx](#) (where x = 0 to 2)
 - [CONTROL_CONF_DPLL_X_SEL](#) (where X is FREQLOCK, TINITZ, PHASELOCK, TENABLE, TENABLEDIV, BYPASSACK, IDLE)
- Part of the debug view channel selection registers: [CONTROL_CORE_CONF_DEBUG_SEL_TST_X](#)
- MMU address translation related registers: [CONTROL_CORTEX_M3_MMUADDRTRANSLTR](#) and [CONTROL_CORTEX_M3_MMUADDRLOGICTR](#)
- Standard fuse registers: [CONTROL_STD_FUSE_X](#)
- Clock gating configuration register: [CONTROL_GEN_CORE_SYSCONFIG](#)
- Control status register: [CONTROL_STATUS](#)
- Peripheral controls:
 - [CONTROL_TEMP_SENSOR](#)
 - [CONTROL_DSS_CONTROL](#)
 - [CONTROL_USBOTGHS_CONTROL](#)
 - [CONTROL_LDOSRAM_MPU_VOLTAGE_CTRL](#)
 - Etc.

18.4.7.2 General Wakeup Control Module Instance

The registers associated with this module are:

- Clock gating configuration register: [CONTROL_GEN_WKUP_SYSCONFIG](#)
- Register with spare bits: [CONTROL_OCPREG_SPARE](#)
- Part of the debug view channel selection registers: [CONTROL_WKUP_CONF_DEBUG_SEL_TST_X](#)

18.4.7.3 Device Core Control Module Instance

The SYSCTRL_PADCONF_CORE instance provides the device-specific pad control features such as pullup/down I/O configuration and pad functional multiplexing. Wake-up control/status features are also subject of the device core control.

The registers associated with this module are:

- Clock gating configuration register:
- Different peripheral pad mode configuration and wake-up status/configuration registers:
 - [CONTROL_PADCONF_CORE_SYSCONFIG](#)
 - [CONTROL_CORE_PAD0_X_PAD1_Y](#)
 - [CONTROL_PADCONF_WAKEUPEVENTx](#)
 - [CONTROL_PADCONF_GLOBAL](#)
 - [CONTROL_SMARTxIO](#)

- And so on.
- Peripheral pad voltage-level control registers: CONTROL_PADCONF_MODE
- Miscellaneous controls for different device interface modules: CONTROL_X registers (including CONTROL_EFUSE registers)

18.4.7.4 Device Wakeup Control Module Instance

Configuration registers for all pads linked to the wake-up voltage domain are in the wake-up device control module. The registers instantiated here are:

- Clock gating configuration register: [CONTROL_PADCONF_WKUP_SYSCONFIG](#)
- CONTROL_WKUP_PAD0_X_PAD1_Y registers for configuring FREF clock oscillator pads, reset signals, and power mode pad configurations

NOTE: SYSCTRL_PADCONF_X alias notifies a device control module Instance.

[Table 18-112](#) shows the memory size and base addresses assigned to the different control module instances

18.4.8 Pad Functional Multiplexing and Configuration

After POR, software must set the pad functional multiplexing and configuration registers to the desired values according to the requested device configuration. The configuration is controlled by pads or by a group of pads. Each configurable pin has its own configuration register for pullup/down control and for the assignment to a given module.

Two sets of 32-bit registers provide the pad functional multiplexing and configuration feature of the control module. The first set of registers (CONTROL_CORE_PAD0_X_PAD1_Y) configures the pads in the CORE power domain. The second set of registers (CONTROL_WKUP_PAD0_X_PAD1_Y) configures pads in the WKUP power domain.

The pad configuration as defined in this module is used in the IO_CTRL logic along with the gating and protection features. The gating feature is implemented for the output pads. The protection feature is implemented for input lines. These features implement additional control and multiplexing capabilities hard-wired in the IO_CTRL logic and driven by the internal device state and/or logic.

The gating feature allows forcing of an output pad to a fixed value (Z, pullup, pulldown, 1, 0) or to a given internal signal. Each gating command is defined with a logic equation and the output state/value to be set on the pad when the logic equation is "True."

The protection feature provides control on each input line of the module when no pad is assigned to this input (protected value). When POR is released, the value on the pad is driven by the default configuration of the control module. This configuration is usually aligned with the default value selected on the I/O cell. The protected value can be logical level (0 or 1) or a signal from a pad; it is selected when none of the pad_x.MuxMod selects a device input.

Each 32-bit pad configuration register controls two pads: the first pad is controlled by the 16-least significant bits (LSBs), and the second pad is controlled by the 16 most-significant bits (MSBs); hence, one pad configuration register provides control for two different pins. After POR, software sets the pad functional multiplexing and configuration registers to the requested device pad configurations. Data written in these registers directly commands the multiplexing of the pad configuration logic. [Figure 18-6](#) describes the 16-bit-wide pad configuration register field associated with each pin.

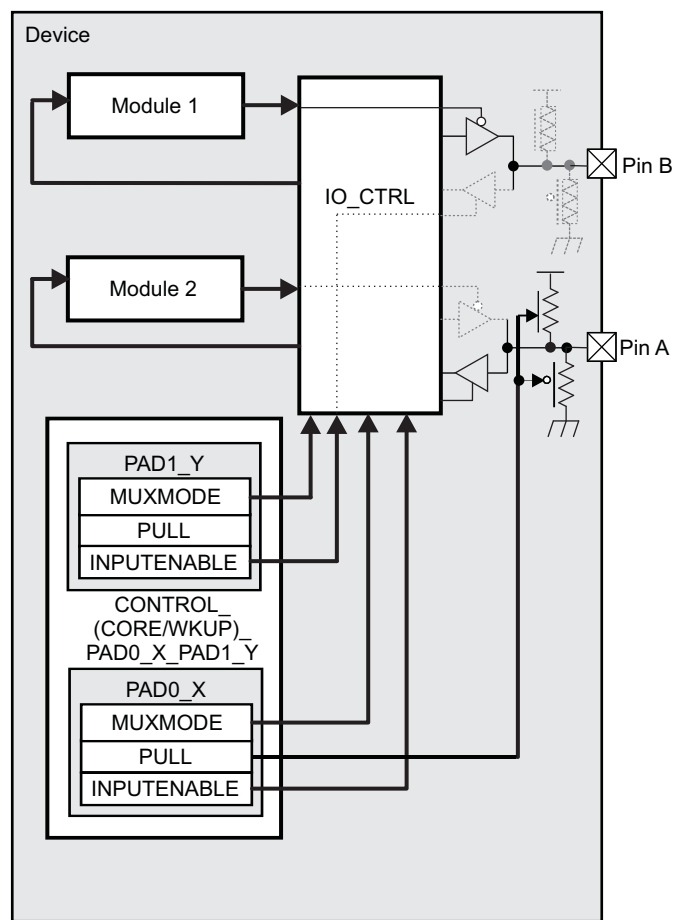

CAUTION

The OFFOUTENABLE and OFFOUTVALUE bits are functional only if the pad configuration supports output mode on at least one MUXMODE. For a pad that supports only the input feature, the OFFOUTENABLE and OFFOUTVALUE bits cannot be configured (they are don't care and read always returns 0).

NOTE: Because off mode affects only the pads in the CORE domain, OFFMODE-related bits are not present in the padconfiguration registers of the WKUP power domain .

Figure 18-7 shows the pad configuration function when off mode is inactive. For more information about off mode, see Section 18.4.8.4, *Off Mode*.

Figure 18-7. Pad Configuration Diagram

The I/O pads are software-controlled by:

- Writing to the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers in the device control module for I/O and pullup/down configuration.
- Writing to the GPIOi.GPIO_OE registers in the GPIO module for I/O configuration.

For more information about how to configure the I/O pads, see Section 18.5.1.2.5, *Pad Configuration Programming Points*.

For more information about the GPI/O module, see Section 25.4.8, *General-Purpose Interface Data Input/Output Capabilities*.

NOTE: For the proper functioning of the following modules, the INPUTENABLE bit in the corresponding pad configuration register must be set to 1 for pads configured to drive output clocks:

- GPMC
- I2Ci
- MMCi
- HSUSB HOST
- McPDM

NOTE: For a correct configuration of each pin direction (input, output, bidirectional), the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y and the GPIOi.GPIO_OE registers must be written.

NOTE: Software INPUTENABLE controls are not available for the Ipddr21_x, Ipddr22_x, usbb1_hsic_x, and usbb2_hsic_x pads. Once their buffers are enabled they are always bidirectional. For more information, see [Section 18.4.12.9.2, High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings](#).

[Table 18-5](#) lists the bit directions of the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y registers.

Table 18-5. Bit Meanings for CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y Registers

| Pad Configuration Bit | Bit Meaning | |
|-----------------------|----------------------------------|----------------------------------|
| | 0 | 1 |
| PULLUDENABLE | Not activated | Activated |
| PULLTYPESELECT | Pulldown | Pullup |
| INPUTENABLE | Input enable signal is inactive. | Input enable signal is active. |
| OFFMODEENABLE | Off mode values are invalid. | Off mode values are valid. |
| OFFMODEOUTENABLE | Output | Input |
| OFFMODEOUTVALUE | Low | High |
| OFFMODEPULLUDENABLE | Not activated | Activated |
| OFFMODEPULLTYPESELECT | Pulldown | Pullup |
| WAKEUPENABLE | Disable I/O wake-up function. | Enable I/O wake-up function. |
| WAKEUPEVENT | Wake-up event is not detected. | Wake-up event is detected. |
| MUXMODE bits | See Table 18-6 . | See Table 18-6 . |

18.4.8.1 Mode Selection

[Table 18-6](#) lists the multiplexing modes and settings.

Table 18-6. Mode Selection

| MUXMODE | Selected Mode |
|---------|-----------------------|
| 0b000 | Primary mode = Mode 0 |
| 0b001 | Mode 1 |
| 0b010 | Mode 2 |
| 0b011 | Mode 3 |
| 0b100 | Mode 4 |
| 0b101 | Mode 5 |
| 0b110 | Mode 6 |
| 0b111 | Safe mode = Mode 7 |

The MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers defines the multiplexing mode applied to the pad. Modes are referred to by their decimal (from 0 to 7) or binary (from 0b000 to 0b111) representation. Functional modes are defined from 0b000 to 0b110; mode 0b111 is referred to as the safe mode.

For most pads, the reset value for the MUXMODE field in the CONTROL_CORE_PAD0_X_PAD1_Y and CONTROL_WKUP_PAD0_X_PAD1_Y registers is 0b111. The exceptions are pads to be used at boot time to transfer data from selected peripherals to the external flash memory.

Mode 0 is the primary mode. When mode 0 is set, the function mapped to the pin corresponds to the name of the pin.

Mode 1 to mode 6 are possible modes for alternate functions. On each pin, some modes are used effectively for alternate functions, while other modes are unused and correspond to no functional configuration.

The safe mode (mode 7) avoids any risk of electrical contention by configuring the pin as an input with no functional interface mapped to it. The safe mode is used mainly as the default mode for all pins containing no mandatory interface at the release of POR.

NOTE: When a pad is set into a mux mode that is not defined by pin multiplexing, this pad is set undriven (Hi-Z) with potential pullup/down.

For more information about the configurable mode on each pin, see [Table 18-9](#) and [Table 18-8](#).

NOTE: Pad names are signal names available in mode 0.

18.4.8.2 Pull Selection

There is no automatic gating control to ensure that internal weak pulldown/pullup resistors on a pad are disconnected whenever the pad is configured as output. If a pad is always configured in output mode, it is recommended for user software to disable any internal pull resistor tied to it, to avoid unnecessary consumption.

Table 18-7. Pull Selection

| PULL | | Pin Behavior |
|----------------|--------------|-------------------------------------|
| PULLTYPESELECT | PULLUDENABLE | |
| 0b0 | 0b0 | Pulldown selected but not activated |
| 0b0 | 0b1 | Pulldown selected and activated |
| 0b1 | 0b0 | Pullup selected but not activated |
| 0b1 | 0b1 | Pullup selected and activated |

For more information about the pull available on each pin, see [Table 18-8](#) and [Table 18-9](#).

NOTE: Software controls for internal active mode pullups and pulldowns on the lpddr21_x and lpddr22_x pads are available in the [CONTROL_LPDDR2IO1_0](#) through [CONTROL_LPDDR2IO1_2](#) and [CONTROL_LPDDR2IO2_0](#) through [CONTROL_LPDDR2IO2_2](#) registers, respectively.

