| Description | Peripheral Identification register - allows the user software to differentiate between the two ARM Cortex-M3 processors (two CPUs). The same piece of code running on the two CPUs can result in different execution (in example branch to different location) depending on what address is stored in the register. The address is stored by the BIOS code. The register cannot be accessed when the BIOS code is running (used). | | |

Imaging Subsystem

This chapter gives a top-level overview of the imaging subsystem (ISS) in the device.

For a full description of SIMCOP module, see [Section 8.4, ISS:Still Image Coprocessor](#).

For a full description of ISS interfaces and Interconnects, that is CSI2, CCP2, timing control, burst translation engine, and circular buffer modules, see [Section 8.2, ISS:Interfaces](#).

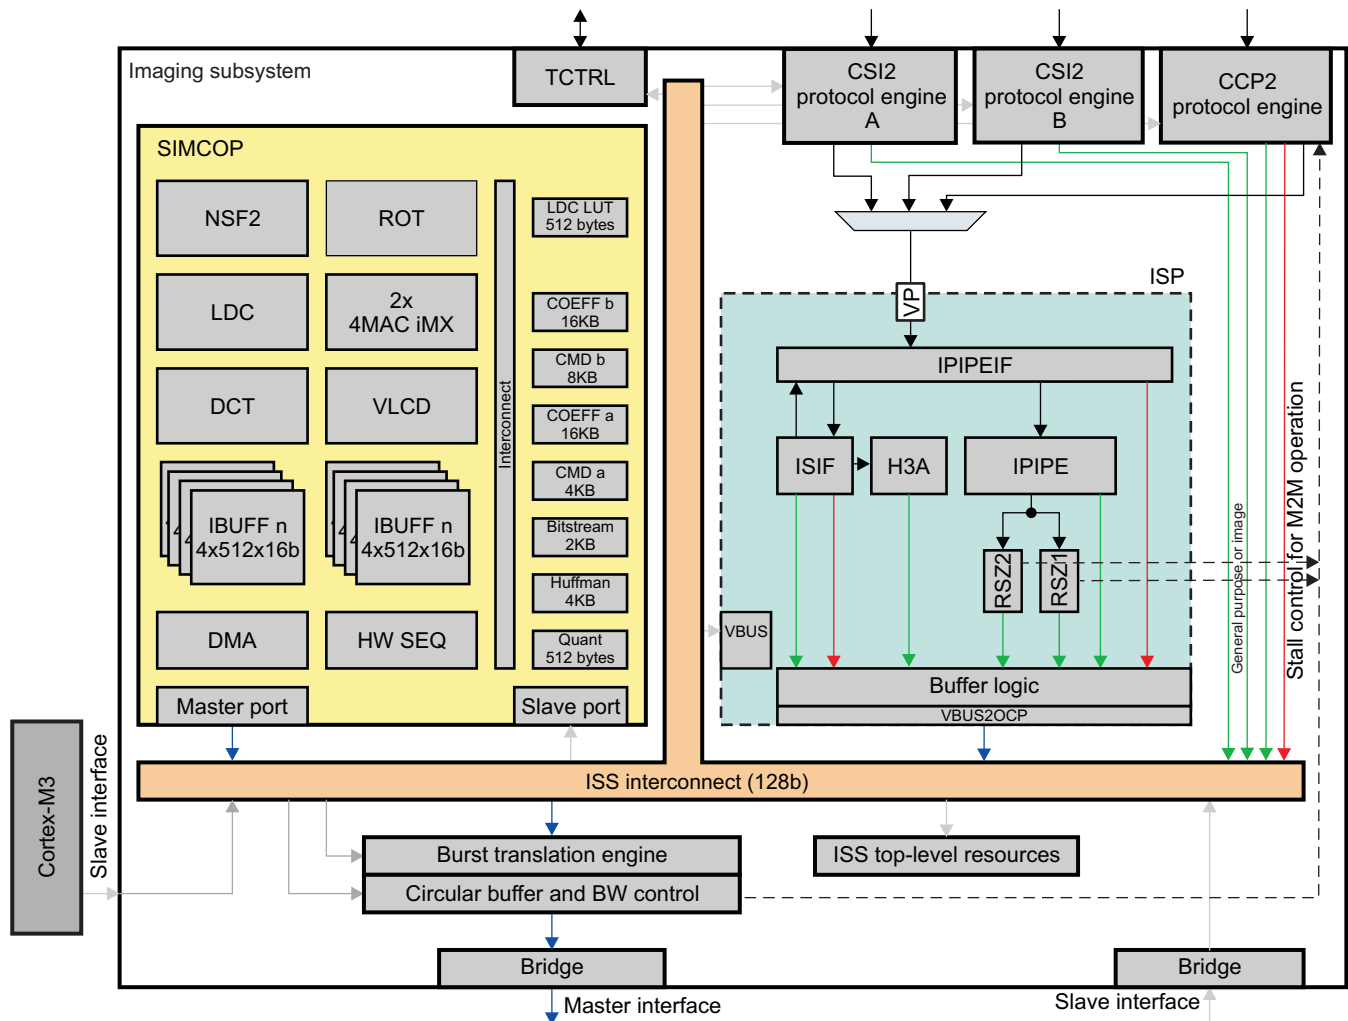

For a full description of ISS ISP, see [Section 8.3, ISS:Image Signal Processor](#).

| Topic | Page |
|----------------------------------------------|-------------|
| 8.1 ISS Overview | 1476 |
| 8.2 ISS Interfaces | 1512 |
| 8.3 ISS ISP | 1776 |
| 8.4 ISS Still Image Coprocessor | 2224 |

8.1 ISS Overview

The imaging subsystem (ISS) deals with the processing of the pixel data coming from an external image sensor, data from memory (image format encoding and decoding can be done to and from memory), or data from SL2 in IVA-HD for hardware encoding. With its subparts, such as interfaces and interconnects, image signal processor (ISP), and still image coprocessor (SIMCOP), the ISS is a key component in the following multimedia applications: camera viewfinder, video record, and still image capture. [Figure 8-1](#) is an overview of the ISS.

Figure 8-1. ISS Overview

camss-351

The direction of the arrows shows the command flow direction: it goes from the master (initiator) to the slave (target). The following color conventions are used for the connections:

- Blue: Bidirectional, 128-bit-wide interface data connection
- Green: Write (ISS -> system memory) data connection. Either 64-bit interface, 128-bit interface, or 32-bit MTC (inside ISP5).
- Red: Read (system memory to ISS) data connection. 128-bit interface port or 32-bit MTC (inside ISP5).
- Gray: 32-bit interface configuration connection
- Solid black: Video port and camera interface related signals
- Dotted black: Data flow stall control signal. Used to slow down ISP for memory-to-memory operation.

the ISS is mainly composed of CCP2 and CSI2-A, CSI2-B camera interfaces, an ISP, and a block-based imaging accelerator (SIMCOP).

The ISS is designed so that it can reach high throughput and low latency with large image sensors. In high-performance mode, the ISS supports a pixel throughput of 200 MPix/s.

Two programmable image processors, iMX4, are included in the SIMCOP subsystem to add further flexibility to implement new algorithms or in case new issues are encountered with the image sensors. The iMX4 processors are also open for third-party algorithms.

The ISS is tightly coupled with a low-interrupt latency microprocessor unit (MPU) subsystem (Cortex™-M3 MPU) that runs a real-time operating system (OS) to reach optimal performance. Mainly, the Cortex-M3 MPU can quickly change the ISS configuration during frame blanking periods and run some sequencing tasks.

The ISS targets the following major use cases:

- Viewfinder with digital zoom, video stabilization, and rotations
- Up to 1080p video record at 30 fps with digital zoom, video stabilization, and rotation
- Up to 16 MPix still image capture with digital zoom and rotation
 - High performance mode: Up to 200 MPix/s throughput
 - High quality and low light modes: Up to 50 MPix/s throughput
- Still image capture during video record

NOTE: The ISS is not limited to 16 Mpix. Higher resolution can be achieved through multiple passes.

NOTE: For a detailed list of features of a certain submodule, see the related subsection.

The ISS offers the following features:

- SIMCOP:
 - Memory-to-memory operation
 - JPEG encode and decode hardware acceleration
 - High-ISO noise filtering (NSF 2.0)
 - Rotation accelerator
 - Warping accelerator
 - Lens distortion correction (YUV space)
 - General-purpose (GP) imaging accelerator (2x iMX4)
 - Direct memory access (DMA) controller
 - Hardware sequencer
- ISP:
 - On-the-fly or memory-to-memory processing
 - Up to 200-MHz pixel throughput
 - Statistic data collection
 - Image pipe interface front-end raw data processing
 - RGB and YUV data processing through ISIF and IPIPE
 - Hardware 3A (H3A) statistics block for real-time auto focus (AF), auto exposure (AE), and auto white balance (AWB)
 - Two image continuous real-time resizers
 - Video port (VP) for interfacing with the receivers and directing data to the ISP
- ISS interfaces:
 - 128-bit-wide data interface to the level 3 (L3) interconnect
 - Burst translation engine (BTE) tightly coupled with the TILER to support efficient rotation
 - Circular buffer for linear space, physically located in memory

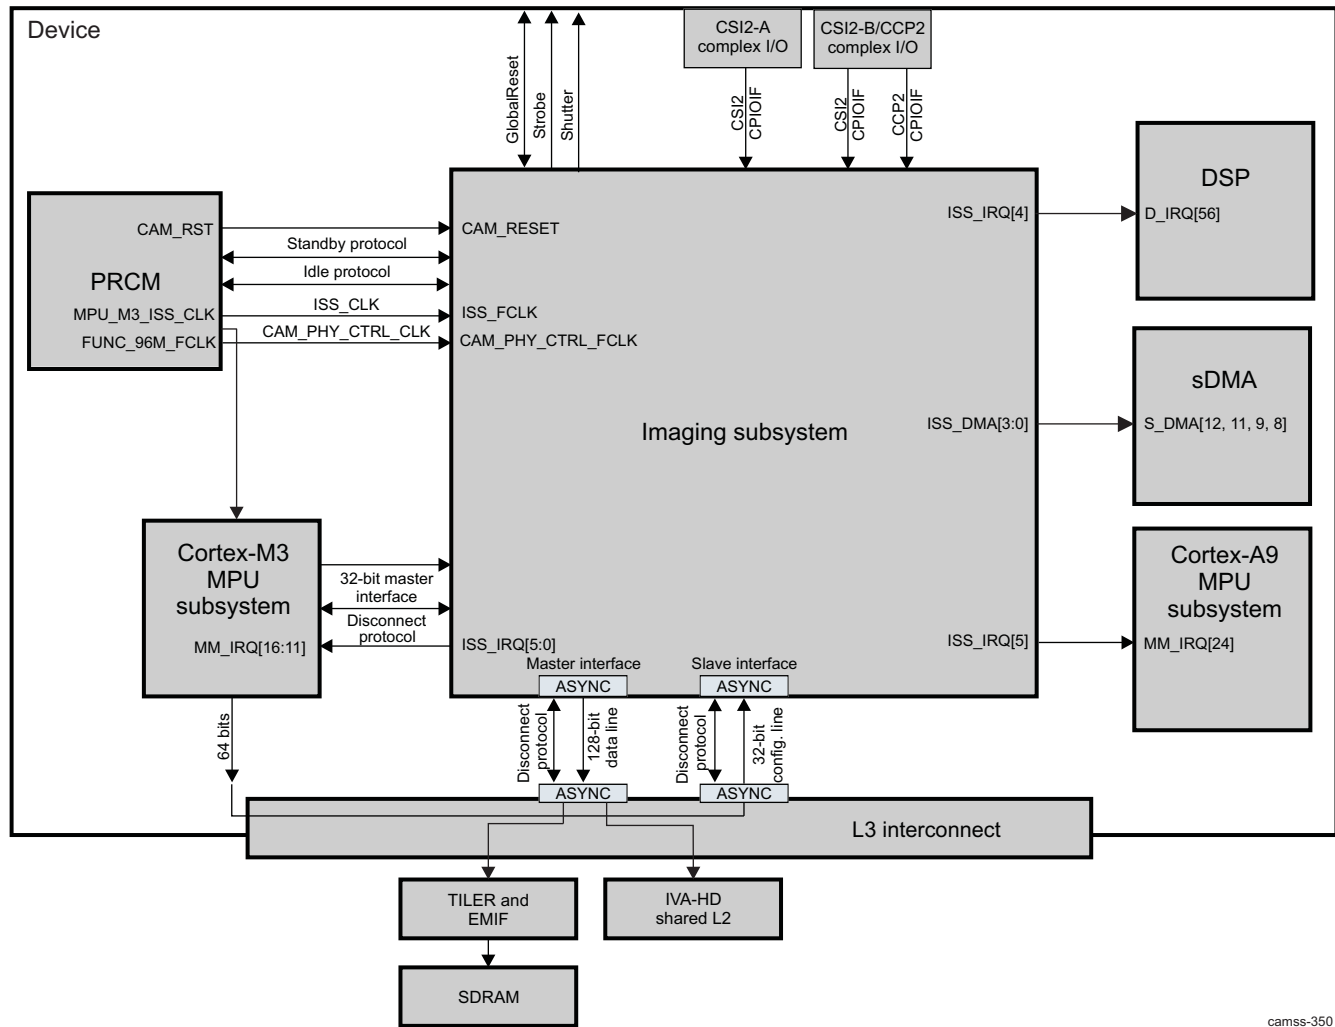

- The ISS relies on the centralized memory management unit (MMU) feature of the DMM. See [Chapter 20, Memory Management Unit](#), and [Chapter 15, Memory Subsystem](#).
- Two CSI2 camera interfaces: CSI2-A (primary) and CSI2-B (secondary)
- CCP2 camera interface (secondary). Compatible with the *SMIA CCP2 Specification v1.0* and the *MIPI CSI1 Specification*.
- System memory data read-back port (supported by the CCP2 protocol engine module)

8.1.1 ISS Integration

This section describes the integration of the module in the device, including information about clocks, resets, and hardware requests.

Figure 8-2 shows the ISS integration.

Figure 8-2. ISS Integration

camss-350

NOTE: For more information about the IDLE hardware handshake and wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

This section gives an overview of typical uses of the module. For more information about the relationship of the power, reset, and clock management (PRCM) module to the ISS clocks and the reset settings, see the detailed functional description in [Chapter 3, Power, Reset, and Clock Management](#).

The ISS is part of ISS hardware and power management, which comprises the Cortex-M3 MPU, ISS, and a clock generator. These are all independent power domains. The ISS is part of the CAM power domain.

The PRCM module provides a single clock (MPU_M3_ISS_CLK) to ISS power management. This clock generates the clocks for the Cortex-M3 MPU, ISS, and the bridges to L3.

The ISS also supports software reset. A software reset has the same function as a hardware reset except that it does not reset the power-management protocols.

When enabled, MPU_M3_ISS_CLK is gated to provide ISS_CLK, which, after entering the ISS boundary, is named ISS_FCLK. MPU_M3_ISS_CLK is provided as long as the Cortex-M3 MPU or ISS modules within the ISS require it.

CAM_PHY_CTRL_CLK is gated from FUNC_96M_FCLK, which comes from the PRCM module. When enabled and inside the ISS boundary, it is called CAM_PHY_CTRL_FCLK.

NOTE: For more information about the device clocks and how they are handled by the PRCM module before going into the ISS, see [Section 3.6.3.2.4, CM2 Clock Generator](#), in [Chapter 3, Power, Reset, and Clock Management](#).

[Table 8-1](#) through [Table 8-3](#) summarize the integration of the module in the device.

Table 8-1. ISS Integration Attributes

| Module Instance | Attributes | | |
|-----------------|--------------|--------------------|--------------|
| | Power Domain | Wake-Up Capability | Interconnect |
| ISS | PD_CAM | No | |

Table 8-2. ISS Clocks and Resets

| Clocks | | | | |

Table 8-3. ISS Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|----------------|--------------------------------------------------------|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| ISS | ISS_IRQ4 | D_IRQ_56 | DSP INTC | Interrupt generated by ISS to DSP |
| | ISS_IRQ5 | MM_IRQ_24 | Cortex-A9 INTC | Interrupt generated by ISS to Cortex-A9 |
| | ISS_IRQ0 | MM_IRQ_11 | Cortex-M3 INTC | Interrupt generated by ISS to Cortex-M3 |
| | ISS_IRQ1 | MM_IRQ_12 | Cortex-M3 INTC | Interrupt generated by ISS to Cortex-M3 |
| | ISS_IRQ2 | MM_IRQ_13 | Cortex-M3 INTC | Interrupt generated by ISS to Cortex-M3 |
| | ISS_IRQ3 | MM_IRQ_14 | Cortex-M3 INTC | Interrupt generated by ISS to Cortex-M3 |
| | ISS_IRQ4 | MM_IRQ_15 | Cortex-M3 INTC | Interrupt generated by ISS to Cortex-M3 |
| | ISS_IRQ5 | MM_IRQ_16 | Cortex-M3 INTC | Interrupt generated by ISS to Cortex-M3 |
| DMA Requests | | | | |
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| ISS | ISS_DMA0 | S_DMA_8 | sDMA | Signal connected to the sDMA directly provided by ISP. |
| | ISS_DMA1 | S_DMA_9 | sDMA | Signal connected to the sDMA directly provided by ISP |
| | ISS_DMA2 | S_DMA_11 | sDMA | Signal connected to the sDMA directly provided by ISP |
| | ISS_DMA3 | S_DMA_12 | sDMA | Signal connected to the sDMA directly provided by ISP |

8.1.1.1 ISS PRCM Interface Integration

8.1.1.1.1 ISS Clock Domains

The ISS has five asynchronous clock domains. Most of the logic uses ISS_FCLK; the other clock domains are used for interfaces.

[Table 8-4](#) provides a high-level view of clocks. The frequencies provided are maximum values.

Table 8-4. ISS Local Clock Domains

| Name | Description |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PCLK | The CSI2-A, CSI2-B, and CCP2 modules have video port outputs, each having its own pixel clock. These pixel clocks are generated from the functional clock (ISS_FCLK). All three pixel clock sources are multiplexed into one clock provided to the ISP. |
| CSI2_A_BC | Byte clock provided by the CSI2-A complex I/O. Used by the CSI2-A receiver. |
| CSI2_B_BC | Byte clock provided by the CSI2-B/CCP2 complex I/O. Used by the CSI2-B receiver. |
| CCP2_BC | Clock provided by the CCP2 complex I/O. Used by the CCP2 protocol engine. |
| ISS_FCLK | Functional clock provided by ISS_CLK from the PRCM module. It is used by all ISS submodules and ISS top-level resources. |
| CAM_PHY_CTRL_FCLK | Functional clock provided by the PRCM module. It is used by the CSI2-A and CSI2-B/CCP2 complex I/Os. |

To save power, the ISS can divide the received functional clock (ISS_CLK) by 2 or 4 from [ISS_CTRL\[4:5\]](#) ISS_CLK_DIV. The configuration clock is always half the functional clock.

The functional clock of some submodules can be cut by software to reduce power consumption by cutting off or turning on the modules from the [ISS_CLKCTRL](#) register. Also, the pixel clocks sent by submodules to ISP can be cut off from [ISS_CLKCTRL](#) VPORT_x_CLK.