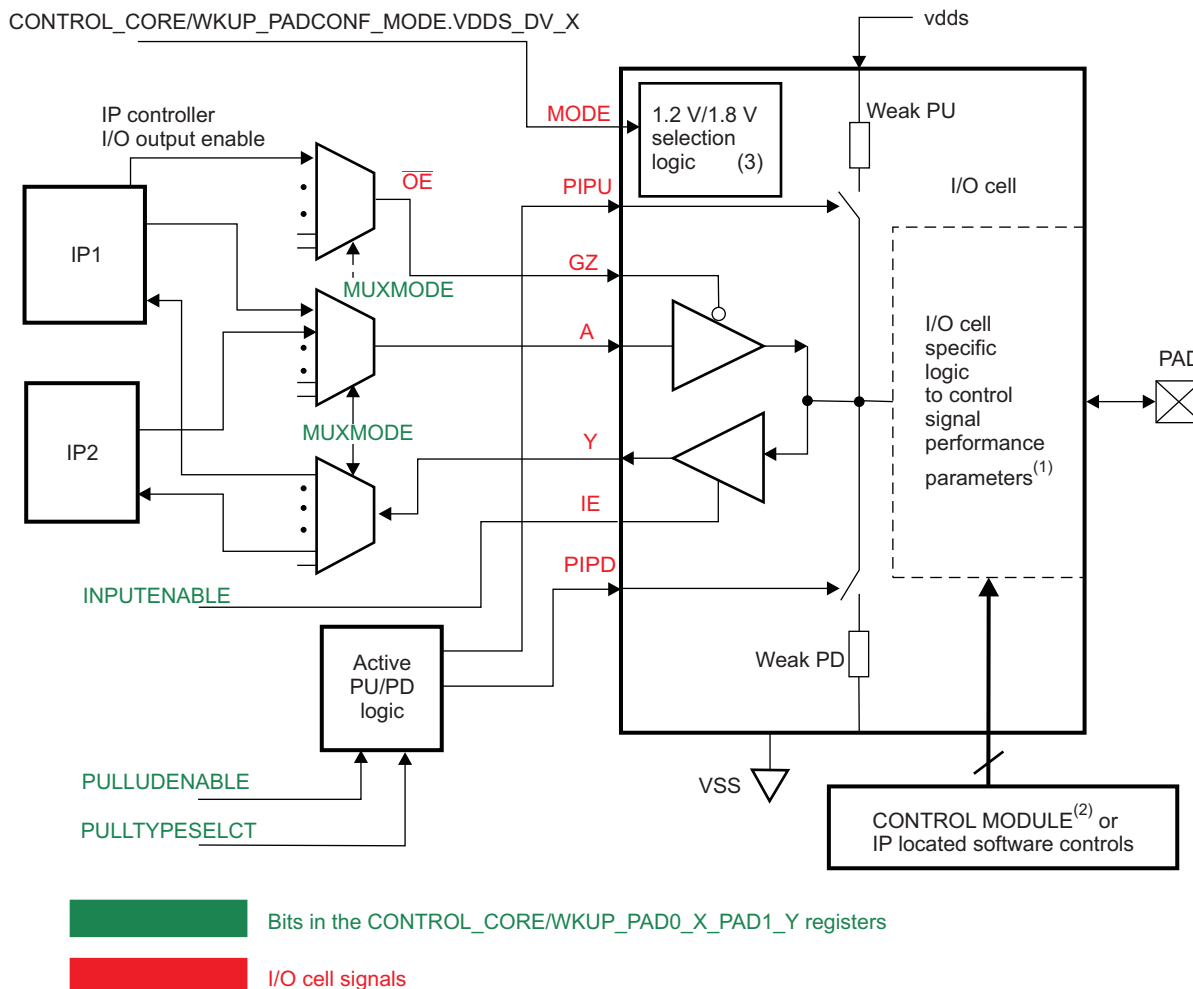

Software controls for internal active mode pullups and pulldowns on the usbb1_hsic_x and usbb2_hsic_x pads are available in the [CONTROL_USBB_HSIC](#) register.

For more information, see [Section 18.4.12.9.2, High-Speed I/O Buffers With Impedance, Slew Rate, and Weak Driver Settings](#).

18.4.8.2.1 Generic Pad Configuration Bit Fields vs I/O Cell Mapping

Figure 18-8 provides a generic view of the relations between the pad configuration controls and I/O cell functions for a pad configured in active mode.

Figure 18-8. Active Mode Pad Configuration Bit Fields vs I/O Cell Mapping

sysctrl-022

- (1) [Section 18.4.12.9, Signal Integrity Parameter Control Registers With Pad Group Assignment](#), summarizes the I/O cell signal performance settings. For more information about the controlled I/O cell electrical parameters and interdependency considerations, see the device data manual.
- (2) For information about the mapping of software controls in the control module versus different device pads, see [Section 18.4.12.9.9, Device Interfaces Signal Group Controls Mapping](#). For more information about interface-specific signal parameter settings, see the device data manual.
- (3) The `CONTROL_CORE/WKUP_PADCONF_MODE.VDDS_DV_x` bit is available for each I/O that is part of the dual-voltage domain group x. For more information about 1.2-V/1.8-V dual-voltage domain I/Os, see the device data manual. For more information about peripheral dual-voltage software controls versus pad group mapping, see [Section 18.4.12.10, Dual-Voltage-Supplied Peripheral Controls](#).

NOTE: Dynamic switching between 1.2-V and 1.8-V voltage modes on dual-voltage peripheral I/Os is not allowed.

18.4.8.3 Pad Multiplexing Register Fields

Table 18-8 and Table 18-9 provide for each pad configuration register field the address offset and associated signal name for each multiplexing mode (as set by the MUXMODE bit field). Mode 0 is always defined. Modes with no signal name are undefined for the given pad. For more information about default pad configuration settings (POR values) for pads in the CORE power domain, see Section 18.6.7, *SYSCTRL_PADCONF_CORE Register Description*; for pads in the WKUP power domain, see Section 18.6.9, *SYSCTRL_PADCONF_WKUP Register Description*.

NOTE:

- Table 18-8 lists the pad configuration registers instantiated in the WKUP power domain that drive the pads in the WKUP power domain. Table 18-9 lists the pad configuration registers instantiated in the CORE power domain that drive the pads in the CORE power domain.
 - In Table 18-8 and Table 18-9, an empty cell indicates that the mode or pull is not available for this pin.
-

⁽¹⁾ For the pad configuration registers which multiplexing has only one signal set (available in muxmode 0), the MUXMODE bitfield is not implemented, and is described as RESERVED. Software must keep this bit field at its default (Power-on Reset) value.

⁽²⁾ This pad is built on an I/O cell of the extended-drain type, which can be configured to operate within the 1.8-V (standard) or 3.0-V (high) I/O power supply voltage range. A PBIAS cell, which acts as a level shifter, is connected to the extended-drain I/O cell of this pad to appropriately bias its voltage according to the externally applied I/O power supply voltage. To ensure I/O safe operation at 1.8 V or 3.0 V and desired signal performance, the extended-drain I/O cell and its corresponding PBIAS cell must be appropriately configured by software prior to signal selection on the pad, regardless of the signal multiplexing mode. For more details on extended-drain I/O cell and PBIAS cell descriptions and settings, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#), and [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

⁽²⁾ This pad is built on an I/O cell of the extended-drain type, which can be configured to operate within the 1.8-V (standard) or 3.0-V (high) I/O power supply voltage range. A PBIAS cell, which acts as a level shifter, is connected to the extended-drain I/O cell of this pad to appropriately bias its voltage according to the externally applied I/O power supply voltage. To ensure I/O safe operation at 1.8 V or 3.0 V and desired signal performance, the extended-drain I/O cell and its corresponding PBIAS cell must be appropriately configured by software prior to signal selection on the pad, regardless of the signal multiplexing mode. For more details on extended-drain I/O cell and PBIAS cell descriptions and settings, see [Section 18.4.9, Extended-Drain I/O and PBIAS Cell](#), and [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

The off mode I/O pads wake-up scheme is enabled by setting the PRM_IO_PMCTRL[16] GLOBAL_WUEN bit from PRCM module. The wake-up scheme status is transmitted by the WKUP_ENABLE signal. The wake-up event detection capability of each I/O pad of the device is individually enabled or disabled by writing the CONTROL_CORE_PAD0_X_PAD1_Y[30,14] and CONTROL_WKUP_PAD0_X_PAD1_Y[30,14] WAKEUPENABLE bits.

Figure 18-10. Wake-Up Event Detection Overview

NOTE: When wake-up detection is enabled for a pad, the pad must be configured as input to avoid contention between the device output buffer and an external driver. If this pin is already configured as an input in active mode, hardware automatically retains the same input state; no software action is required.

If this pin is configured as an output in active mode, the off override function must be enabled to set the pin as an input during off mode: in the CONTROL_(CORE/WKUP)_PAD0_X_PAD1_Y register, set the OFFMODEENABLE bit to 0x1 to enable the off override function, and set the OFFMODEOUTENABLE bit to 0x1 to switch this pin to input mode.

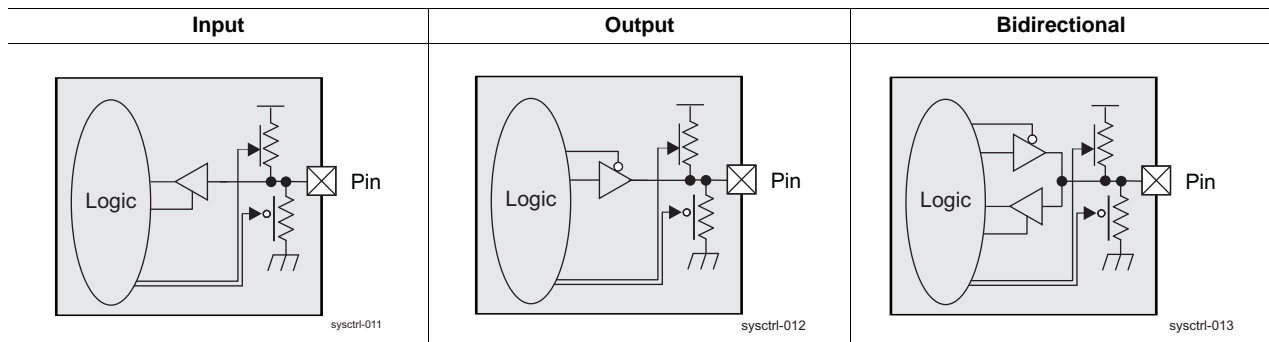

NOTE: Regardless of whether the INPUTENABLE bit is set high or low during active mode, to enable wake-up detection for a pad, user software must set the WAKEUPENABLE bit to 0x1. It is recommended to apply pullup/down resistors at the pad to avoid spurious wake-up detection. User software can optionally enable the pad off-mode internal pullup/down resistors through the appropriate setting of the OFFMODEPULLUDENABLE and OFFMODEPULLTYPESELECT bits in the corresponding pad configuration register.

The registers [CONTROL_PADCONF_WAKEUPEVENT_0](#) through [CONTROL_PADCONF_WAKEUPEVENT_6](#) are dedicated 32-bit registers for a separate capture of the WAKEUPEVENT from different pads. Duplication of the CONTROL_CORE_PAD0_X_PAD1_Y[31,15] and CONTROL_WKUP_PAD0_X_PAD1_Y[31,15] wake-up event bits inside these seven additional registers helps reduce the software latency in identifying which pad has triggered a wake-up event.

18.4.8.4.2 I/O Power Optimization

To optimize I/O power, it is important to avoid unconnected or incorrectly pulled pins. According to the type of pins, the way to reduce power consumption can differ. [Table 18-10](#) shows the three available pin (or ball) types.

Table 18-10. Pin Types

The configuration differs according to the I/O cell types. The following advices can be useful to avoid extra current leakage:

- For input pins, use a pullup/down when possible.
- For output pins, check existing pulls to avoid conflicts.
- For bidirectional pins, reconfigure the pin as an output driving 0 when possible.

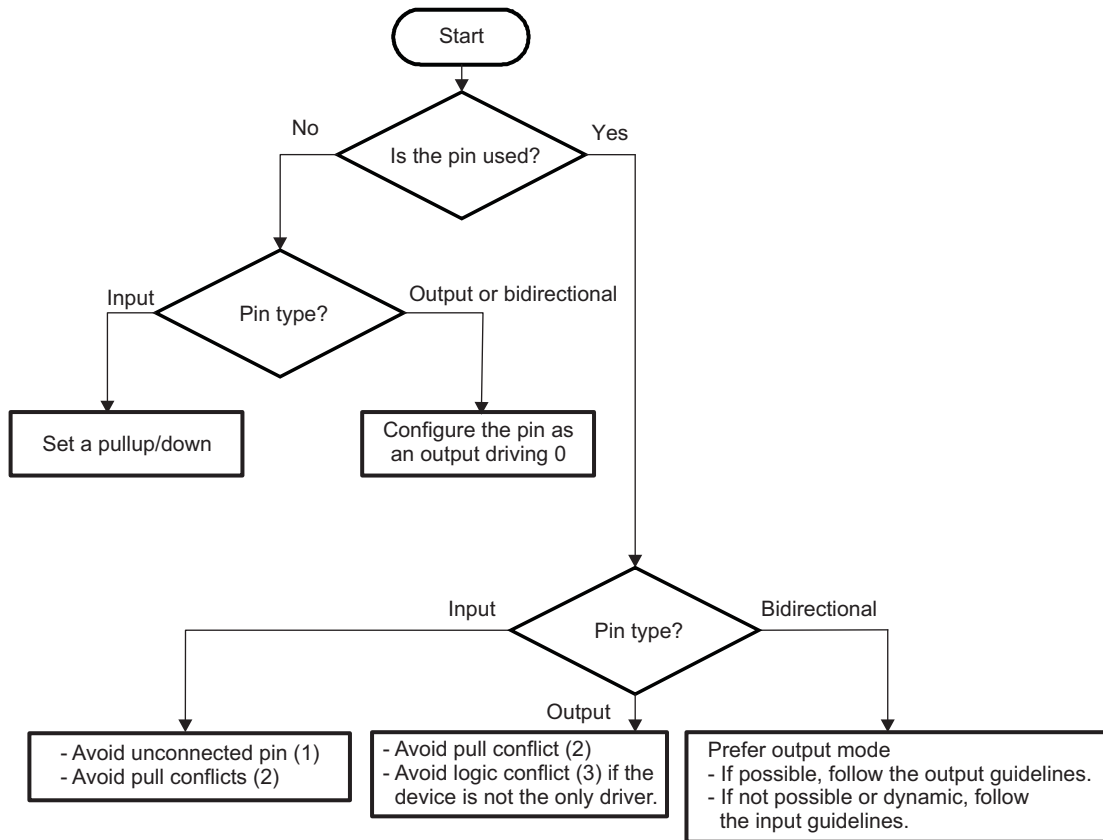

NOTE: If the pad is always configured in output mode, it is recommended for software to disable the internal pull by programming the I/O pad configuration register of the corresponding control module.