8.1.2 ISS Functional Description

This section provides only a top-level overview of the ISS. The ISS submodules are described in: [Section 8.4, ISS:SIMCOP](#), [Section 8.2, ISS:interfaces](#), and [Section 8.3, ISS:ISP](#).

The following section describes the ISS power-management mechanisms and gives an introduction to and a functional description of the ISP submodules.

8.1.2.1 ISS Interrupts

[Table 8-5](#) lists the events generated by the submodules and the top level of the ISS.

Each event that generates an interrupt can be individually enabled by setting the appropriate bit in the [ISS_HL_IRQENABLE_SET_i](#) register. The interrupt is disabled by setting the appropriate bit in the [ISS_HL_IRQENABLE_CLR_i](#) register.

When an event occurs, the corresponding bit in the [ISS_HL_IRQSTATUS_RAW_i](#) register is set regardless of whether or not the event is enabled. Bits in the [ISS_HL_IRQSTATUS_i](#) registers are set only when an enabled event occurs.

Software can clear a pending HS_VS_IRQ event by setting the [ISS_HL_IRQSTATUS_i\[17\]](#) HS_VS_IRQ bit. Events generated by submodules are automatically cleared at the ISS level when they are cleared at the submodule level.

8.1.2.1.1 ISS Interrupt Merger

The ISS merges the following eight interrupt sources into six physical interrupt lines. All six lines support level and pulse modes.

Table 8-5. ISS Interrupts

| Interrupt | Source | Description |
|-----------------|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ISP_IRQ[3:0] | ISP | Interrupt generated by the ISP ⁽¹⁾ |
| CSIA_IRQ | CSI2-A | Interrupt generated by the CSI2-A receiver ⁽¹⁾ |
| CSIB_IRQ | CSI2-B | Interrupt generated by the CSI2-B receiver ⁽¹⁾ |
| CCP2_IRQ[3:0] | CCP2 | Interrupt generated by the CCP2 receiver ⁽¹⁾ |
| CCP2_IRQ[8] | CCP2 | Interrupt generated by the CCP2 receiver ⁽¹⁾ |
| CBUFF_IRQ | CBUFF | Interrupt generated by the circular buffer ⁽¹⁾ |
| BTE_IRQ | BTE | Interrupt generated by the BTE ⁽¹⁾ |
| SIMCOP_IRQ[3:0] | SIMCOP | Interrupt generated by SIMCOP |
| HS_VS_IRQ | ISS | HS or VS synchronization event. This event is triggered if a rising or falling edge is detected on the HS or VS signal. The rising or falling edge and the HS or VS signal selection are chosen using the ISP_CTRL[0:1] SYNC_DETECT bit field. |

⁽¹⁾ For more information, see [Section 8.1.2.1.2, ISS Submodule Interrupts](#).

Software can select which interrupt sources are routed to each output line (ISS_IRQ[0:5]). All six physical interrupt outputs have equivalent functions. Software can use different interrupt lines to group events together by type and therefore reduce interrupt latencies. Typically, one interrupt line is used for low-priority events (errors), and the other interrupt lines are used for high-priority events (for example, SIMCOP sequencing and end-of-frame events to trigger configuration load). The ISS internal interrupt request (IRQ) merger (see [Figure 8-3](#)) relies only on level interrupts provided by submodules. Pulse interrupts provided by submodules are ignored. Typically, all of the interrupts are routed to the Cortex-M3 running the camera driver. In addition, one interrupt is routed to Cortex-A9, which may run the imaging software. Software does not need to clear events from submodules at the ISS level: it clears only the events at the submodule level; the IRQ merger automatically clears the IRQ at this level.

NOTE: Only the HS_VS_IRQ top-level event is cleared at the ISS level.

Figure 8-3. ISS Interrupt Merger

camss-702u

NOTE: For more information about mapping the six lines to the outside ISS device modules, see [Table 8-3](#).

Only the ISP, SIMCOP, and HL ISS merger IRQ lines are configurable. Each interrupt can be mapped to the required line. This is not the case with CCP2 where, for example, LC01 is hardwired to line0 and line1.

8.1.2.1.2 ISS Submodule Interrupts

The ISS shown in [Figure 8-3](#) and listed in [Table 8-3](#) can generate six interrupts.

8.1.2.1.2.1 ISS ISP Interrupts

[Table 8-6](#) summarizes events that cause ISP interrupts.

Table 8-6. ISS ISP Interrupts

| Event and Register ⁽¹⁾ | Description |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ISP5_IRQENABLE_SET_i[[31] OCP_ERR_IRQ | An interface port error has been received on the ISP master port. |
| ISP5_IRQENABLE_SET_i[29] IPIPE_INT_DPC_RNEW1 | HD interrupt signal to indicate the need to renew the defect pixel correction (DPC) table with new entries. The second 128 entries in the DPC table must be updated when this event triggers. This event is triggered when the 255th entry in the look-up table (LUT) is used. This interrupt is not synchronous to the HD signal. |
| ISP5_IRQENABLE_SET_i[28] IPIPE_INT_DPC_RNEW0 | VD interrupt signal to indicate the need to renew the DPC table with new entries. The first 128 entries in the DPC table must be updated when the event triggers. This event is triggered when the 127th entry in the LUT is used. This interrupt is not synchronous to the HD signal. |
| ISP5_IRQENABLE_SET_i[27] IPIPE_INT_DPC_INI | Interrupt to signal the need to initialize the DPC table. The DPC table contains two tables of 128 entries. When this signal is used, software must ensure that the 256 table entries are updated with the DPC information. |
| ISP5_IRQENABLE_SET_i[25] IPIPE_INT_EOF | End of frame interrupt signal |
| ISP5_IRQENABLE_SET_i[24] H3A_INT_EOF | End of frame interrupt signal |
| ISP5_IRQENABLE_SET_i[22] RSZ_INT_EOF1 | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[23] RSZ_INT_EOF0 | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[19] RSZ_FIFO_IN_BLK_ERR | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[18] RSZ_FIFO_IN_OVF | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[17] RSZ_INT_CYC_RZB | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[16] RSZ_INT_CYC_RZA | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[15] RSZ_INT_DMA | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[14] RSZ_INT_LAST_PIX | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[13] RSZ_INT_REG | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[12] H3A_INT | Interrupt generated by the AF and AE/AWB blocks inside the H3A module. It indicates the end of processing a frame and is active high for one configuration bus clock cycle. |
| ISP5_IRQENABLE_SET_i[11] AF_INT | AF inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish. |
| ISP5_IRQENABLE_SET_i[10] AEW_INT | AEW inside generates an interrupt at the end of processing frame; a third interrupt is generated at the same time as the last process to finish. |
| ISP5_IRQENABLE_SET_i[9] IPIPEIF_IRQ | IPIPEIF module interrupt is generated at the start position of a frame and is active high for one configuration bus clock cycle. |
| ISP5_IRQENABLE_SET_i[8] IPIPE_INT_HST | IPIPE module interrupt is generated when histogram is done. |
| ISP5_IRQENABLE_SET_i[7] IPIPE_INT_BSC | IPIPE module interrupt is generated when boundary signal calculation is done. |
| ISP5_IRQENABLE_SET_i[6] IPIPE_INT_DMA | IPIPE module interrupt is issued when the SDRAM transfer of boxcar is done. At this time, IPIPE EOF is sent to buffer logic. |
| ISP5_IRQENABLE_SET_i[5] IPIPE_INT_LAST_PIX | IPIPE module interrupt is issued when the last pixel of a frame comes into IPIPE. |
| ISP5_IRQENABLE_SET_i[4] IPIPE_INT_REG | IPIPE module interrupt is issued when the register update of the module is allowed. |
| ISP5_IRQENABLE_SET_i[3] ISIF_INT_3 | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[2] ISIF_INT_2 | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[1] ISIF_INT_1 | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET_i[0] ISIF_INT_0 | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET2_i[0] H3A_OVF | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET2_i[1] IPIPEIF_UDF | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET2_i[2] IPIPE_BOXCAR_OVF | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET2_i[3] ISIF_OVF | See Section 8.1.3 and Section 8.3.5 . |
| ISP5_IRQENABLE_SET2_i[4] IPIPE_HST_ERR | See Section 8.1.3 and Section 8.3.5 . |

⁽¹⁾ i = 0 to 3

8.1.2.1.2.2 ISS CSI2-A and CSI2-B Complex I/O Interrupts

Table 8-7 lists the event generation of the CSI2-A and CSI2-B receivers through the CSI2 interrupt status and interrupt enable registers. The events are checked for status using the CSI2_IRQSTATUS and CSI2_IRQENABLE registers.

Table 8-7. ISS CSI2-A and CSI2-B Interrupts

| Event and Register | Description |
|------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CSI2_IRQENABLE[14] OCP_ERR_IRQ | Interface port error |
| CSI2_IRQENABLE[13] SHORT_PACKET_IRQ | Short packet reception (other than sync events: line start, line end, frame start, and frame end; only data types from 0x8 to 0xF are considered) |
| CSI2_IRQENABLE[12] ECC_CORRECTION_IRQ | ECC was used to correct a 1-bit error (short packet only). |
| CSI2_IRQENABLE[11] ECC_NO_CORRECTION_IRQ | ECC was not used to correct the header because the error is larger than 1 bit (short and long packets). |
| CSI2_IRQENABLE[9] COMPLEXIO_ERR_IRQ | Error signaling from complex I/O: This interrupt is triggered when any error is received from the complex I/O (events are defined in CSI2_COMPLEXIO_IRQSTATUS [see Table 8-8]). |
| CSI2_IRQENABLE[8] FIFO_OVF_IRQ | FIFO overflow error: This interrupt is triggered when a FIFO overflow is detected. An overflow can occur if there is a mismatch between the data input and output rates. A reset of the module is required to restart correctly. |
| CSI2_IRQENABLE[7] CONTEXT7 | At least one interrupt event enabled from Context 7 occurred (see Table 8-9). |
| CSI2_IRQENABLE[6] CONTEXT6 | At least one interrupt event enabled from Context 6 occurred (see Table 8-9). |
| CSI2_IRQENABLE[5] CONTEXT5 | At least one interrupt event enabled from Context 5 occurred (see Table 8-9). |
| CSI2_IRQENABLE[4] CONTEXT4 | At least one interrupt event enabled from Context 4 occurred (see Table 8-9). |
| CSI2_IRQENABLE[3] CONTEXT3 | At least one interrupt event enabled from Context 3 occurred (see Table 8-9). |
| CSI2_IRQENABLE[2] CONTEXT2 | At least one interrupt event enabled from Context 2 occurred (see Table 8-9). |
| CSI2_IRQENABLE[1] CONTEXT1 | At least one interrupt event enabled from Context 1 occurred (see Table 8-9). |
| CSI2_IRQENABLE[0] CONTEXT0 | At least one interrupt event enabled from Context 0 occurred (see Table 8-9). |

Table 8-8 lists CSI2 receiver event generation through the CSI2-A/CSI2-B complex I/O interrupt status and interrupt enable registers. The events are checked and controlled from the CSI2_COMPLEXIO_IRQSTATUS and CSI2_COMPLEXIO_IRQENABLE registers.

Table 8-8. ISS CSI2-A and CSI2-B Receivers Complex I/O Interrupts

| Event and Register | Description |
|-------------------------------------------|---------------------------------------------|
| CSI2_COMPLEXIO_IRQENABLE[0] ERRSOTHS1 | Start of transmission error for lane 1 |
| CSI2_COMPLEXIO_IRQENABLE[1] ERRSOTHS2 | Start of transmission error for lane 2 |
| CSI2_COMPLEXIO_IRQENABLE[2] ERRSOTHS3 | Start of transmission error for lane 3 |
| CSI2_COMPLEXIO_IRQENABLE[5] ERRSOTSYNCHS1 | Start of transmission sync error for lane 1 |
| CSI2_COMPLEXIO_IRQENABLE[6] ERRSOTSYNCHS2 | Start of transmission sync error for lane 2 |
| CSI2_COMPLEXIO_IRQENABLE[7] ERRSOTSYNCHS3 | Start of transmission sync error for lane 3 |
| CSI2_COMPLEXIO_IRQENABLE[10] ERRESC1 | Escape entry error for lane 1 |
| CSI2_COMPLEXIO_IRQENABLE[11] ERRESC2 | Escape entry error for lane 2 |
| CSI2_COMPLEXIO_IRQENABLE[12] ERRESC3 | Escape entry error for lane 3 |
| CSI2_COMPLEXIO_IRQENABLE[15] ERRCONTROL1 | Control error for lane 1 |
| CSI2_COMPLEXIO_IRQENABLE[16] ERRCONTROL2 | Control error for lane 2 |
| CSI2_COMPLEXIO_IRQENABLE[17] ERRCONTROL3 | Control error for lane 3 |

Table 8-8. ISS CSI2-A and CSI2-B Receivers Complex I/O Interrupts (continued)

| Event and Register | Description |
|--------------------------------------------------|-------------------------------------------|
| CSI2_COMPLEXIO_IRQENABLE[20] STATEULPM1 | Lane 1 in ULPM |
| CSI2_COMPLEXIO_IRQENABLE[21] STATEULPM2 | Lane 2 in ULPM |
| CSI2_COMPLEXIO_IRQENABLE[22] STATEULPM3 | Lane 3 in ULPM |
| CSI2_COMPLEXIO_IRQENABLE[25] STATEALLULPMENTS | All active lanes are entering the ULPM. |
| CSI2_COMPLEXIO_IRQENABLE[26] STATEALLULPMEXIT | At least one active lane exited the ULPM. |

Because the CSI2-A/CSI2-B receivers support eight contexts, the CSI2_CTX_IRQSTATUS_i and CSI2_CTX_IRQENABLE_i registers are present eight times (one time per context).

The events are generated only for the enabled context(s). [Table 8-9](#) describes the generation of the CSI2 receiver event through the CSI2_CTX_IRQSTATUS_i and CSI2_CTX_IRQENABLE_i registers.

Table 8-9. ISS CSI2-A/CSI2-B Receivers CONTEXT Interrupts

| Event ⁽¹⁾ | Description |
|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CSI2_CTX_IRQENABLE_i[0] FS_IRQ | Frame start: This interrupt is triggered when a frame-start synchronization code is detected in the CSI2 data stream. |
| CSI2_CTX_IRQENABLE_i[1] FE_IRQ | Frame end: This interrupt is triggered when a frame-end synchronization code is detected in the CSI2 data stream. |
| CSI2_CTX_IRQENABLE_i[2] LS_IRQ | Line start: This interrupt is triggered when a line-start synchronization code is detected in the CSI2 data stream. |
| CSI2_CTX_IRQENABLE_i[3] LE_IRQ | Line end: This interrupt is triggered when a line-end synchronization code is detected in the CSI2 data stream. |
| CSI2_CTX_IRQENABLE_i[5] CS_IRQ | CS error: This interrupt is triggered when a mismatch between the transmitter and receiver checksums (payload) is detected. |
| CSI2_CTX_IRQENABLE_i[6] FRAME_NUMBER_IRQ | Frame counter reached: This interrupt is triggered when the frame counter reaches its programmable target value. |
| CSI2_CTX_IRQENABLE_i[7] LINE_NUMBER_IRQ | Line number reached: The programmable line number is received. The modulo feature can be selected (CSI2_CTX_CTRL1_i.LINE_MODULO). When selected, the interrupt is generated for each line number multiple of the programmed line number (CSI2_CTX_CTRL3_i.LINE_NUMBER); otherwise, the interrupt is generated only for the line number. |
| CSI2_CTX_IRQENABLE_i[8] ECC_CORRECTION_IRQ | ECC was used to correct a 1-bit error (long packets only). |

⁽¹⁾ i = 0 to 7

8.1.2.1.2.3 ISS CCP2 Interrupts

[Table 8-10](#) summarizes the CCP2 receiver interrupts.

Table 8-10. ISS CCP2 Receiver Interrupts

| Event and Register | Description |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CCP2_LC01_IRQENABLE[31] LC1_OCPERROR_IRQ | CCP2 write master interface port error on logical channel 1 |
| CCP2_LC01_IRQENABLE[27] LC1_FS_IRQ | CCP2 frame-start synchronization code detection on logical channel 1. This interrupt is triggered when a frame-start synchronization code is detected in the CCP2 data stream. |
| CCP2_LC01_IRQENABLE[26] LC1_LE_IRQ | CCP2 line-end synchronization code detection on logical channel 1. This interrupt is triggered when a line-end synchronization code is detected in the CCP2 data stream. |
| CCP2_LC01_IRQENABLE[25] LC1_LS_IRQ | CCP2 line-start synchronization code detection on logical channel 1. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream. |
| CCP2_LC01_IRQENABLE[24] LC1_FE_IRQ | CCP2 frame-end synchronization code detection on logical channel 1. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream. |

Table 8-10. ISS CCP2 Receiver Interrupts (continued)

| Event and Register | Description |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CCP2_LC01_IRQENABLE[23] LC1_COUNT_IRQ | CCP2 frame counter reached on logical channel 1. This interrupt is triggered when the frame counter reaches its programmable target value. |
| CCP2_LC01_IRQENABLE[21] LC1_FIFO_OVF_IRQ | CCP2 FIFO overflow error for logical channel 1. An overflow can occur if there is a mismatch between the data input and output rates. |
| CCP2_LC01_IRQENABLE[20] LC1_CRC_IRQ | CCP2 CRC error for logical channel 1. This interrupt is triggered when a mismatch between the transmitter and receiver checksums is detected. |
| CCP2_LC01_IRQENABLE[19] LC1_FSP_IRQ | CCP2 false-synchronization protection code error for logical channel 1. This interrupt is triggered by the FSP decoder if an illegal combination is detected, but 0xA5 is not present in the bitstream. |
| CCP2_LC01_IRQENABLE[18] LC1_FW_IRQ | CCP2 frame-width error for logical channel 1. This interrupt is generated if the frame width constraints associated with the current data type are not respected. |
| CCP2_LC01_IRQENABLE[17] LC1_FSC_IRQ | CCP2 false-synchronization code error for logical channel 1. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver finite state-machine (FSM). |
| CCP2_LC01_IRQENABLE[15] LC0_OCPERROR_IRQ | CCP2 write master interface port error on logical channel 1 |
| CCP2_LC01_IRQENABLE[11] LC0_FS_IRQ | CCP2 frame-start synchronization code detection on logical channel 0. This interrupt is triggered when a frame-start synchronization code is detected in the CCP2 data stream. |
| CCP2_LC01_IRQENABLE[10] LC0_LE_IRQ | CCP2 line-end synchronization code detection on logical channel 0. This interrupt is triggered when a line-end synchronization code is detected in the CCP2 data stream. |
| CCP2_LC01_IRQENABLE[9] LC0_LS_IRQ | CCP2 line-start synchronization code detection on logical channel 0. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream. |
| CCP2_LC01_IRQENABLE[8] LC0_FE_IRQ | CCP2 frame-end synchronization code detection on logical channel 0. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream. |
| CCP2_LC01_IRQENABLE[7] LC0_COUNT_IRQ | CCP2 frame counter reached on logical channel 0. This interrupt is triggered when the frame counter reaches its programmable target value. |
| CCP2_LC01_IRQENABLE[5] LC0_FIFO_OVF_IRQ | CCP2 FIFO overflow error for logical channel 0. An overflow can occur if there is a mismatch between the data input and output rates. |
| CCP2_LC01_IRQENABLE[4] LC0_CRC_IRQ | CCP2 CRC error for logical channel 0. This interrupt is triggered when a mismatch between the transmitter and receiver checksums is detected. |
| CCP2_LC01_IRQENABLE[3] LC0_FSP_IRQ | CCP2 false-synchronization code error for logical channel 0. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM. |
| CCP2_LC01_IRQENABLE[2] LC0_FW_IRQ | CCP2 frame-width error for logical channel 0. This interrupt is generated if the frame-width constraints associated with the current data type are not respected. |
| CCP2_LC01_IRQENABLE[1] LC0_FSC_IRQ | CCP2 false-synchronization code error for logical channel 0. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM. |
| CCP2_LC23_IRQENABLE[31] LC3_OCPERROR_IRQ | CCP2 write master interface port error on logical channel 3 |
| CCP2_LC23_IRQENABLE[27] LC3_FS_IRQ | CCP2 frame-start synchronization code detection on logical channel 3. This interrupt is triggered when a frame-start synchronization code is detected in the CCP2 data stream. |
| CCP2_LC23_IRQENABLE[26] LC3_LE_IRQ | CCP2 line-end synchronization code detection on logical channel 3. This interrupt is triggered when a line-end synchronization code is detected in the CCP2 data stream. |
| CCP2_LC23_IRQENABLE[25] LC3_LS_IRQ | CCP2 line-start synchronization code detection on logical channel 3. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream. |
| CCP2_LC23_IRQENABLE[24] LC3_FE_IRQ | CCP2 frame-end synchronization code detection on logical channel 3. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream. |
| CCP2_LC23_IRQENABLE[23] LC3_COUNT_IRQ | CCP2 frame counter reached on logical channel 3. This interrupt is triggered when the frame counter reaches its programmable target value. |