NOTE: If a device pad is left unconnected, but power is supplied to the I/O, or the pad is used only as an output during the lifetime of the application, it is recommended to keep its corresponding padconfiguration bit `CONTROL_CORE/WKUP_PAD0_X_PAD1_Y.INPUTENABLE` set to 0b0. This keeps the input buffer disabled and reduces static current consumption.

Some I/O configurations involve modifications during the software setup of I/Os and sometimes require several hardware updates.

[Figure 18-11](#) shows how to optimize the power consumption of pads.

Figure 18-11. I/O Power Optimization Flow Chart

sysctrl-014

The following notes give additional explanation about the pin configuration.

1. To avoid unconnected pins, the configuration depends on its use:
 - If the pin is not driven externally, a pullup/down is required.
 - Otherwise, a pullup/down is not necessary.
2. Pull conflicts occur when different pulls are on the same line. To correctly configure the pin, avoid external and internal pull together.
3. Logic conflicts consist in different electrical levels at the same time on one line. This can occur when several devices are connected to the same line. The two possible cases are:
 - If no external device drives the line, configure the pin to drive a 0.
 - If another device drives the line, either the same value must be driven or the pin must be disconnected (high-impedance state [Hi-Z]).

NOTE: It is advised to use Hi-Z logical state on the device or the external component when the line is driven by both components.

For unconnected device pads, `safe_mode` pad configuration is recommended if available. [Table 18-11](#) summarizes recommendations for the configuration of unconnected pads (in terms of mux mode, input, and output buffer states) for all cases, including those where `safe_mode` configuration is not available.

Table 18-11. Recommended Configuration For Unconnected Device Pads

| Pad MuxMode Set Features | | | Power-on reset default configuration | | Recommended Unconnected Device Pad Configuration | | | | |
|--------------------------|--------------------------|----------------------------------------------|--------------------------------------|--------------------------|--------------------------------------------------|-----------|------------------------|-------------------------|------------------------------|
| Safe Mode Available? | GPIO Function Available? | More Than One (Non-GPIO) Function Available? | Multiplexed Signal Direction at Pad | Pad State ⁽¹⁾ | Multiplexed Signal Direction at Pad | Pad State | Input Buffer Disabled? | Output Buffer Disabled? | MUX Function Selected |
| Yes | N/A | N/A | Input | PU | Safe Mode | PU | Yes ⁽²⁾ | N/A | SAFE MODE ⁽³⁾ |
| Yes | N/A | N/A | Input | PD | Safe Mode | PD | Yes | N/A | SAFE MODE |
| Yes | N/A | N/A | Output | 1 | Safe Mode | PD | Yes | N/A | SAFE MODE |
| Yes | N/A | N/A | Output | 0 | Safe Mode | PD | Yes | N/A | SAFE MODE |
| Yes | N/A | N/A | - | Hi-Z | Safe Mode | PD | Yes | N/A | SAFE MODE |
| No | Yes | N/A | Input | PU | Input | PU | Yes | Yes ⁽⁴⁾ | GPIO_XX ⁽⁵⁾ |
| No | Yes | N/A | Input | PD | Input | PD | Yes | Yes | GPIO_XX |
| No | Yes | N/A | Output | 1 | Input | PD | Yes | Yes | GPIO_XX |
| No | Yes | N/A | Output | 0 | Input | PD | Yes | Yes | GPIO_XX |
| No | Yes | N/A | - | Hi-Z | Input | PD | Yes | Yes | GPIO_XX |
| No | No | Yes | Input | PU | Input | PU | Yes | N/A ⁽⁴⁾ | N/A (default) |
| No | No | Yes | Input | PD | Input | PD | Yes | N/A | N/A (default) |
| No | No | Yes | Output | 1 | Output | 1 | Yes | N/A | N/A (default) ⁽⁶⁾ |
| No | No | Yes | Output | 0 | Output | 0 | Yes | N/A | N/A (default) ⁽⁶⁾ |
| No | No | Yes | - | Hi-Z | Input | PD | Yes | N/A | N/A (default) |
| No | No | No | Input | PU | Input | PU | Yes | N/A ⁽⁴⁾ | N/A (default) |
| No | No | No | Input | PD | Input | PD | Yes | N/A | N/A (default) |
| No | No | No | Output | 1 | Output | 1 | Yes | N/A | N/A (default) |
| No | No | No | Output | 0 | Output | 0 | Yes | N/A | N/A (default) |
| No | No | No | - | Hi-Z | Input | PD | Yes | N/A | N/A (default) |

⁽¹⁾ PU = Pullup; PD = Pulldown; Hi-Z = High impedance

⁽²⁾ If a certain device pad is left unconnected, its associated padconfiguration register INPUTENABLE bit must be explicitly disabled in software (set to 0b0), regardless of pad MUXMODE bit field value.

⁽³⁾ If a certain pad has a defined safe_mode and is left unconnected in an application, it is recommended to keep its padconfiguration MuxMode value at 0x7 (that is, safe_mode).

⁽⁴⁾ There is no software control over the pad associated output buffer in the Control Module. In case of a GPIO function selection, the output buffer is hardware enabled once the user enables corresponding pin output direction in the GPIOx.GPIO_OE control register.

⁽⁵⁾ If a certain pad does not have a safe_mode but has an associated GPIO function, it is recommended to set its padconfiguration register MuxMode to select the GPIO mode.

⁽⁶⁾ If one of the other mux modes available is bidirectional or input-only, then the nondefault mux mode could be used and configured with input disabled.

18.4.9 Extended-Drain I/O and PBIAS Cell

The device mainly supports 1.8-V I/O voltage on its interfaces, with the exception of MMC/SD/SDIO1 interface, which supports both 1.8-V and 3.0-V voltages. The need for embedded extended-drain I/Os on MMC/SD/SDIO1 interface imposes the use of embedded PBIAS cell MMC1_PBIAS to provide a 1.8-V or 3.0-V reference.

A second PBIAS cell (PBIAS1) is integrated in the device. One of its associated extended-drain I/O cells operates signals of the gpio_wk0 through gpio_wk2 I/Os.

A separate extended-drain I/O cell (USBC1_ICUSB extended-drain I/O cell) is shared between usbc1_icusb_dp, usbc1_icusb_dm (MUXMODE = 0x0), and gpio_98 and gpio_99 (MUXMODE = 0x3) pads. The USBC1_ICUSB I/O cell and extended-drain I/O cells gpio_wk0 through gpio_wk2 are biased by the same PBIAS1 output voltage.

NOTE: With the appropriate PBIAS cell configuration, the different I/Os muxed on the sdmmc1, usbc1_icusb, and gpio_wk0 through gpio_wk2 pads can operate at 1.8-V or 3.0-V-power supply.

The MMC1_PBIAS cell and its associated MMC1 extended-drain I/O is software-controlled by bits in the [CONTROL_PBIASLITE](#) and [CONTROL_MMC1](#) registers of the device core control module. For descriptions of these registers, see [Table 18-576](#) and [CONTROL_MMC1](#) in [Section 18.6.6](#), [SYSCTRL_PADCONF_CORE Register](#). PBIAS1 and associated GPIO_WKx and USBC1_ICUSB_x I/Os are software-controlled by bits in the [CONTROL_PBIASLITE](#), [CONTROL_MMC1](#), and [CONTROL_GPIOWK](#) registers. For descriptions of these registers, see [Table 18-576](#), [CONTROL_MMC1](#) in [Section 18.6.6](#), [SYSCTRL_PADCONF_CORE Register Summary](#), and [CONTROL_GPIOWK](#) in [Section 18.6.9](#), [SYSCTRL_PADCONF_WKUP Register Description](#).

[Figure 18-12](#) shows the functional block diagram with the connections between the PBIAS cells and the extended-drain I/O cells.

Figure 18-12. Functional Block Diagram

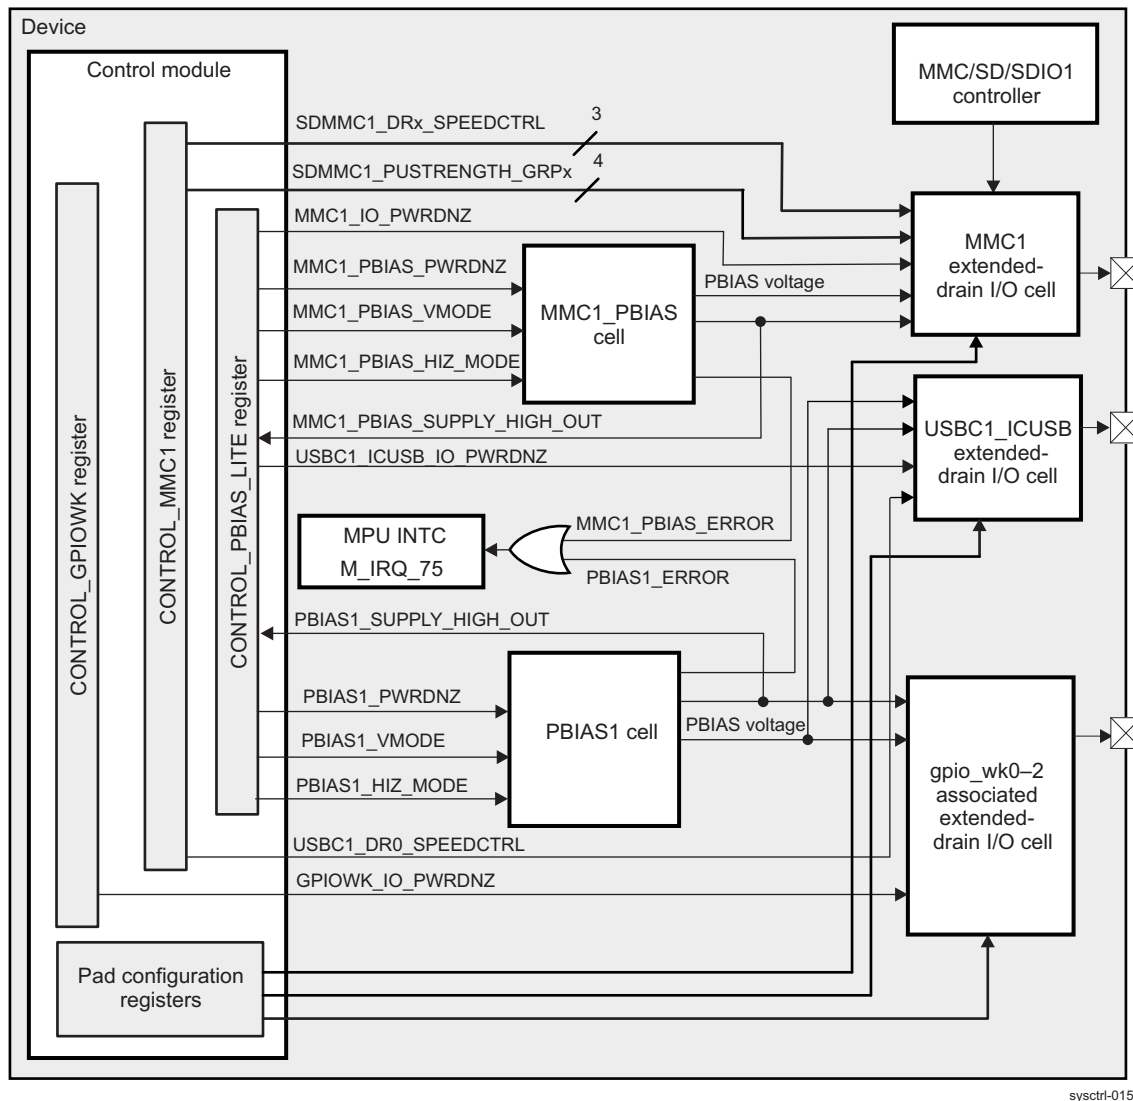

Table 18-12. PBIAS Cell and Extended-Drain I/O Pin CONTROL_PBIAS_LITE Bit Control

| Control Signals for Different PBIAS and Extended-Drain I/O Cells | Description |
|------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MMC1_PBIAS_PWRDNZ | Protects the MMC1_PBIAS cell when the SDMMC1_VDDS supply voltage is not stable. Software must keep this signal to 0b0 whenever this voltage ramps up/down or changes. When this bit is at 0, the PBIAS output voltage is equal to SDMMC1_VDDS voltage and the PBIAS supply detector is disabled. |
| MMC1_PBIAS_VMODE | Sets the SDMMC1_VDDS voltage level (MMC1_PBIAS side) according to which MMC1_PBIAS cell generates appropriate biasing levels for the MMC1 extended-drain I/O. The default state of this bit is high, indicating that the voltage level SDMMC1_VDDS is 3.0 V. |
| MMC1_PBIAS_HIZ_MODE | When MMC1_PBIAS_HIZ_MODE is set to 1 the PBIAS output is in high impedance. MMC1_PBIAS_ERROR is automatically set to 1, when MMC1_PBIAS_HIZ_MODE = 1. When MMC1_PBIAS_HIZ_MODE = 0, MMC1_PBIAS cell is in normal operation mode. |
| MMC1_PBIAS_SUPPLY_HIGH_OUT | Output from the internal MMC1_PBIAS voltage supply detector, which describes whether the SDMMC1_VDDS supply is 3.0 V or 1.8 V. |