Table 8-10. ISS CCP2 Receiver Interrupts (continued)

| Event and Register | Description |
|------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CCP2_LC23_IRQENABLE[21] LC3_FIFO_OVF_IRQ | CCP2 FIFO overflow error for logical channel 3. An overflow can occur if there is a mismatch between the data input and output rates. |
| CCP2_LC23_IRQENABLE[20] LC3_CRC_IRQ | CCP2 CRC error for logical channel 3. This interrupt is triggered when a mismatch between the transmitter and receiver checksums is detected. |
| CCP2_LC23_IRQENABLE[19] LC3_FSP_IRQ | CCP2 false-synchronization code error for logical channel 3. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM. |
| CCP2_LC23_IRQENABLE[18] LC3_FW_IRQ | CCP2 frame-width error for logical channel 3. This interrupt is generated if the frame-width constraints associated with the current data type are not respected. |
| CCP2_LC23_IRQENABLE[17] LC3_FSC_IRQ | CCP2 false-synchronization code error for logical channel 3. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM. |
| CCP2_LC23_IRQENABLE[11] LC2_FS_IRQ | CCP2 frame-start synchronization code detection on logical channel 2. This interrupt is triggered on the detection of a frame-start synchronization code into the CCP2 data stream. |
| CCP2_LC23_IRQENABLE[10] LC2_LE_IRQ | CCP2 line-end synchronization code detection on logical channel 2. This interrupt is triggered on the detection of a line-end synchronization code into the CCP2 data stream. |
| CCP2_LC23_IRQENABLE[9] LC2_LS_IRQ | CCP2 line-start synchronization code detection on logical channel 2. This interrupt is triggered when a line-start synchronization code is detected in the CCP2 data stream. |
| CCP2_LC23_IRQENABLE[8] LC2_FE_IRQ | CCP2 frame-end synchronization code detection on logical channel 2. This interrupt is triggered when a frame-end synchronization code is detected in the CCP2 data stream. |
| CCP2_LC23_IRQENABLE[7] LC2_COUNT_IRQ | CCP2 frame counter reached on logical channel 2. This interrupt is triggered when the frame counter reaches its programmable target value. |
| CCP2_LC23_IRQENABLE[5] LC2_FIFO_OVF_IRQ | CCP2 FIFO overflow error for logical channel 2. An overflow can occur if there is a mismatch between the data input and output rates. |
| CCP2_LC23_IRQENABLE[4] LC2_CRC_IRQ | CCP2 CRC error for logical channel 2. This interrupt is triggered when a mismatch is detected between the transmitter and receiver checksums. |
| CCP2_LC23_IRQENABLE[3] LC2_FSP_IRQ | CCP2 false-synchronization code error for logical channel 2. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM. |
| CCP2_LC23_IRQENABLE[2] LC2_FW_IRQ | CCP2 frame-width error for logical channel 2. This interrupt is generated if the frame-width constraints associated with the current data type are not respected. |
| CCP2_LC23_IRQENABLE[1] LC2_FSC_IRQ | CCP2 false-synchronization code error for logical channel 2. This interrupt is triggered if the synchronization code order is not respected. This state is shown in the CCP2 receiver FSM. |
| CCP2_LCM_IRQENABLE[1] LCM_OCPERROR | CCP2 an interface error occurred on the master read port. This interrupt is triggered when an OCP error is detected on the master read port. |
| CCP2_LCM_IRQENABLE[0] LCM_EOF | Memory read channel – end of frame: This interrupt is triggered when a frame is read completely from memory. |

8.1.2.1.2.4 ISS CBUFF Interrupts

Table 8-11 summarizes the CBUFF interrupts.

Table 8-11. ISS CBUFF Interrupts

| Event and Register | Description |
|-----------------------------------------|----------------|
| CBUFF_HL_IRQENABLE_SET[31] IRQ_CTX7_OVR | CBUFF overflow |
| CBUFF_HL_IRQENABLE_SET[30] IRQ_CTX6_OVR | CBUFF overflow |
| CBUFF_HL_IRQENABLE_SET[29] IRQ_CTX5_OVR | CBUFF overflow |
| CBUFF_HL_IRQENABLE_SET[28] IRQ_CTX4_OVR | CBUFF overflow |
| CBUFF_HL_IRQENABLE_SET[27] IRQ_CTX3_OVR | CBUFF overflow |

Table 8-11. ISS CBUFF Interrupts (continued)

| Event and Register | Description |
|---------------------------------------------|------------------------------------------------------|
| CBUFF_HL_IRQENABLE_SET[26] IRQ_CTX2_OVR | CBUFF overflow |
| CBUFF_HL_IRQENABLE_SET[25] IRQ_CTX1_OVR | CBUFF overflow |
| CBUFF_HL_IRQENABLE_SET[24] IRQ_CTX0_OVR | CBUFF overflow |
| CBUFF_HL_IRQENABLE_SET[23] IRQ_CTX7_INVALID | CBUFF invalid access |
| CBUFF_HL_IRQENABLE_SET[22] IRQ_CTX6_INVALID | CBUFF invalid access |
| CBUFF_HL_IRQENABLE_SET[21] IRQ_CTX5_INVALID | CBUFF invalid access |
| CBUFF_HL_IRQENABLE_SET[20] IRQ_CTX4_INVALID | CBUFF invalid access |
| CBUFF_HL_IRQENABLE_SET[19] IRQ_CTX3_INVALID | CBUFF invalid access |
| CBUFF_HL_IRQENABLE_SET[18] IRQ_CTX2_INVALID | CBUFF invalid access |
| CBUFF_HL_IRQENABLE_SET[17] IRQ_CTX1_INVALID | CBUFF invalid access |
| CBUFF_HL_IRQENABLE_SET[16] IRQ_CTX0_INVALID | CBUFF invalid access |
| CBUFF_HL_IRQENABLE_SET[15] IRQ_CTX7_READY | CBUFF WB physical window ready for access by the CPU |
| CBUFF_HL_IRQENABLE_SET[14] IRQ_CTX6_READY | CBUFF WB physical window ready for access by the CPU |
| CBUFF_HL_IRQENABLE_SET[13] IRQ_CTX5_READY | CBUFF WB physical window ready for access by the CPU |
| CBUFF_HL_IRQENABLE_SET[12] IRQ_CTX4_READY | CBUFF WB physical window ready for access by the CPU |
| CBUFF_HL_IRQENABLE_SET[11] IRQ_CTX3_READY | CBUFF WB physical window ready for access by the CPU |
| CBUFF_HL_IRQENABLE_SET[10] IRQ_CTX2_READY | CBUFF WB physical window ready for access by the CPU |
| CBUFF_HL_IRQENABLE_SET[9] IRQ_CTX1_READY | CBUFF WB physical window ready for access by the CPU |
| CBUFF_HL_IRQENABLE_SET[8] IRQ_CTX0_READY | CBUFF WB physical window ready for access by the CPU |
| CBUFF_HL_IRQENABLE_SET[0] IRQ_OCP_ERR | CBUFF master interface port error |

8.1.2.1.2.5 ISS BTE Interrupts

Table 8-12 summarizes the BTE interrupts.

Table 8-12. ISS BTE Interrupts

| Event and Register | Description |
|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BTE_HL_IRQENABLE_SET[31] IRQ_CTX7_ERR | Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 7 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[30] IRQ_CTX6_ERR | Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 6 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[29] IRQ_CTX5_ERR | Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 5 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[28] IRQ_CTX4_ERR | Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 4 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[27] IRQ_CTX3_ERR | Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 3 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |

Table 8-12. ISS BTE Interrupts (continued)

| Event and Register | Description |
|-------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BTE_HL_IRQENABLE_SET[26] IRQ_CTX2_ERR | Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 2 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[25] IRQ_CTX1_ERR | Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 1 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[24] IRQ_CTX0_ERR | Writes enable notification for read request before enough data is prefetched. Reads notify when a read request that requires translation on Context 0 is received, but not enough frame lines have been prefetched in the buffer. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[23] IRQ_CTX7_INVALID | Writes enable invalid access to Context 7. Reads notify when access to an unexpected location in Context 7 is requested, or the start context location access is valid, but the burst length exceeds the Context 7 end. See Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| BTE_HL_IRQENABLE_SET[22] IRQ_CTX6_INVALID | Writes enable invalid access to Context 6. Reads notify when access to an unexpected location in Context 6 is requested, or the start context location access is valid, but the burst length exceeds the Context 6 end. See Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| BTE_HL_IRQENABLE_SET[21] IRQ_CTX5_INVALID | Writes enable invalid access to Context 5. Reads notify when access to an unexpected location in Context 5 is requested, or the start context location access is valid, but the burst length exceeds the Context 5 end. See Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| BTE_HL_IRQENABLE_SET[20] IRQ_CTX4_INVALID | Writes enable invalid access to Context 4. Reads notify when access to an unexpected location in Context 4 is requested, or the start context location access is valid, but the burst length exceeds the Context 4 end. See Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| BTE_HL_IRQENABLE_SET[19] IRQ_CTX3_INVALID | Writes enable invalid access to Context 3. Reads notify when access to an unexpected location in Context 3 is requested, or the start context location access is valid, but the burst length exceeds the Context 3 end. See Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| BTE_HL_IRQENABLE_SET[18] IRQ_CTX2_INVALID | Writes enable invalid access to Context 2. Reads notify when access to an unexpected location in Context 2 is requested, or the start context location access is valid, but the burst length exceeds the Context 2 end. See Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| BTE_HL_IRQENABLE_SET[17] IRQ_CTX1_INVALID | Writes enable invalid access to Context 1. Reads notify when access to an unexpected location in Context 1 is requested, or the start context location access is valid, but the burst length exceeds the Context 1 end. See Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| BTE_HL_IRQENABLE_SET[16] IRQ_CTX0_INVALID | Writes enable invalid access to Context 0. Reads notify when access to an unexpected location in Context 0 is requested, or the start context location access is valid, but the burst length exceeds the Context 0 end. See Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| BTE_HL_IRQENABLE_SET[15] IRQ_CTX7_DONE | Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 7 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |

Table 8-12. ISS BTE Interrupts (continued)

| Event and Register | Description |
|----------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BTE_HL_IRQENABLE_SET[14] IRQ_CTX6_DONE | Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 6 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[13] IRQ_CTX5_DONE | Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 5 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[12] IRQ_CTX4_DONE | Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 4 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[11] IRQ_CTX3_DONE | Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 3 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[10] IRQ_CTX2_DONE | Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 2 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[9] IRQ_CTX1_DONE | Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 1 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[8] IRQ_CTX0_DONE | Writes enable notification for context that has been fully and successfully transferred to TILER. Reads notify when enough frame lines have been prefetched into the buffer and Context 0 is translated to TILER. This interrupt is triggered when flushing completes (if enabled) in one-shot mode. It is triggered once per frame in continuous mode. See Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |
| BTE_HL_IRQENABLE_SET[1] IRQ_INVALID | Writes enable Invalid virtual space access notification. Reads notify when access falls into a translated from the BTE region, but it is 2D access or it does not map to an active context. See Section 8.2.7.3.2.4.3, ISS BTE Virtual Address Space and Context Mapping . |
| BTE_HL_IRQENABLE_SET[1] IRQ_OCP_ERR | Writes enable notification for error on the master output interface. Reads notify when an error has occurred on the master output interface. |

8.1.2.1.2.6 ISS SIMCOP Interrupts

[Table 8-13](#) summarizes the SIMCOP high-level interrupts mapped to the outer boundaries of the SIMCOP. For more information about interrupts generated from inside the SIMCOP modules, see the SIMCOP section.

Table 8-13. ISS SIMCOP High-Level Interrupts

| Event and Register | Description |
|----------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SIMCOP_HL_IRQENABLE_SET_i[19] CPU_PROC_START_IRQ | Interrupt used when CPU data processing is used in a macroblock processing pipeline. When the CPU receives this IRQ, data is ready to be processed. When the CPU finishes processing the data, it acknowledges by setting the SIMCOP_HWSEQ_CTRL.CPU_PROC_DONE bit. |
| SIMCOP_HL_IRQENABLE_SET_i[18] SIMCOP_DMA_IRQ1 | Interrupt triggered by SIMCOP DMA |
| SIMCOP_HL_IRQENABLE_SET_i[16] OCP_ERR_IRQ | SIMCOP master port interface error |
| SIMCOP_HL_IRQENABLE_SET_i[15] VLCDJ_DECODE_ERR_IRQ | A decode error has been signaled by the VLCDJ module. |
| SIMCOP_HL_IRQENABLE_SET_i[14] DONE_IRQ | Event triggered when hardware sequencer finishes the sequence: <ul style="list-style-type: none"> The sequence step counter has reached the limit. All accelerator and DMA events for the last sequence step have been received. |
| SIMCOP_HL_IRQENABLE_SET_i[13] STEP3_IRQ | Event triggered when a SIMCOP Context 3 is activated by the hardware sequencer. |
| SIMCOP_HL_IRQENABLE_SET_i[12] STEP2_IRQ | Event triggered when a SIMCOP Context 2 is activated by the hardware sequencer. |
| SIMCOP_HL_IRQENABLE_SET_i[11] STEP1_IRQ | Event triggered when a SIMCOP Context 1 is activated by the hardware sequencer. |
| SIMCOP_HL_IRQENABLE_SET_i[10] STEP0_IRQ | Event triggered when a SIMCOP Context 0 is activated by the hardware sequencer. |
| SIMCOP_HL_IRQENABLE_SET_i[9] LDC_BLOCK_IRQ | A macroblock has been processed. |
| SIMCOP_HL_IRQENABLE_SET_i[7] ROT_A | Rotational engine interrupt |
| SIMCOP_HL_IRQENABLE_SET_i[6] IMX_B_IRQ | Event triggered when iMX has executed a SLEEP instruction |
| SIMCOP_HL_IRQENABLE_SET_i[5] IMX_A_IRQ | Event triggered when iMX has executed a SLEEP instruction |
| SIMCOP_HL_IRQENABLE_SET_i[4] NSF_IRQ | Event triggered by the NSD2 imaging accelerator when processing of a block is done |
| SIMCOP_HL_IRQENABLE_SET_i[3] VLCDJ_BLOC_IRQ | A macroblock has been processed (that is, encode and decode). |
| SIMCOP_HL_IRQENABLE_SET_i[2] DCT_IRQ | DCT operating is complete (configured number of MCUs for YUV4:2:0/4:2:2 mode, or number of blocks for sequential block mode). |
| SIMCOP_HL_IRQENABLE_SET_i[1] LDC_FRAME_IRQ | A full frame has been processed. |
| SIMCOP_HL_IRQENABLE_SET_i[0] SIMCOP_DMA_IRQ0 | Interrupt triggered by SIMCOP DMA |

8.1.2.2 ISS Clocks

The clocks of ISS submodules can be cut individually using the [ISS_CLKCTRL](#) register. Software can poll the module status reading the appropriate bit in the [ISS_CLKSTAT](#) register.

When software wants to enable a submodule:

- Software sets the appropriate bit in the [ISS_CLKCTRL](#) register.
- Hardware enables the submodule functional and interface clocks (expected to take a few cycles).
- Hardware sets the appropriate bit in the [ISS_CLKSTAT](#) register.

Software must enable the modules in the correct order. The hardware imposes no particular constraint. For example, when data must be provided by the CSI2-A/CSI2-B receiver and processed by the ISP, both modules must be enabled and correctly configured before data arrives. An example of configuration order is: enabling the CSI2-A receiver powers up the complex I/O connected to the external sensor. Additionally, the ISP must be configured and the source interface must be selected. For details and the order of configuration, see the programming module of the particular submodule.

When software wants to shut down a submodule:

- Software ensures that the submodule is idle. Mainly:
 - The submodule must not generate new events.
 - The submodule must not have any pending events.

- For initiators: The submodule must stop the generation of an interface bridge transaction.
- Software clears the appropriate bit in the [ISS_CLKCTRL](#) register.
- For modules having only a master port: Hardware waits until the submodule to be disconnected asserts the MStandBy signal on its master port. It asserts MWait of the submodule.

NOTE: The ISS does not assert the MWait signal when a shutdown of the module is not requested by software.

- Hardware cuts the submodule clocks.
- Hardware clears the appropriate bit in the [ISS_CLKSTAT](#) register.

[Table 8-14](#) describes the clock gating of the ISS submodule.

Table 8-14. ISS Submodule Clock Gating

| ISS Resource | Feature On/Off Control |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ISS top-level resources | Not applicable. ISS top-level resources cannot be cut. However, top-level resources support the autogating feature. |
| SIMCOP | ISS_CLKCTRL[0] SIMCOP |
| ISP | ISS_CLKCTRL[1] ISP |
| CSI2-A | ISS_CLKCTRL[2] CSI2_A |
| CSI2-B | ISS_CLKCTRL[3] CSI2_B |
| CCP2 | ISS_CLKCTRL[4] CCP2 |
| ISS interconnect BTE CBUFF TCTRL | These modules cannot be switched off individually. They are required for any processing performed by SIMCOP because they are on the main data path. However, they support autogating to reduce power consumption when activity is low. |

When the clock of a submodule is cut and an interface bridge request for this module is received from the ISS configuration interconnect, the ISS clock manager temporarily enables the module clock to handle the access properly.

All ISS submodules are off after reset; software must enable them before they can be used.