Table 18-12. PBIAS Cell and Extended-Drain I/O Pin CONTROL_PBIAS_LITE Bit Control (continued)

| Control Signals for Different PBIAS and Extended-Drain I/O Cells | Description |
|------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MMC1_PBIAS_ERROR | Indicates whether the software-programmed MMC1_PBIAS_VMODE level matches the MMC1_PBIAS_SUPPLY_HI_OUT output signal during normal operation. |
| MMC1_IO_PWRDNZ | Protects the MMC1 I/O extended-drain cell when the SDMMC1_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SDMMC1_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating. |
| SDMMC1_DRx_SPEEDCTRL, x = (0..2) | Speed control signals for three different SDMMC1 pad groups identified within the MMC1 I/O cell |
| SDMMC1_PUSTRENGTH_GRPx, x = (0..3) | Pullup strength controls for four different SDMMC1 pad groups identified within the MMC1 I/O cell |
| PBIAS1_PWRDNZ | Protects the PBIAS1 cell when the SIM_VDDS supply voltage is not stable. Software must keep PWRDNZ signal to 0b0 whenever this supply voltage is ramps up/down or changes. When this bit is at 0, the PBIAS1 output voltage is equal to SIM_VDDS voltage and the PBIAS supply detector is disabled. |
| PBIAS1_VMODE | Sets the SIM_VDDS voltage level (PBIAS1 side) according to which PBIAS1 cell generates appropriate biasing levels for the GPIOWK0GPIOWK2 and USBC1_ICUSB associated extended-drain I/Os. The default state of this bit is high, indicating that the voltage level SIM_VDDS is 3.0 V. |
| PBIAS1_HIZ_MODE | When PBIAS1_HIZ_MODE is set to 1 the PBIAS1 output is in HIGH impedance. PBIAS1_ERROR is automatically set to 1, when PBIAS1_HIZ_MODE = 1. When PBIAS1_HIZ_MODE = 0, PBIAS1 is in normal operation mode. |
| PBIAS1_SUPPLY_HIGH_OUT | Output from the internal PBIAS1 voltage supply detector, which describes whether the SIM_VDDS supply is 3.0 V or 1.8 V. |
| PBIAS1_ERROR | Indicates whether the software-programmed PBIAS1_VMODE level matches the PBIAS1_SUPPLY_HI_OUT output signal during normal operation. |
| GPIOWK_IO_PWRDNZ | Protects the GPIOWK0GPIOWK2 associated extended-drain I/O cell when the SIM_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating. |
| PAD_GPIO_WK1_LOW | This signal should be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk1 pad. This is to ensure normal use of the gpio_wk1 pad. |
| 0.22 PAD_GPIO_WK2_LOW | This signal should be set to 0b0 to disable the strong pulldown available after reset on the gpio_wk2 pad. This is to ensure normal use of the gpio_wk2 pad. |
| 0.23 USBC1_ICUSB_IO_PWRDNZ | Protects the USBC1_ICUSB extended-drain I/O cell when the SIM_VDDS voltage is not stable. Software must keep this signal to 0b0 whenever the SIM_VDDS supply voltage ramps up/down or changes. When this bit is at 0, the pad is floating. |
| 0.24 USBC1_DR0_SPEEDCTRL | Speed controls for the ICUSB pads associated with the USBC1_ICUSB associated I/O cell |

NOTE: When HIZ_MODE = 1, the PBIAS output (the pbias_mmc1 pin) must be tied to a defined external potential to avoid stress on transistors.

Table 18-13 lists the power supplies for PBIAS and the extended-drain I/O cells.

Table 18-13. Power Supplies

| Name | Description |
|-------------|--------------------------------------------------------------------|
| VDD2 | Core voltage supply |
| SDMMC1_VDDS | MMC1 I/O cell supply voltage nominal 1.8 V/3.0 V |
| SIM_VDDS | USBC1_ICUSB and GPIOWK I/O cell supply voltage nominal 1.8 V/3.0 V |
| VDDS | 1.8-V supply for the input buffer |

18.4.9.1 PBIAS Cell

The MMC1_PBIAS cell provides a bias for the MMC/SD/SDIO1 extended-drain I/O cell used with high voltage for the MMC/SD/SDIO1 interface. This PBIAS cell provides a voltage reference (PBIAS voltage) for biasing extended-drain in the MMC/SD/SDIO1 cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SDMMC1_VDDS) value (1.8 V or 3.0 V) and update, with its status, the [CONTROL_PBIASLITE](#)[24] MMC1_PBIASLITE_SUPPLY_HI_OUT bit. However, this is possible when voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the MMC1_PBIAS_PWRDNZ signal is set to 0b1).

The PBIAS1 cell provides a reference voltage for biasing the gpiowk0gpiowk2 associated extended-drain I/O cell and the USBC1_ICUSB extended-drain I/O cell. In addition to generating the bias voltage, the cell can detect the supply voltage (SIM_VDDS) value (1.8 V or 3.0 V) and update, with its status, the [CONTROL_PBIASLITE](#)[30] PBIASLITE1_SUPPLY_HI_OUT bit. However, this is possible when voltage reaches its steady state (the internal PBIAS voltage detector is enabled only when the PBIAS1_PWRDNZ signal is set to 0b1).

CAUTION

A PBIAS cell lets the peripheral associated with its corresponding extended-drain I/O cells support 1.8-V and 3.0-V voltages. A PBIAS cell is not a part of a peripheral, but a part of the device I/Os to which this peripheral is internally connected. These device I/Os are not exclusive to one peripheral; through I/O multiplexing they can be connected to other internal signals. It is necessary to configure the PBIAS to enable the I/Os, regardless of how I/O multiplexing is configured for these device I/Os. In other words, independently of which signal is internally connected to a device I/O powered by SDMMC1_VDDS or SIM_VDDS, the corresponding PBIAS must be configured.

18.4.9.2 Extended-Drain I/O

The following MMC/SD/SDIO1 interface signals (selected when MuxMode = 0) use the device I/Os associated with the MMC1 extended-drain I/O cell:

- sdmmc1_clk
- sdmmc1_cmd
- sdmmc1_dati (where i = 0 to 7)

The MMC1 I/O cell is powered externally through the vdds_sdmmc1 pad.

NOTE: The MMC1 I/O cell associated device I/Os are also shared with other signals. gpio100gpio109, etc. are available when MuxMode is different than 0x0. If signals other than sdmmc1_x are selected, the MMC1 I/O cell must also be configured.

NOTE: For multiplexed gpio signals on the MMC1 I/O cell (gpio_100 through gpio_109), to function appropriately in standard 1.8-V mode, the [CONTROL_PBIASLITE](#)[21] MMC1_PBIASLITE_VMODE through [CONTROL_PBIASLITE](#)[26] MMC1_PWRDNZ bits must be set to 0b0. When these bits are set, and the externally-applied I/O cell power supply voltage (1.8 V) is stabilized, gpio signals can be enabled on the pads by setting the [CONTROL_PBIASLITE](#)[22] MMC1_PBIASLITE_PWRDNZ bit to 0b1 (power-up MMC1_PBIAS cell) and the [CONTROL_PBIASLITE](#)[26] MMC1_PWRDNZ bit to 0b1 (power-up MMC1 extended-drain I/O cell).

For more information about signal multiplexing, see [Table 18-9](#).

For GP device I/Os, which are part of the GPIOWK pads associated extended-drain cell, Muxmode = 3 and Muxmode = 6 are functional.

With Muxmode set to 0x3, the following signals are present:

- gpio_wk0

- gpio_wk1
- gpio_wk2

With Muxmode set to 0x6, the output signals hw_dbg1, hw_dbg2, and hw_dbg3 are present at the gpio_wk0, gpio_wk1, and gpio_wk2 pads, respectively.

This PBIAS1 associated extended-drain I/O cell is externally powered through the vdds_sim pad.

NOTE: The GPIOWK-associated I/O cell must be properly configured when the gpiowk0gpiowk2 pads are used. For more information about signal multiplexing, see [Table 18-9](#).

NOTE: For the gpio_wk0 through gpio_wk2 signals to function appropriately in standard 1.8-V mode, the [CONTROL_PBIASLITE\[27\]](#) PBIASLITE1_VMODE through [CONTROL_PBIASLITE\[31\]](#) PBIASLITE1_HIZ_MODE bits and the [CONTROL_GPIOWK\[28\]](#) GPIOWK_IO_PWRDNZ bit must be set to 0b0. When these bits are set, and the externally-applied I/O cell power supply voltage (1.8 V) is stabilized, gpio signals can be enabled on the pads by setting the [CONTROL_PBIASLITE\[28\]](#) PBIASLITE1_PWRDNZ bit to 0b1 (power-up PBIAS1 cell) and the [CONTROL_GPIOWK\[28\]](#) GPIOWK_IO_PWRDNZ bit to 0b1 (power-up extended-drain I/O cell).

The following USBC1_ICUSB interface signals (selected through MuxMode = 0) use the device I/Os associated with the USBC1_ICUSB extended-drain I/O cell:

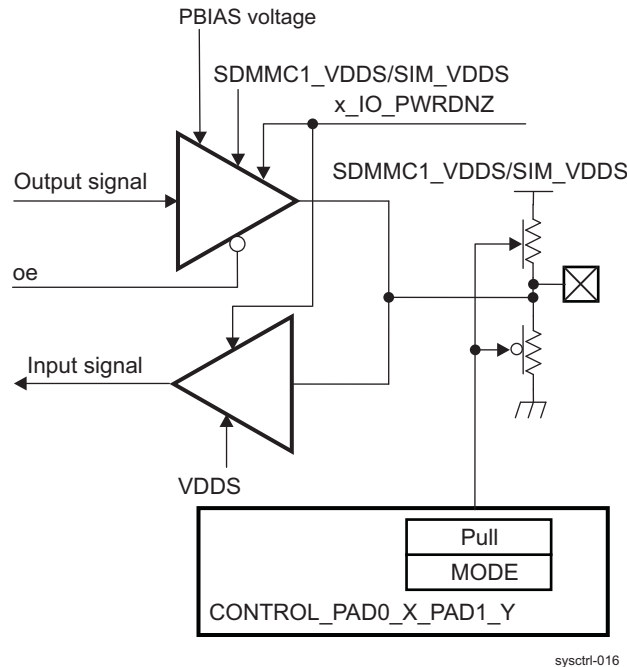

- usbc1_icusb_dp
- usbc1_icusb_dm

The USBC1_ICUSB I/O cell uses the same external power supply voltage as the GPIOWK cell (vdds_sim pad).

NOTE: The USBC1_ICUSB I/O cell associated device I/Os are also shared with the gpio_98 and gpio_99 signals, when MuxMode = 0x3. USBC1_ICUSB cell must be configured to allow for gpio_98 and gpio_99 operation. For more information about signal multiplexing, see [Table 18-9](#).

NOTE: For the gpio_98 through gpio_99 signals to function appropriately in standard 1.8-V mode, the [CONTROL_PBIASLITE\[27\]](#) PBIASLITE1_VMODE through [CONTROL_PBIASLITE\[31\]](#) PBIASLITE1_HIZ_MODE bits and the [CONTROL_PBIASLITE \[20\]](#) USBC1_ICUSB_PWRDNZ bit must be set to 0b0. When these bits are set, and the externally-applied I/O cell power supply voltage (1.8 V) is stabilized, gpio signals can be enabled on the pads by setting the [CONTROL_PBIASLITE\[28\]](#) PBIASLITE1_PWRDNZ bit to 0b1 (power-up PBIAS1 cell) and the [CONTROL_PBIASLITE\[20\]](#) USBC1_ICUSB_PWRDNZ bit to 0b1 (power-up extended-drain I/O cell).

[Figure 18-13](#) describes the extended-drain I/O cells.

Figure 18-13. Extended-Drain I/O

The extended-drain I/O cells have the following I/O signals:

- Output signal, input signal, and oe, which comes from the selected I/O module with the correctly configured MUXMODE field within the corresponding CONTROL_CORE_PAD0_X_PAD1_Y or CONTROL_WKUP_PAD0_X_PAD1_Y register.

NOTE: Extended-drain I/Os are muxed I/Os with mode and pullup/down configurations programmable in the control module.

- The PBIAS voltage is a voltage reference for biasing the extended-drain in the MMC1, USBC1_ICSUB, and GPIOWK I/O cells.
- The PWRDNZ signals are used to protect the I/O cells when the SDMMC1_VDD5/SIM_VDD5 voltage is not stable.

CAUTION

Software must keep the PWRDNZ-related signals to 0b0 whenever the SDMMC1_VDD5 or SIM_VDD5 signal ramps up/down or changes. When it is 0, the pad is floating (the pad may not reflect the state of the output signal, and the input signal may not reflect the state of the pad).

- The [CONTROL_PBIASLITE\[24\]](#) MMC1_PBIASLITE_SUPPLY_HI_OUT bit is a status bit on the SDMMC1_VDD5 value and is used to inform the MMC1 I/O cell about the value of the SDMMC1_VDD5 signal.
- The [CONTROL_PBIASLITE\[30\]](#) PBIASLITE1_SUPPLY_HI_OUT bit is a status bit on the SIM_VDD5 value and is used to inform the gpiowk0gpiowk2 associated I/O cell and USBC1_ICUSB I/O cell about the value of the SIM_VDD5 signal.

For more information about the software configurations of the extended-drain I/Os and PBIAS cells, see [Section 18.5.1.2.2, Extended-Drain I/Os and PBIAS Cells Programming Guide](#).

NOTE: The device can be supplied by an external power IC. TI provides such a global solution to its customers with the TWL60xx power IC.

If the device is associated with the TWL60xx power IC, before using an extended-drain I/O interface, software must program the TWL60xx to enable the VMMC1 (for the MMC/SD/SDIO1 or muxed I/O modules) or VSIM (for the GPIOWK0, GPIOWK2, USBC1_ICUSB, or muxed I/Os) and the LDO to provide a 1.8-V/3.0-V voltage. This is done by software through the inter-integrated circuit (I²C) interface that links the device and the TWL60xx IC.

CAUTION

The power supply voltage generated from the companion power IC and applied on the vdds_sdmmc1 or vdds_sim device pins must be programmed according to the recommendations for the currently selected I/O module power supply range.

If the application does not want the I/O interface to run at 3.0 V, software users must then assert the VMODE signal to low for 1.8-V activity: in this case, the PBIAS is connected to ground.

Table 18-14 lists the control signal with the corresponding control bits from the [CONTROL_PBIASLITE](#), [CONTROL_MMC1](#), and [CONTROL_GPIOWK](#) registers to configure the PBIAS and the extended-drain I/O cells. These signals can be software-controlled.

Table 18-14. PBIAS/Extended-Drain I/O Cells Control Signals

| Control Signals for Different PBIAS and Extended-Drain I/O Cells | Bits Used for PBIAS Cell and I/O Cell Configurations for Different I/O Modules | Reset Value |
|------------------------------------------------------------------|--------------------------------------------------------------------------------|-------------|
| MMC1_PBIAS_PWRDNZ | CONTROL_PBIASLITE [22] MMC1_PBIASLITE_PWRDNZ | 0 |
| MMC1_PBIAS_VMODE | CONTROL_PBIASLITE [21] MMC1_PBIASLITE_VMODE | 1 |
| MMC1_PBIAS_HIZ_MODE | CONTROL_PBIASLITE [25] MMC1_PBIASLITE_HIZ_MODE | 0 |
| MMC1_PBIAS_SUPPLY_HIGH_OUT | CONTROL_PBIASLITE [24] MMC1_PBIASLITE_SUPPLY_HI_OUT | 0 |
| MMC1_PBIAS_ERROR | CONTROL_PBIASLITE [23] MMC1_PBIASLITE_VMODE_ERROR | 0 |
| MMC1_IO_PWRDNZ | CONTROL_PBIASLITE [26] MMC1_PWRDNZ | 0 |
| SDMMC1_DRx_SPEEDCTRL, x = (0...2) | CONTROL_MMC1 [27] SDMMC1_DR0_SPEEDCTRL | 0 |
| | CONTROL_MMC1 [26] SDMMC1_DR1_SPEEDCTRL | 0 |
| | CONTROL_MMC1 [25] SDMMC1_DR2_SPEEDCTRL | 0 |
| SDMMC1_PUSTRENGTH_GRPx, x = (0...3) | CONTROL_MMC1 [31] SDMMC1_PUSTRENGTH_GRP0 | 1 |
| | CONTROL_MMC1 [30] SDMMC1_PUSTRENGTH_GRP1 | 0 |
| | CONTROL_MMC1 [29] SDMMC1_PUSTRENGTH_GRP2 | 1 |
| | CONTROL_MMC1 [28] SDMMC1_PUSTRENGTH_GRP3 | 1 |
| PBIAS1_PWRDNZ | CONTROL_PBIASLITE [28] PBIASLITE1_PWRDNZ | 0 |
| PBIAS1_VMODE | CONTROL_PBIASLITE [27] PBIASLITE1_VMODE | 1 |
| PBIAS1_HIZ_MODE | CONTROL_PBIASLITE [31] PBIASLITE1_HIZ_MODE | 0 |
| PBIAS1_SUPPLY_HIGH_OUT | CONTROL_PBIASLITE [30] PBIASLITE1_SUPPLY_HI_OUT | 0 |
| PBIAS1_ERROR | CONTROL_PBIASLITE [29] PBIASLITE1_VMODE_ERROR | 0 |
| GPIOWK_IO_PWRDNZ | CONTROL_GPIOWK [28] GPIOWK_IO_PWRDNZ | 0 |
| PAD_GPIO_WK1_LOW | CONTROL_GPIOWK [31] PAD_GPIO_WK1_LOW | 1 |
| PAD_GPIO_WK2_LOW | CONTROL_GPIOWK [29] PAD_GPIO_WK2_LOW | 1 |
| USBC1_ICUSB_IO_PWRDNZ | CONTROL_PBIASLITE [20] USBC1_ICUSB_PWRDNZ | 0 |
| USBC1_DR0_SPEEDCTRL | CONTROL_MMC1 [24] USBC1_DR0_SPEEDCTRL | 0 |

The two PBIAS cells support two ranges of I/O: SDMMC1_VDDS/SIM_VDDS: 1.8 V, typical for low-voltage applications, and 3.0 V, typical for high-voltage applications. For each supply voltage range, the cell generates suitable bias voltage (PBIAS) for extended-drain PMOS devices.

CAUTION

The PBIAS cell must be programmed according to peripheral power supply voltage. See [Table 18-15](#).

Table 18-15. Voltage Configuration⁽¹⁾

| PBIASLITEVMODE Configuration | SDMMC1_VDDS/SIM_VDDS Voltage | Type of Operation |
|------------------------------|------------------------------|---------------------------------------|
| 1.8 V | 1.8 V | Normal 1.8-V operation |
| 1.8 V | 3.0 V | Damaging configuration ⁽²⁾ |
| 3.0 V | 1.8 V | Degraded functionality ⁽²⁾ |
| 3.0 V | 3.0 V | Normal 3.0-V operation |

⁽¹⁾ For damaging configuration, hardware system protection is provided to prevent deterioration of the associated extended-drain I/Os.

⁽²⁾ These modes must not be used.

The PBIAS output voltage is the same as SDMMC1_VDDS/SIM_VDDS voltage when the corresponding PWRDNZ bit is low. Once the SDMMC1_VDDS / SIM_VDDS supply is stable, software can release the PWRNDZ (setting it high). This starts up the PBIAS cell work to generate the PBIAS voltage. During the completion process the corresponding I/Os cannot be used for transmitting data. If VMODE is set correctly (compared with supply detector output and found to be the same), then PBIAS output voltage is generated based on the value of VMODE.

NOTE: In the case of a damaging configuration, hardware system protection prevents deterioration of the associated extended-drain I/Os.

CAUTION

The following requirements are critical for an extended-drain I/O cell:

- The VMODE bit must be defined before the PWRNDZ bit is made high (cell is brought out of power-down mode).
- The default state of the VMODE bit is high (indicates 3.0-V operation).
- The PWRNDZ bit must be kept low whenever the SDMMC1_VDDS/SIM_VDDS supply ramps up/down or changes. This can be damaging.
- Supply detector is disabled when PWRDNZ = 0 and in this case, supply detector output (SUPPLY_HI_OUT) is initialized to 0.

18.4.9.3 PBIAS Error Generation

If VMODE and supply detector outputs are unequal. It takes 4 μ s for the comparator to process the inputs and generate VMODE_ERROR flag.

[Table 18-16](#) summarizes the generation of the PBIAS error signals, MMC1_PBIAS_ERROR of the MMC1_PBIAS cell and PBIAS1_ERROR of the PBIAS1 cell. They depend on the various [CONTROL_PBIASLITE](#) bit combinations. The shaded row is a potential condition that could cause a reliability issue if not detected. To prevent this reliability issue, the PBIAS voltage is tied to SDMMC1_VDDS/SIM_VDDS when the PBIAS error signal is high. This disables the I/Os.

CAUTION

Although asserting VMODE_ERROR to 1 provides that PBIAS voltage is equal to SDMMC1_VDDS/SIM_VDDS, this does not completely protect the I/O cells. It is also recommended that all the I/Os are powered down, setting the PWRDNZ mode bits of the corresponding I/O cells to 0b0 by software as soon as VMODE_ERROR = 0b1.

Table 18-16. PBIAS Error Signal Truth Table

| VMODE | PWRDNZ | HIZ_MODE | SUPPLY_HI_OUT | VMODE_ERROR |
|-------|--------|----------|---------------|-------------|
| 0 | 0 | X | 0 | 0 |
| 0 | 1 | 0 | 0 | 0 |
| 0 | 1 | 0 | 1 | 1 |
| X | 1 | 1 | X | 1 |
| 1 | 0 | X | 0 | 0 |
| 1 | 1 | 0 | 0 | 1 |
| 1 | 1 | 0 | 1 | 0 |

NOTE: VMODE_ERROR =0b1: VMODE level is not the same as SUPPLY_HI_OUT or Hi-Z mode is selected.

VMODE_ERROR = 0b0: VMODE level is the same as SUPPLY_HI_OUT or VMODE is not considered (PWRDNZ = 0b0).

The MMC1_PBIAS_ERROR and PBIAS1_ERROR signals are ORed and the outputs are mapped to the microprocessor unit (MPU) subsystem interrupt controller (INTC). The interrupt line MA_IRQ_75 is activated upon error occurrence. For more information about the Cortex™-A9 MPU INTC registers and their description, see the *ARM Cortex-A9 MPCore Technical Reference Manual* (available at infocenter.arm.com/help/index.jsp).

The CONTROL_PBIASLITE[29] PBIASLITE1_VMODE_ERROR bit and CONTROL_PBIASLITE[23] MMC1_PBIASLITE_VMODE_ERROR bits also indicate whether this kind of error occurs.

18.4.9.4 Critical Timing Requirements

It is crucial that the PBIAS and I/O cell-related PWRDNZ bits are deasserted (made 1 from 0) only after the SDMMC1_VDDS/SIM_VDDS power supply voltage is stable in the device. The cells support only the case when 1.8-V input buffer supply voltage VDDS ramps up before VDD2 (core voltage). This power-up sequence is automatically provided upon power-on reset by hardware in the device. Take care to ensure that the externally provided SDMMC1_VDDS/SIM_VDDS voltage (1.8 V/ 3 V) is powered up, only after VDD2 and VDDS reach their steady state.

Figure 18-14 shows the only possible power-up sequence and the expected behavior of the PWRNDZ mode-related bits with regard to supplying voltage ramp up.

Figure 18-14. VDDS Ramps Up Before VDD2

18.4.10 Band Gap Voltage and Temperature Sensor

The device supplies a voltage reference and a temperature sensor feature that are gathered in the band gap voltage and temperature sensor (VBGAPTS) module. The band gap provides current and voltage reference for its internal circuits and other analog IP blocks. The analog-to-digital converter (ADC) produces an output value that is proportional to the silicon temperature.