8.1.2.3 ISS Reset

The ISS can accept a general software reset, propagated through all the hierarchy. This reset can be done to initialize the module and has the same effect as the hardware reset.

1. Set the [ISS_HL_SYSCONFIG\[0\]](#) SOFTRESET bit to 1.
2. Read the [ISS_HL_SYSCONFIG\[0\]](#) SOFTRESET bit to check whether it equals 0, which means the reset occurred.

If after five reads, [ISS_HL_SYSCONFIG\[0\]](#) SOFTRESET still returns 1, it can be assumed that an error occurred during the reset stage.

A software reset must not reset the power manager protocols (must not reset the IDLE and STANDBY generic IPs).

8.1.2.4 ISS Power Management

8.1.2.4.1 ISS Power-Management Infrastructure Overview

Figure 8-4 is an overview of the ISS power management.

Figure 8-4. ISS Power Management

camss-361

NOTE: For power savings, the PRCM module can request idle mode from the ISS. When the ISS is not functional, software must decide when the PRCM module can send the request. For more information, see [Section 3.1.1.1.2, Module Level Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

8.1.2.4.2 ISS STANDBY Mechanism

The power manager receives STANDBY information from the CCP2, CSI2-A, CSI2-B, ISP, and SIMCOP modules. These modules assert a standby signal when they have no more transactions to perform. The ISS power manager acknowledges by asserting a wait signal.

When those five modules are in standby mode, the ISS power manager initiates a STANDBY sequence for the ISS:

1. The ISS waits while the CCP2, CSI2-A, CSI2-B, ISP, and SIMCOP MStandby is asserted.
2. The ISS power manager acknowledges by asserting the CCP2, CSI2-A, CSI2-B, ISP, and SIMCOP MWait signal.
3. The ISS initiators assert only the MStandBy signal when they receive responses to all sent requests.

Therefore, when all initiators have asserted MStandBy, the ISS interconnect has no more pending traffic (although configurable, only nonposted writes must be used for error reporting).

4. The ISS power manager sends an IDLE request to the BTE. This IDLE request is used to drain BTE data. It does not affect the configuration port.
5. The BTE drains all transactions.
6. The BTE acknowledges the IDLE request.
7. The ISS power manager sends an IDLE request to the CBUFF. This IDLE request is used to drain CBUFF data. It does not affect the configuration port.
8. CBUFF drains all transactions.
9. CBUFF disconnects the interface master port connected to the L3 interconnect.
10. CBUFF acknowledges the IDLE request.
11. The ISS power manager asserts the MStandBy signals connected to the system PRCM module.
12. The PRCM module acknowledges by asserting the MWait signal.

A functional standby transition can be aborted when one of the CCP2, CSI2-A, CSI2-B, ISP, or SIMCOP modules deasserts the MStandBy signal. The corresponding MWait signal is deasserted only when the ISS interconnect, BTE, CBUFF, and ISS interface master port are ready to receive requests.

When one of the CCP2, CSI2-A, CSI2-B, ISP, or SIMCOP modules must perform accesses to the ISS interface master port, it deasserts the MStandBy signal. The ISS power manager executes the following sequence to leave the STANDBY state:

1. The ISS power manager deasserts the MStandby signal.
2. The ISS waits until the PRCM module deasserts the MWait signal.
3. The ISS power manager requests CBUFF to go into functional mode.
4. CBUFF connects the interface port.
5. The ISS power manager requests the BTE to go into functional mode.
6. The ISS power manager waits until CBUFF and BTE acknowledge functional mode.
7. The ISS deasserts the MWait signal of the module requesting access.

Abort of the standby-to-functional mode transition is not supported. The ISS power manager completes the standby-to-functional transition and then allows a new functional-to-standby transition.

Typically, the MStandby signal is used for two purposes. Software chooses one of the following behaviors through PRCM configuration:

- During blanking periods: The ISS asserts the MStandBy signal between frames when it has no more data to send. The PRCM module can use this information to switch off the L3 interconnect and save some dynamic power. However, the PRCM module is not allowed to cut the ISS functional clock in that case, because it is needed to receive the next frame.
- For ISS shutdown: The ISS asserts MStandBy when it has no more transactions to perform. The PRCM module then initiates an IDLE sequence. Once the ISS acknowledges the transition into idle mode, the PRCM module can cut the ISS clock and power.

The internal standby mode can be reached only when CCP2, CSI2-A, CSI2-B, SIMCOP, ISP, ISS data interconnect, BTE, and CBUFF are in IDLE or STANDBY state. Choosing no-idle or no-standby mode for any of these modules prevents the ISS from going into STANDBY state.

Four modes for standby control are supported, configured through the [ISS_HL_SYSCONFIG](#)[5:4] STANDBYMODE bit field:

- Smart-standby-wakeup mode: This is the mode normally used. When in this mode, the ISS asserts the MStandBy signal when the MStandBy of all ISS internal initiators is asserted and the ISS data interconnect, BTE, and CBUFF are in IDLE state.
- Smart-standby mode: The ISS has no wake-up event. This mode is equivalent to smart-standby-wakeup mode.
- Force-standby mode: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS asserts MStandBy unconditionally. Software must ensure that the ISS is in a correct quiet state before programming this mode.

- No-standby mode: This is a backup mode intended to be used only if smart-standby mode is bugged. When in this mode, the ISS never asserts the MStandBy signal.

8.1.2.4.3 ISS IDLE Mechanism

The PRCM module can request the ISS to go into IDLE state when the ISS has asserted its MStandBy output.

In a normal case, software must ensure that the ISS is in a quiet state before allowing the PRCM module to send an IDLE request to the ISS:

- The ISS has no more traffic to generate.
- The ISS cannot generate any new interrupts.
- The ISS has no pending interrupts.

When an IDLE request is received from the PRCM module, the ISS power manager verifies that the ISS MWait input has been asserted and that all ISS interrupt outputs are deasserted. It then starts the STANDBY-to-IDLE transition:

1. Send IDLE request to the ISS configuration interconnect.
2. The ISS configuration interconnect requests disconnection of both ISS interface slave ports. Disconnection is done by the master:
 - It stops accepting new requests and drains currently ongoing ones.
 - It waits for completion of all ongoing transactions.
3. The ISS configuration interconnect acknowledges the IDLE transition.
4. The ISS power manager acknowledges the IDLE request from the PRCM module.
5. The PRCM module can cut the ISS clock and power.

The PRCM module first enables the ISS power and clock before requesting the ISS to go into functional state by deasserting the SIdleReq signal. The ISS power manager then executes the wake-up sequence:

1. Request the ISS interconnect to go into functional state.
2. The ISS interconnect connects the ISS slave ports.
3. The ISS interconnect acknowledges transition into functional mode.
4. The ISS power manager acknowledges transition into functional mode (ISS output SIdleAck = 00).

Four modes for IDLE control are supported, controlled through the [ISS_HL_SYSCONFIG\[3:2\]](#) IDLEMODE bit field:

- Smart-idle-wakeup mode [b11]: This is the mode normally used. When in this mode, the ISS acknowledges a request to go idle from the power manager after having performed all hardware operations necessary for the IAF to be in a correct quiet state.
- Smart-idle mode [b10]: This is equivalent to smart-idle-wakeup mode.
- Force-idle mode [b00]: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, the ISS acknowledges a request to go idle from the power manager with no hardware condition. Software must ensure that the ISS is in a correct quiet state before requesting a force-idle transition.
- No-idle mode [b01]: When in this mode, the ISS disregards any request to go idle from the power manager.

8.1.3 ISS Register Manual

8.1.3.1 ISS Instance Summary

Table 8-15 is the ISS instance.

Table 8-15. ISS Instance Summary

| Module Name | Module Base Address | Size |

8.2 ISS Interfaces

8.2.1 ISS Interfaces Overview

Along with the submodules, the ISS has two camera interfaces: primary and secondary. The primary interface (CSI2-A) supports MIPI® CSI2 protocol with four data lanes, and the secondary interface (CSI2-B/CCP2) supports CSI2 protocol with one data lane or CCP2 protocol. All interfaces can use the image signal processor (ISP), but not concurrently. When one interface uses the ISP, the other must send data to memory. However, the ISP can still be used to process this data in memory-to-memory. Time multiplex processing is also possible.

[Figure 8-5](#) shows the ISS interfaces and interconnects.