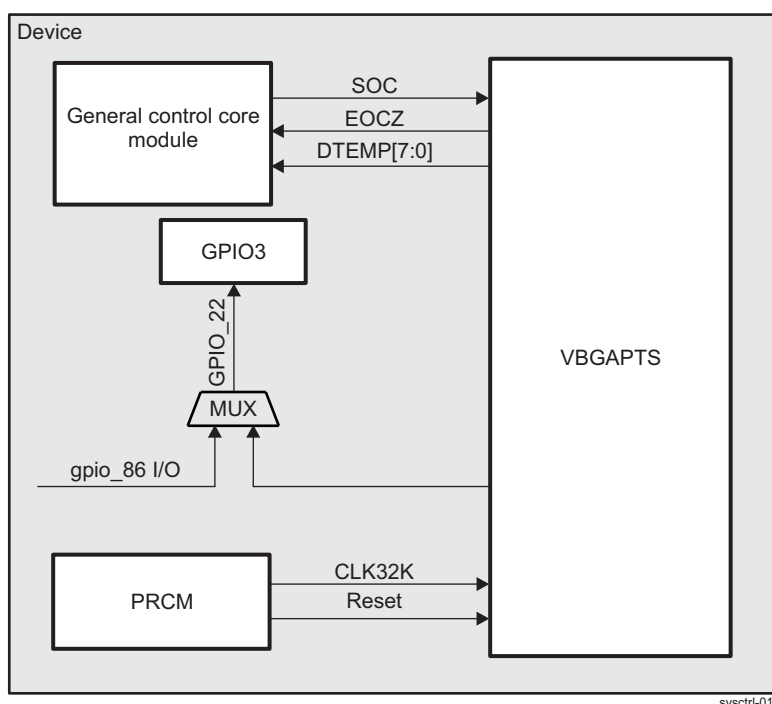

The main features of the BGAPTS module are:

- A constant voltage reference output: 0.5 V
- Five constant current reference outputs of 1 μ A
- Analog supply is a nominal 1.8 V.
- Small ADC with 8-bit digital output
- Off mode compatible
- Thermal shutdown comparator output

The band gap and the temperature sensor are software-controlled by bits in the `CONTROL_TEMP_SENSOR` register within the `SYSCTRL_GENERAL_CORE` module instance. For the description of this register, see [Table 18-188](#).

[Figure 18-15](#) is the functional block diagram of the band gap and the temperature sensor module.

Figure 18-15. Functional Block Diagram

[Table 18-17](#) describes the input and output signals for the BGAPTS module.

Table 18-17. Band Gap Voltage and Temperature Sensor Signal Description

| Pin | I/O ⁽¹⁾ | Description |
|------------|--------------------|-------------------------------------------------------------------------------------------------|
| SOC | I | Start of Conversion signal. A transition to high starts a new ADC conversion cycle. |
| EOCZ | O | End of Conversion signal. When low, the signal indicates that the value of DTEMP[7:0] is valid. |
| DTEMP[7:0] | O | Temperature data from the temperature sensor. This value is valid when EOCZ is low. |

⁽¹⁾ I=Input, O=Output

Table 18-17. Band Gap Voltage and Temperature Sensor Signal Description (continued)

| Pin | I/O ⁽¹⁾ | Description |
|----------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| CONTCONV | I | Configures the temperature sensor in continuous conversion mode. 0: ADC single conversion mode 1: ADC continuous conversion mode |
| TSHUT | O | Thermal shutdown comparator output. The signal is high during normal operation and goes low during a thermal shutdown event. |
| CLRZ | I | When low the temperature sensor is in reset mode. This signal must be low when OFFMODE is high. |
| CLK32K | I | 32-kHz functional clock from the CORE power domain used by the temperature sensor during temperature conversion |

All the configuration signals are available through the [CONTROL_TEMP_SENSOR](#) register.

NOTE: VBGAPTS CLK32K is used only for the temperature sensor. When ADC is not converting, this clock can be switched off (CLK32K = 0). In this case, DTEMP[7:0] retains the temperature code obtained at the previous conversion.

18.4.10.1 Band Gap Voltage Reference

The band gap voltage reference feature provides several constant voltage and current references for its internal circuits, but also for other analog modules.

The voltage reference signal is a 0.5-V output. This output is used internally by the module and is exported for external modules or for tests.

The current reference signals consist in five lines, each of which generates a 1- μ A current with a 1.8-V voltage. These lines can be used to bias other modules.

18.4.10.2 Temperature Sensor

The temperature sensor feature is used to convert the temperature of the device into a decimal value coded on 8 bits. An internal ADC is used for conversion. This signal is connected internally to a GPIO pin. For more information, see [Chapter 25, General-Purpose Interface](#).

The temperature sensor offers two operating modes: a single conversion mode and a continuous conversion mode.

For more information on thermal sensor characteristics, see the *Junction Temperature Sensor* section in the device data manual.

18.4.10.2.1 Single Conversion Mode (CONTCONV = 0)

When the ADC is idle ([CONTROL_TEMP_SENSOR](#)[8] BGAP_TEMP_SENSOR_EOCZ = 0) and the [CONTROL_TEMP_SENSOR](#)[10] BGAP_TEMP_SENSOR_CONTCONV bit is set to 0, it is possible to ask for a single temperature conversion. To initiate a new conversion, the start of conversion (SOC) signal must be asserted and maintained high until the end of conversion (EOCZ) signal goes high, after which the SOC must be made low by setting the [CONTROL_TEMP_SENSOR](#)[9] BGAP_TEMP_SENSOR_SOC bit to 0. Conversion completion is indicated by a negative edge on EOCZ (the [CONTROL_TEMP_SENSOR](#)[8] BGAP_TEMP_SENSOR_EOCZ bit).

[Figure 18-16](#) shows the timing sequence for a single temperature conversion.

Figure 18-16. Single Conversion Mode (CONTCONV = 0)

sysctrl-019

18.4.10.2.2 Continuous Conversion Mode (CONTCONV = 1)

When the ADC is idle (`CONTROL_TEMP_SENSOR[8] BGAP_TEMP_SENSOR_EOCZ = 0`) and the `CONTROL_TEMP_SENSOR[10] BGAP_TEMP_SENSOR_CONTCONV` bit is set to 1, it is possible to ask for a continuous temperature conversion. To initiate a new conversion, the SOC signal must be asserted and maintained high until the EOCZ signal goes high, after which the SOC must be made low by setting the `CONTROL_TEMP_SENSOR[9] BGAP_TEMP_SENSOR_SOC` bit to 0. The ADC starts converting continuously, and when a conversion is complete, data is written to the `CONTROL_TEMP_SENSOR[7:0] BGAP_TEMP_SENSOR_DTEMP` bit field and EOCZ goes low after four clock cycles.

Section 18.4.11.1 shows the timing sequence for a continuous temperature conversion.

Figure 18-17. Continuous Conversion Mode (CONTCONV = 1)

sysctrl-020

18.4.10.2.3 ADC Codes Versus Temperature

Table 18-18 gives the temperature range corresponding to each value of the `CONTROL_TEMP_SENSOR[7:0] BGAP_TEMP_SENSOR_DTEMP` bit field.

Table 18-18. ADC Code Versus Temperature

| ADC Code | Temperature °C | | ADC Code | Temperature °C | | ADC Code | Temperature °C | | ADC Code | Temperature °C | |
|----------|----------------|-----|----------|----------------|------|----------|----------------|------|----------|----------------|-------|
| | From | To | | From | To | | From | To | | From | To |
| 0 | -40 | -40 | 32 | -5 | -3.5 | 64 | 50 | 52 | 96 | 105 | 107 |
| 1 | -40 | -40 | 33 | -3.5 | -1.5 | 65 | 52 | 53.5 | 97 | 107 | 109 |

18.4.11 Hardware Observability

18.4.11.1 Device Internal Signals Observability Overview

The general control module provides observability features covering different module internal signals related to:

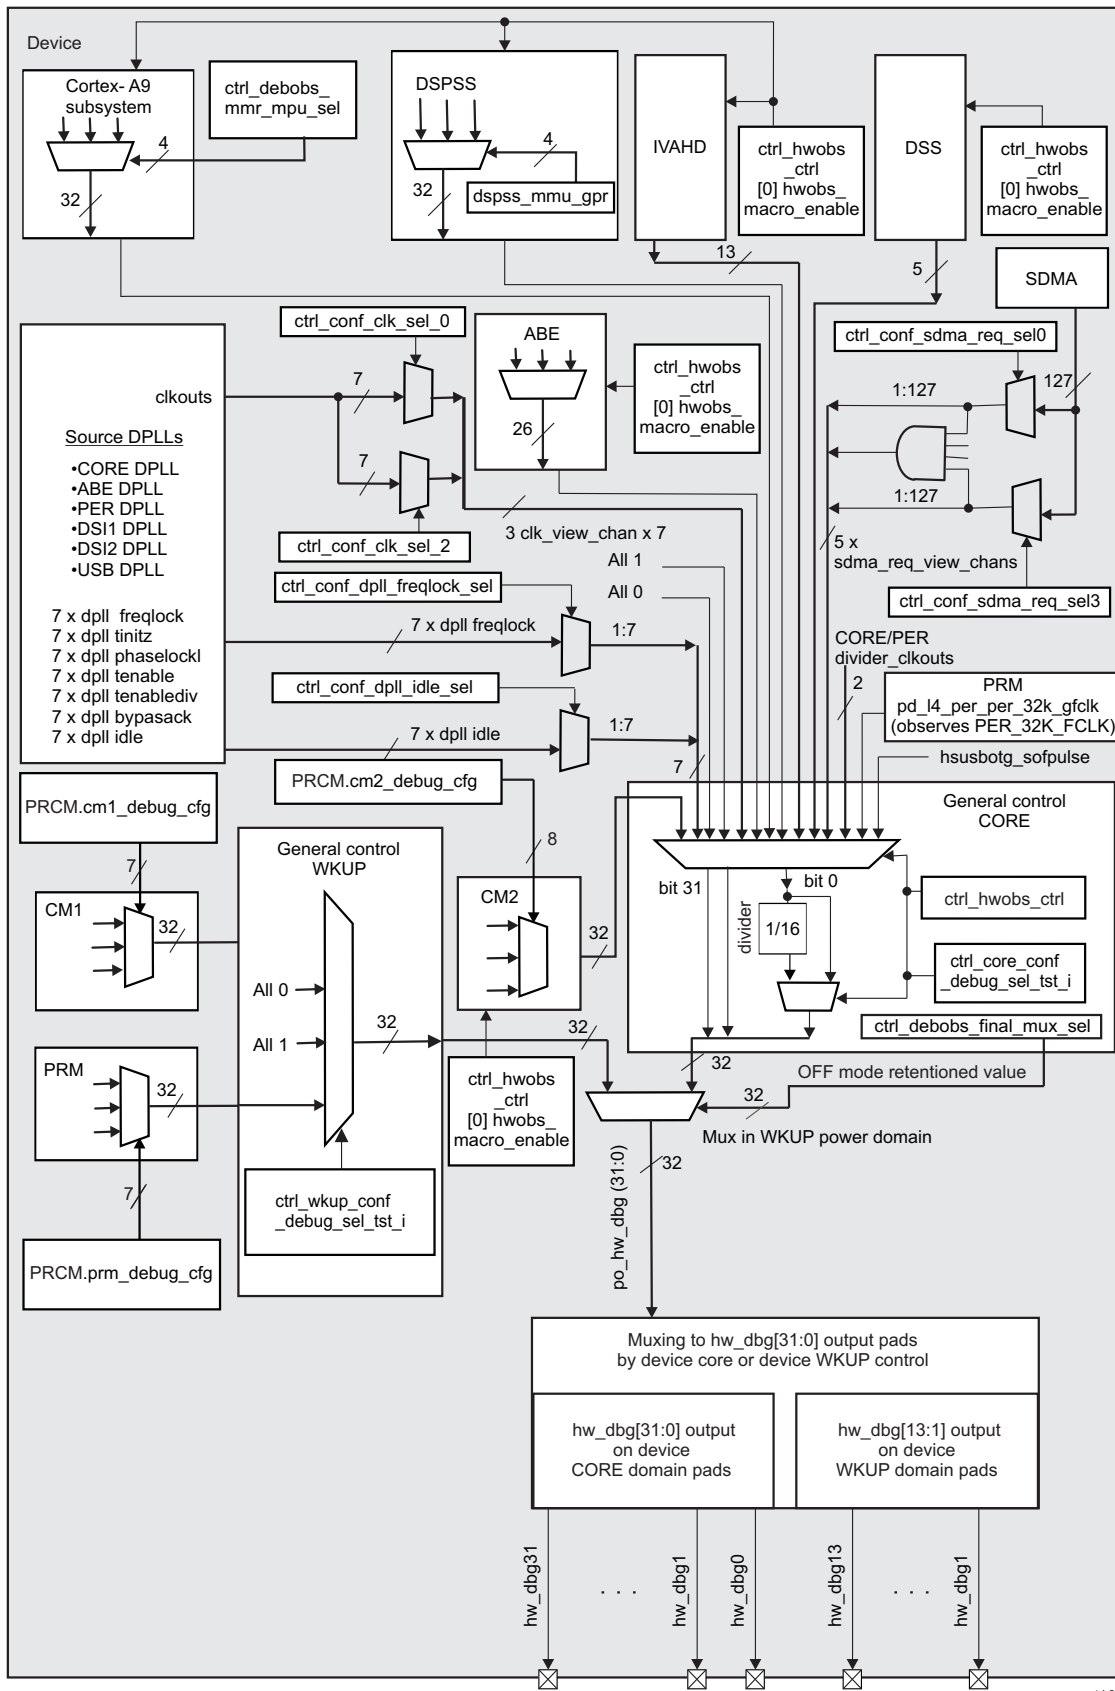

- Power and reset management protocol inside different power domains
- Power domain states/transition indication
- IRQs by different modules
- DMA requests by different modules
- Clocks and clock management

The associated signal multiplexing function is controlled through the hardware observability I/O multiplexing registers (32-bit read/write registers). The selected observable signals are multiplexed between the general control module CORE and/or WKUP power domain and are output on the po_hw_dbg[31:0] observability bus at the boundaries of the general wake-up control module. The po_hw_dbg[31:0] observability outputs are then exported to the device control module logic to be further multiplexed as their corresponding hw_dbg[31:0] signals on the different pads of the WKUP or CORE power domain of the device control module (see [Section 18.4.11.4, Observability Signals Multiplexing at Device Control Module Level](#)).

NOTE: Each signal `po_hw_dbg_i` (where $i = 0$ to 31) of the general control wakeup `po_hw_dbg[31:0]` bus is propagated by device control module-level logic as its corresponding `hw_dbg_i` (where $i = 0$ to 31) signal on the CORE or WKUP power domain pads described in [Section 18.4.11.4, Observability Signals Multiplexing at Device Control Module Level](#).

[Figure 18-18](#) shows an overview of observability multiplexing, which minimizes the number of signals exchanged at the device boundary.

Figure 18-18. Overview of the Hardware Observability Functionality

sysctrl-006

18.4.11.2 Observability Gating Capabilities

The programmer can gate all 32 signals of the observability bus at the observability paths of the CORE and WKUP power domains simultaneously, keeping them either tied to 1, programming [CONTROL_HWOBS_CONTROL](#) [1] HWOBS_ALL_ONE_MODE = 0b1, or keeping them tied to 0, programming [CONTROL_HWOBS_CONTROL](#) [2] HWOBS_ALL_ZERO_MODE = 0b1. This can be useful to check the path from hardware observability to external pads. These two bits must be set to 0 to enable the observability feature for all observability pads.

Additionally, the [CONTROL_HWOBS_CONTROL](#) [0] HWOBS_MACRO_ENABLE bit provides the gating feature only to observability signals muxed in the CORE power domain that come from the following modules (identified in the so-called MACRO group):

- CORTEX-A9 MPU subsystem
- DSP subsystem
- IVA-HD
- Display subsystem
- CM2
- ABE

When [CONTROL_HWOBS_CONTROL](#) [0] HWOBS_MACRO_ENABLE = 0b0, the observability outputs associated with the MACRO group are gated and forced to 0b0.

NOTE: Do not set the observability gating bits ([CONTROL_HWOBS_CONTROL](#) [1] HWOBS_ALL_ONE_MODE and [CONTROL_HWOBS_CONTROL](#) [2] HWOBS_ALL_ZERO_MODE) simultaneously to 1 to avoid undefined states of the observability bus.

The clock frequency of the hw_dbg0 signal can be optionally divided by 1, 2, 4, 8, or 16 by programming the [CONTROL_HWOBS_CONTROL](#) [7:3] HWOBS_CLKDIV_SEL bit field.

NOTE: Only CORE power domain signal hw_dbg0 passes through the [CONTROL_HWOBS_CONTROL](#) programmable divider. This divider is not available to the po_hw_dbg(0) line in the WKUP power domain.

NOTE: To enable observability over the po_hw_dbg(0) bus line, the [CONTROL_HWOBS_CONTROL](#) [7:3] HWOBS_CLKDIV_SEL bit field must be set different than 0. The default value (0) is not enough to see the observability value at the hw_dbg0 pin.

NOTE: The hw_dbg0 frequency division and capability to gate the MACRO group observability signals (hw_dbg i, configurable in the [CONTROL_HWOBS_CONTROL](#) register) are limited to the hardware observability signals hw_dbg i (where i = 0 to 31) multiplexed and propagated in the CORE power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL](#) [i] SELECT = 0b1).

These options do not apply to the hardware observability signals, hw_dbg i (where i = 0 to 31), which are muxed in the WKUP power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL](#) [i] SELECT = 0x0).

18.4.11.3 Observability Signals Multiplexing at General Core/Wake-Up Control Level

Most of the observability multiplexers (MACRO group-modules/DPLLs/sDMA associated) are configurable in the general core control module, which is part of the switchable CORE power domain. There are also signal multiplexers instantiated inside the general wake-up control module (CM1/PRM dedicated), which is part of the WKUP power domain. The 32-bit [CONTROL_DEBOBS_FINAL_MUX_SEL\[31:0\]](#) SELECT bit field, instantiated inside the CORE power domain, selects a signal to be observed between the outputs at CORE and the WKUP multiplexing level. A bit from this register set to 1 selects to route a signal from the CORE power domain to a certain `po_hw_dbgn` ($n = 0 \dots 31$) line, and when set to 0 selects to route a signal from the WKUP power domain to the same line. The output of this top-level multiplexing is further passed to padconfiguration muxing I/O level inside boundaries of the device control module.

NOTE: Although the [CONTROL_DEBOBS_FINAL_MUX_SEL](#) observability control register is in the CORE power domain, its value is retentioned before the device goes into off mode. Thus, the preserved value is used to control the final observability muxer in the WKUP power domain, even when the PD_CORE supply in the device is switched off. Because the `hw_dbgi` signals, which are propagated in the CORE power domain, are not available in off mode, the value of [CONTROL_DEBOBS_FINAL_MUX_SEL\[i\]](#) SELECT = 0b1 (where $i = 0$ to 31) in this case means that the `hw_dbgi` signal is not available at output.

The module and view-channel selection/reduction layer in the CORE domain is configured through the 4-bit MODE bit field in the 32 x 32-bit registers [CONTROL_CORE_CONF_DEBUG_SEL_TST_0](#) through [CONTROL_CORE_CONF_DEBUG_SEL_TST_31](#). The following modules can be selected as source of observability signals (MACRO signal sources):

- Cortex-A9 MPU subsystem
- DSP subsystem
- IVA-HD
- Display subsystem
- CM2
- ABE

Part of the [CONTROL_CORE_CONF_DEBUG_SEL_TST](#) registers are responsible for selecting the sDMA view channels, different DPLL-clock view channels, and other signal view channels.

- 3 x DPLL clockout signal view channels
- 7 x DPLL (other than clkout signal) view channels
- 5 x sDMA signal view channels
- 3 x additional clockout view channels monitoring signals `hwobs_coredivider_clkout3`; `hwobs_perdivider_clkout4` and `per32k_gfclk`.

[Table 18-19](#) summarizes the internal signals multiplexing schema for each of the 32 [CONTROL_CORE_CONF_DEBUG_SEL_TST](#) registers.

A third 1:N selection layer is applied over several signals to route one at a time to a certain view channel output:

- The [CONTROL_CONF_CLK_SEL0\[2:0\]](#) MULT through [CONTROL_CONF_CLK_SEL2\[2:0\]](#) MULT bit fields control multiplexing of DPLL CLKOUT signals over three parallel DPLL clockout view channels. The signal source of a certain view channel can be selected to be one of six DPLLs in the device: CORE DPLL, ABE DPLL, PER DPLL, DS11 DPLL, DS12 DPLL, and USB DPLL.
- The register bit fields associated with the seven different DPLL signal view channels are summarized in [Table 18-20](#). Again, the 3-bit MULT bit field in each of the seven different registers makes it possible to choose the source of the DPLL signal to be one of the following device DPLLs: CORE DPLL, ABE DPLL, PER DPLL, DS11 DPLL, DS12 DPLL, and USB DPLL.
- There are four independent sDMA request view channels, each of which has a dedicated register ([CONTROL_CONF_SDMA_REQ_SEL0](#) through [CONTROL_CONF_SDMA_REQ_SEL3](#)) with a 7-bit MULT bit field to select 1 from a possible 127 sDMA request signals for observation purposes. For more information, see [Chapter 16](#), *sDMA Controller*. The fifth channel, `sdma_req_view_all`, is acquired by applying logical AND reduction over the four currently selected sDMA view channel output signals.
- The general core observability logic input, `hwobs_pd_l4_per_per32k_gfclk`, is tied to the PRM output observability signal, `pd_l4_per_per_32k_gfclk`.

The `pd_l4_per_per_32k_gfclk` signal corresponds to the hardware gated in the L4_PER clock domain clock, `PER_32K_FCLK`, which is directly sourced by the `SCRM_32K_FCLK` clock.

For more information, see [Section 3.6.3.1, PRM Clock Source](#), in [Chapter 3, Power, Reset, and Clock Management](#). The `PER_32K_FCLK` and `32K_FCLK` clocks are also multiplexed for observability in the WKUP power domain when the `PRCM.PRM_DEBUG_CFG[6:0]` bit field is set to `0x6c`. These are the observable signals `devfsm_i0.clk` and `gat_per_32k_gfclk_i0.clkGated`, respectively. For more information, see [Table 18-42](#).

- The general core observability logic input, `hwobs_pd_l4_per_per32k_gfclk`, is tied to the PRM output observability signal, `pd_l4_per_per_32k_gfclk`. The `pd_l4_per_per_32k_gfclk` signal corresponds to the hardware gated in the `PER_32K_FCLK` clock in the L4_PER clock domain. The `PER_32K_FCLK` clock is directly sourced by `SCRM (32K_FCLK)` clock. For more information, see [Section 3.6.3.1, PRM Clock Source](#), in [Chapter 3, Power, Reset, and Clock Management](#). The `PER_32K_FCLK` and `32K_FCLK` clock are also multiplexed for observability in the WKUP domain when the `PRCM.PRM_DEBUG_CFG[6:0]` bit field is set to `0x6c`. These are the observable signals `devfsm_i0.clk` and `gat_per_32k_gfclk_i0.clkGated`, respectively. For more information, see [Table 18-42](#).
- The general core observability logic input, `hwobs_coredivider_clkout3`, is tied to the Core DPLL observability output, `CLK_FUNC_1_0_3`, which

is a direct (nongated, nondivided) version of the CORE DPLL clock output, CLKOUTX2_M3. For more information, see , *DPLL_CORE Description*, in [Chapter 3, Power, Reset, and Clock Management](#).

- The general core observability logic input, hwobs_perdivder_clkout4, is tied to the Core DPLL observability output, CLK_FUNC_1_0_4, which is a direct (nongated, nondivided) version of the PER DPLL clock output, CLKOUTX2_M4. For more information, see [Section 3.6.3.4, DPLL_PER Description](#), in [Chapter 3, Power, Reset, and Clock Management](#).

Table 18-20. DPLL Signal Observability Controls

| Feature | Type | Register/Bit Field/Observability Control | Description |
|------------------------------------------------|---------|-------------------------------------------------------------|------------------------------------------------------|
| Different domain dpll freqlock observability | Control | CONTROL_CONF_DPLL_FREQLOCK_SEL [2:0] MULT | Select DPLL freqlockview channel(1:8) |
| Different domain dpll phaselock observability | Control | CONTROL_CONF_DPLL_PHASELOCK_SEL [2:0] MULT | Select DPLL phaselockview channel(1:8) |
| Different domain dpll tinitz observability | Control | CONTROL_CONF_DPLL_TINITZ_SEL [2:0] MULT | Selects to observe DPLL tinitzview channel (1:8) |
| Different domain dpll tenable observability | Control | CONTROL_CONF_DPLL_TENABLE_SEL [2:0] MULT | Selects to observe DPLL tenableview channel (1:8) |
| Different domain dpll tenablediv observability | Control | CONTROL_CONF_DPLL_TENABLEDIV_SEL [2:0] MULT | Selects to observe DPLL tenabledivview channel (1:8) |
| Different domain dpll bypassack observability | Control | CONTROL_CONF_DPLL_BYPASSACK_SEL [2:0] MULT | Selects to observe DPLL bypassackview channel (1:8) |
| Different domain dpll idle observability | Control | CONTROL_CONF_DPLL_IDLE_SEL [2:0] MULT | Selects to observe DPLL idleview channel (1:8) |

NOTE: Features configured in the following registers are limited to the hardware observability signals, hw_dbg i (where i = 0 to 31), multiplexed and propagated in the CORE power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL](#)[i] SELECT = 0b1).

- [CONTROL_CORE_CONF_DEBUG_SEL_TST_0](#) through [CONTROL_CORE_CONF_DEBUG_SEL_TST_31](#)
- [CONTROL_CONF_CLK_SEL0](#)[2:0] MULT through [CONTROL_CONF_CLK_SEL2](#)[2:0] MULT
- [CONTROL_CONF_SDMA_REQ_SEL0](#) through [CONTROL_CONF_SDMA_REQ_SEL3](#)
- [CONTROL_CONF_DPLL_FREQLOCK_SEL](#)
- [CONTROL_CONF_DPLL_TINITZ_SEL](#)
- [CONTROL_CONF_DPLL_PHASELOCK_SEL](#)
- [CONTROL_CONF_DPLL_TENABLE_SEL](#)
- [CONTROL_CONF_DPLL_TENABLEDIV_SEL](#)
- [CONTROL_CONF_DPLL_BYPASSACK_SEL](#)
- [CONTROL_CONF_DPLL_IDLE_SEL](#)

These options do not apply to the hardware observability signals, hw_dbg i (where i = 0 to 31), which at the general control module level are muxed in the WKUP power domain ([CONTROL_DEBOBS_FINAL_MUX_SEL](#)[i] SELECT = 0b0).

The `CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[0]` MODE bit (where $i = 0..31$) provides the option to choose between the observation of device power and reset manager signals or observation of clock manager 1-related signals. If `CONTROL_WKUP_CONF_DEBUG_SEL_TST_i[0] = 0b1`, the `hwobs_int_prm_i` signal is selected. Otherwise, the `hwobs_int_cm1_i` signal is output.

NOTE: The CM1 and PRM observable signals are multiplexed in the WKUP power domain.

18.4.11.4 Observability Signals Multiplexing at Device Control Module Level

The pads used for the hardware debug must be properly configured by selecting the hardware debug function (hw_dbgn) of the pad.

18.4.11.4.1 Observability Signals Muxed on Pads in CORE Power Domain

To map the hw_dbg0 through hw_dbg19 signals to their associated external device pads in the CORE power domain, set the related MUXMODE fields within [CONTROL_CORE_PAD0_SYS_BOOT5_PAD1_DPM_EMU0](#) through [CONTROL_CORE_PAD0_DPM_EMU19](#) padconfiguration registers to 0b110 (Mode 6).

To make the remaining signals, hw_dbg20 through hw_dbg31, available at their corresponding device pads in the CORE power domain, set the MUXMODE fields within the [CONTROL_CORE_PAD0_CAM_GLOBALRESET_PAD1_USBB1_ULPITLL_CLK](#) through [CONTROL_CORE_PAD0_USBB1_ULPITLL_DAT7_PAD1_USBB1_HSIC_DATA](#) padconfiguration registers to 0b110 (mode 6).

For more information, see [Table 18-9](#).

For more information about hardware observability configuration, see [Table 18-111](#).

NOTE: The hw_dbg i signals (where i = 0 to 31), which are multiplexed and propagated in the CORE power domain, are not visible when the device is set into off mode (PD_CORE supply switched off).

18.4.11.4.2 Observability Signals Muxed on Pads in WKUP Power Domain

To have the hw_dbg1 through hw_dbg13 signals multiplexed on the WKUP power domain pads, set MuxMode = 0x6 in the following SYSCONF_PADCONF_WKUP registers:

- [CONTROL_WKUP_PAD0_GPIO_WK0_PAD1_GPIO_WK1](#) through [CONTROL_WKUP_PAD0_GPIO_WK2_PAD1_GPIO_WK3](#)[31:16] to have the hw_dbg1–hw_dbg4 signals output on the gpio_wk0–gpio_wk3 device pads, respectively.
- [CONTROL_WKUP_PAD0_GPIO_WK4_PAD1_SR_SCL](#)[15:0] to have the hw_dbg5 signal output on the gpio_wk4 device pad
- [CONTROL_WKUP_PAD0_FREQ_CLK0_OUT_PAD1_FREQ_CLK3_REQ](#) through [CONTROL_WKUP_PAD0_FREQ_CLK3_OUT_PAD1_FREQ_CLK4_REQ](#) to have the hw_dbg6–hw_dbg9 signal output on the freq_clk0_out, freq_clk3_req, freq_clk3_out, and freq_clk4_req device pads, respectively.
- [CONTROL_WKUP_PAD0_FREQ_CLK4_OUT_PAD1_SYS_32K](#)[15:0] to have the hw_dbg10 signal output on the freq_clk4_out device pad
- [CONTROL_WKUP_PAD0_SYS_PWR_REQ_PAD1_SYS_PWRON_RESET_OUT](#)[31:16] to have the hw_dbg11 signal output on the sys_pwrn_reset_out device pad
- [CONTROL_WKUP_PAD0_SYS_BOOT6_PAD1_SYS_BOOT7](#) to have the hw_dbg12 and hw_dbg13 signals output on the sys_boot6 and sys_boot7 device pads, respectively.

For more information, see [Table 18-8](#).

For more information about hardware observability configuration, see [Table 18-111](#).

NOTE: If multiplexed on corresponding device pads in the WKUP power domain, the hw_dbg i signals (where i = 0 to 31), which are multiplexed and propagated in the WKUP power domain, can be observed even if the device goes into off mode.

18.4.11.5 Observability Signals Sourced at Module Level

Observable signals coming from within different device subsystems are mapped to general core control and general wakeup control observability inputs. Additional multiplexing is also implemented inside some of the observable modules (See [Figure 18-18](#)).

18.4.11.5.1 Dual Cortex-A9 Subsystem Observable Signals

Table 18-21 through Table 18-29 show the Cortex-A9 MPU subsystem observable signals available in 8 functional multiplexing modes. The mode is selected at the general core control module level by programming the `CONTROL_DEBOBS_MMR_MPU[3:0]` SELECT bit field. The SELECT values in range (0x8–0xF) are reserved for future use.

The POPROFILING_EVENT2PRM bus signals, observable in modes 0, 1, 2, and 3, monitor the power states of the CPU. There are 6 status bits per Cortex-A9 CPU0 and CPU1, respectively. The encoding of the status bits is described in [Table 18-25](#).

POPROFILING_EVENT2PRM[5:0] are the status bits for CPU0, and POPROFILING_EVENT2PRM [11:6] are the status bits for CPU1.

18.4.11.5.3 Display Subsystem Observable Signals

The display subsystem observable signals described in [Table 18-31](#) are directly mapped to display subsystem observability inputs of the SYSCTRL_GENERAL_CORE module, and no additional multiplexing is performed inside the display subsystem wrapper.

Table 18-31. Observability Signals at Display Subsystem Level

| SYSCTRL_GENERAL_CORE Observability Inputs Tied to Signals Inside Display Subsystem | Display Subsystem Observable Signals Mapped to SYSCTRL_GENERAL_CORE Observability Inputs | Signal Description | Logical Value Meaning |
|-------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|-----------------------------------------------------------------------------|
| hwobs_dssvenctvdetgp | DSS_VENC_TVDETP | Display subsystem VENC tvdetgp | Active high pulse to detect the TV connection |
| hwobs_dssdacpwrndaczcvbs_y | DSS_DAC_PWR_DND ACZCVBS/Y | Display subsystem DAC pwrnd dac zcvbs_y –Power down for DAC Y | 0: DAC Y put in power-down mode 1: DAC Y put in ACTIVE state |

| hwobs_dssdacpwrndbgz | DSS_DAC_PWR_DNB GZ | Display subsystem DAC pwrnd bgz – Band gap power down for DAC | 0: DAC Bandgap put in power-down mode 1: DAC Bandgap put in ACTIVE state |

18.4.11.5.4 DSP Subsystem Observable Signals

The DSPSS.DSPSS_MMU_GPR register provides mux control for hardware observability signals exported at the DSPSS boundary to the general control module. Interrupts, DMA requests, and other events can be seen on the PO_HW_DBG_OUT bus. The DSPSS.DSPSS_MMU_GPR register provides mux controls for selecting the appropriate 32-bit value to be output on the PO_HW_DBG_OUT signal bus. The mux values and associated signals that can be observed on the PO_HW_DBG_OUT are described in [Chapter 20, Memory Management Units](#). Setting the DSPSS.DSPSS_MMU_GPR[15] FORCE_IDLE_REQ bit initiates idle request/acknowledgment protocol with various blocks; the acknowledge information can be observed when HWDEBUG_MUX = 4'b1110.

All interrupts into DSPSS can be observed by setting the DSPSS.DSPSS_MMU_GPR[3:0] HWDEBUG_MUX bit field to 0x6, 0x7, 0x8, and 0x9. All interrupts to the INTC, which includes external and internal interrupts, can be seen by setting the HWDEBUG_MUX values to 0x2, 0x3, 0x4, and 0x5. DMA requests can be seen when the HWDEBUG_MUX values are set to 0xA and 0xB.

DPLL_IVA and the associated HSDIVIDER values can be seen by values of 0x0, the default reset value. DSPSS raw CD0 clock is sent out without any division. Other clocks are divided by 32.

The DSPSS.DSPSS_MMU_GPR[15] FORCE_IDLE_REQ bit must be used only for observability purposes, not in functional mode. When set, the FORCE_IDLE_REQ bit causes IDLE requests to be sent to various components inside the DSPSS, and idle acknowledgment is displayed when the value of the HWDEBUG_MUX[3:0] bit field is 4'b1110; the signals listed can then be checked to determine which component is not idle.

NOTE: Once this feature is used, FORCE_IDLE_REQ must be set to 0 before continuing the observability process.

[Table 18-32](#) through [Table 18-38](#) show DSP subsystem observable signals available in 8 multiplexing modes. The mode is selected at the general control module level by setting the DSPSS_MMU_GPR[3:0] HWDEBUG_MUX bit field.

18.4.11.5.5 ABE Subsystem Observable Signals

The audio back-end observable signals described in [Table 18-39](#) are directly mapped to the ABE dedicated observability inputs(hwobs_int_abe[31:0] of the SYSCTRL_GENERAL_CORE module) and no additional multiplexing is performed inside the ABE subsystem.

Table 18-39. Observability Signals at ABE Subsystem Level

| ABE Subsystem | ABE Level Observability Signals | Signal Description | Logical Value Meaning |
|----------------------|---------------------------------|--------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| hwobs_int_abe[31:26] | – | – | – |
| hwobs_int_abe[25:24] | OPP_DIV | OPP DIVIDER bit[1:0] | – |
| hwobs_int_abe[23] | AESS_to_MPU_IRQ | IRQ sent from AESS to MCU. See Chapter 12, ABE . | – |
| hwobs_int_abe[22] | AESS_to_DSPSS_IRQ | IRQ sent from AESS to DSP. See Section 5.3.7, Interrupt Requests , and Chapter 12, ABE . | – |
| hwobs_int_abe[21] | Reserved | – | – |
| hwobs_int_abe[20] | GPT_WDT_PWM_INP | PWM received from the GPTIMER or watchdog (OR) | – |
| hwobs_int_abe[19] | AESS_DMAREQ_ALL | (Logical OR with all DMA req out) | High while outgoing DMA requests from audio engine have not been acknowledged by the host. |
| hwobs_int_abe[18] | AESS_DMAREQ_PER | (Logical OR with all DMA req coming from the peripheral) | High when incoming DMA requests from audio engine are still to be served. |

Table 18-39. Observability Signals at ABE Subsystem Level (continued)

| ABE Subsystem | ABE Level Observability Signals | Signal Description | Logical Value Meaning |
|---------------------|---------------------------------|-------------------------|----------------------------------------------------------------------------------------------------|
| hwobs_int_abe[17] | AESS_IDLEPO | The PO_IDLE AESS output | High when the audio engine executes a wait until an activation of the PI_WAKEUP pin has been done. |
| hwobs_int_abe[16:0] | RESERVED | - | - |

18.4.11.5.6 USBOTGHS Subsystem Observable Signals

One of the general wakeup control observability inputs can be mapped to the USBOTGHS "start of frame signal" (hsubotg_sofpulse by setting [CONTROL_CORE_CONF_DEBUG_SEL_TST_11\[3:0\] MODE = 0x1](#)).

18.4.11.5.7 CM2 Subsystem Observable Signals

The SYSCTRL_GENERAL_CORE observability inputs hwobs_int_cm2(i) (where i = 0...31) are mapped to the signals debugcm2(i) (where i = 0...31) coming out of the PRCM submodule, Clock Manager 2 (CM2).

Local multiplexing controls at the CM2 level reside in the CM2_DEBUG_CFG register. The CM2 observability output signals are driven on the debugcm2(0) through debugcm2(7) lines. A certain mux set is selected by programming the CM2_DEBUG_CFG[7:0] SEL0 bit field. The remaining debugcm2(8) through debugcm2(31) lines are reserved for future use. For more information about the CM2 observability source select field, see [Section 3.11.30.1, INTRCONN_SOCKET_CM2 Register Summary](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-40](#) provides different details about the signals inside CM2 that can be monitored on device hw_dbg pins.

18.4.11.5.8 CM1 Subsystem Observable Signals

The general wakeup control observability inputs hwobs_int_cm1(i) (where i = 0...31) are mapped to the signals debugcm1(i) (where i = 0...31) coming out of the PRCM submodule, clock manager 1 (CM1).

Local multiplexing controls at the CM1 level reside in the CM1_DEBUG_CFG register. The CM1 observability output signals are driven on the debugcm1(0) through debugcm1(7) lines. A certain mux set is selected by programming the CM1_DEBUG_CFG[6:0] SEL0 bit field. The remaining debugcm1(8) through debugcm1(31) lines are reserved for future use. For more information about the CM1 observability source select field, see [Section 3.11.22.1, INTRCONN_SOCKET_CM1 Register Summary](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-41](#) provides different details about the signals inside CM1 that can be monitored on device hw_dbg pins.

18.4.11.5.9 PRM Subsystem Observable Signals

The general wakeup control observability inputs hwobs_int_prm(i) (where i = 0...31) are mapped to the signals debugprm(i) (where i = 0...31) coming from the power reset manager (PRM) submodule.

Local multiplexing controls at the PRM level reside in the PRM_DEBUG_CFG register. The PRM observability output signals are driven on the debugprm(0) through debugprm(7) lines. A certain mux set is selected by programming the PRM_DEBUG_CFG[6:0] SEL0 bit field. The remaining debugprm(8) through debugprm(31) lines are reserved for future use. For more information about the PRM observability source select field, see [Section 3.11.2.1, INTRCONN_SOCKET_PRM Register Summary](#) in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 18-42](#) provides different details about the signals inside the PRM that can be monitored on device hw_dbg pins.