Figure 8-5. ISS Interfaces and Interconnects Highlight

camss-006

8.2.1.1 ISS Interface Features

The camera subsystem supports the following features:

- System interfaces and interconnects:
 - Two 32-bit-wide configuration interfaces:
 - Interface to Cortex™-M3 microprocessor unit (MPU): Synchronous to the functional clock
 - Interface to Cortex™-A9 MPU and system direct memory access (sDMA): Asynchronous from

- the functional clock
- 128-bit-wide data interface to level 3 (L3) interconnect: Asynchronous from the functional clock
 - Shared interface level 2 (L2) in IVA-HD module for hardware encoding
 - Outside connection using the L3 interconnect through the TILER to the synchronous dynamic random access memory (SDRAM) controller (SDRC), which acts as the primary interface between the SDRAM and the ISS functional block
- The ISS has a local interconnect that connects all modules inside the ISS.
- BTE:
 - Tightly coupled with the TILER to support efficient rotation
- CBUFF:
 - Maps a linear space into a circular buffer
 - The buffer is physically located in system memory.
- TCTRL:
 - Control signal generation for flash prestrobe and strobe
 - Camera global reset control
- Camera interfaces:
 - Two CSI2 camera interfaces: CSI2-A (primary) and CSI2-B (secondary)
 - Transfer pixels and data received by the CSI2 digital physical layer receiver to the system memory or to the ISP
 - Use unidirectional data link
 - CSI2-A supports four configurable data links in addition to the clock signaling.
 - CSI2-B supports one configurable data link in addition to the clock signaling.
 - Maximum data rate of 1 Gbps per data lane
 - Data merger for 2-, 3-, or 4-data lane configuration
 - Maximum data rate of 1 Gbps per data lane, possible configurations are:
 - One data lane: 1000 Mbps (824 Mbps if lane 4 is used)
 - Two data lanes: 2 × 1000 Mbps (2 × 824 Mbps if lane 4 is used)
 - Three data lanes: 3 × 1000 Mbps (3 × 824 Mbps if lane 4 is used)
 - Four data lanes: 4 × 824 Mbps
 - Error detection and correction by the protocol engine
 - Direct memory access (DMA) engine integrated with dedicated first in first out (FIFO)
 - One-dimensional (1D) and two-dimensional (2D) addressing mode
 - Burst support
 - Streaming burst support (64- or 32-bit)
 - Eight contexts to support eight dedicated configurations of virtual channel ID and data types
 - Ping-pong mechanism for double-buffering
 - All primary and secondary MIPI-defined formats are supported.
 - Conversion of the RGB formats
 - On-the-fly differential pulse code modulation (DPCM) decompression
 - On-the-fly image cropping and A-law/DPCM compression
 - Configuration of the complex input/output (I/O) physical layer (PHY) (MIPI D-PHY-compliant receiver PHY solution [D-PHY mode]/CCP2-compatible receiver PHY solution (CCP2 mode)
 - CCP2 camera interface (secondary)
 - Four logical channels
 - Transfer pixels and data received by the complex I/O PHY (CCP2 D-PHY RX to the system memory or the ISP)
 - Use unidirectional data link

- Maximum data rate of 650 Mbps
- DMA engine integrated with dedicated FIFO
- 1D and 2D addressing mode
- False synchronization code protection
- Ping-pong mechanism for double-buffering
- RGB, RAW, YUV, and JPEG formats supported
- On-the-fly DPCM decompression
- On-the-fly image cropping and A-Law/DPCM compression
- System memory data read back port (supported by the CCP2 protocol engine)
 - RAW 6, 7, 8, 10, 12, 14, 16 formats supported
 - DPCM and A-law decompression
 - Supports image cropping for compressed or uncompressed data

NOTE: Rotated DPCM data is not supported.

8.2.2 ISS Interfaces Environment

8.2.2.1 ISS Interfaces Signal Descriptions

Table 8-37 summarizes the I/O signals.

Table 8-37. ISS I/O Description

Table 8-37. ISS I/O Description (continued)

| Signal Name | I/O ⁽¹⁾ | Description | Serial Mode CCP2 | Serial Mode CSI2 |
|-------------|--------------------|-------------------------------------------------------|------------------|------------------|
| ccp2_datp | I | Serial CCP2 mode: Differential data positive input | x | |
| ccp2_datn | I | Serial CCP2 mode: Differential data negative input | x | |

NOTE: Lane polarity can be changed in complex I/O. For more information, see [Section 8.2.2.2, ISS Interface Modes](#).

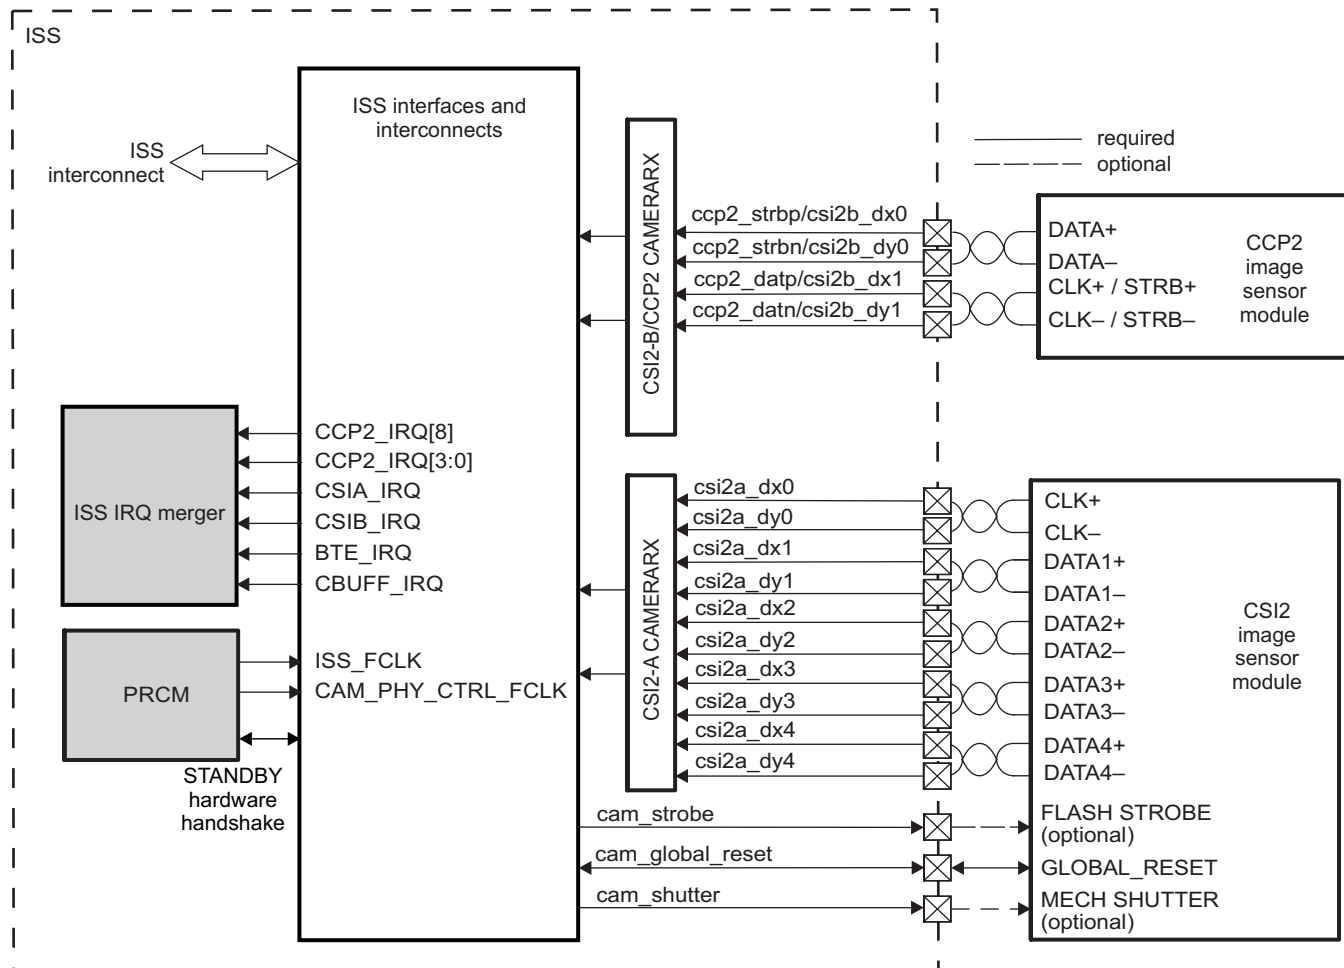

NOTE: At least one data lane must be configured for using the CSI2-A and CSI2-B interfaces. The signals are also configurable from the control module. Thus, they are not required to be at a certain location to act as clock or data; this can be configured.

NOTE: CCP2 and CSI2-B share pins. Their modes are not supported as a pin configuration mux option. The modes are configured from the CSI2-B/CCP2 CAMERARX configured from the system control module (see [Chapter 18, Control Module](#)).

8.2.2.2 ISS Interface Modes

The camera subsystem can manage up to two serial image sensors that can be active at the same time. However, only one data flow can use the ISP. [Figure 8-6](#) shows an example block diagram of the interface configuration. Each serial port clock lane is configurable. The MIPI CSI2 protocol requires only a clock lane setup. The data lane configuration is optional. For more information, see [Section 8.2.5.1.1](#).

Figure 8-6. ISS CSI2-A, CSI2-B/CCP2 Serial Interface Configuration

camss-005u

NOTE: Depending on the needs, `cam_strobe`, `cam_global_reset`, and `cam_shutter` can be connected to the image sensor module rather than the CSI2 image sensor module.

NOTE: Dedicated power, reset, and clock management (PRCM) module pins for power and ground are provided for external sensors: `vdda_csi2a`, `vdda_csi2b`, `vssa_csi2a`, and `vssa_csi2b`.

A graphical representation of the pins for connecting external sensors to the ISS shows a variety of connectivity configurations that are possible by setting the PHY immediately before the receivers, and a variety of output paths, including some sensor data through the receivers to memory or the ISP. [Table 8-38](#) lists some of the connectivity possibilities; the ISP can take only one input lane at a time. For more information about the operating properties and configuration of the CAMERARX PHY, see [Section 8.2.3, ISS CSI2 PHY](#).

Table 8-38. ISS Interfaces Connectivity Scheme Example Scenarios

⁽¹⁾ Full: All data/clock lanes are connected.

⁽²⁾ Limited: Some data/clock lanes are connected.

NOTE: The ISP can take only one input at a time. The other inputs must go to memory and then be processed after the ISP processes the input that was received first.

In looking at the sample connections between the ISS through the receivers and external sensors, it is apparent that the lanes of the input can be adjusted for certain needs. For example, it is not necessary that the CSI2-A has four data lanes connected at the same time. The only restriction is that CSI2-B is limited to one data lane. Because CSI2-B and CCP2 share pins, they cannot be used simultaneously. CSI2-A and CSI2-B/CCP2 can function at the same time by sending data to memory. In this manner, external sensors can be connected any way possible for best performance and results.

8.2.3 ISS CSI2 PHY

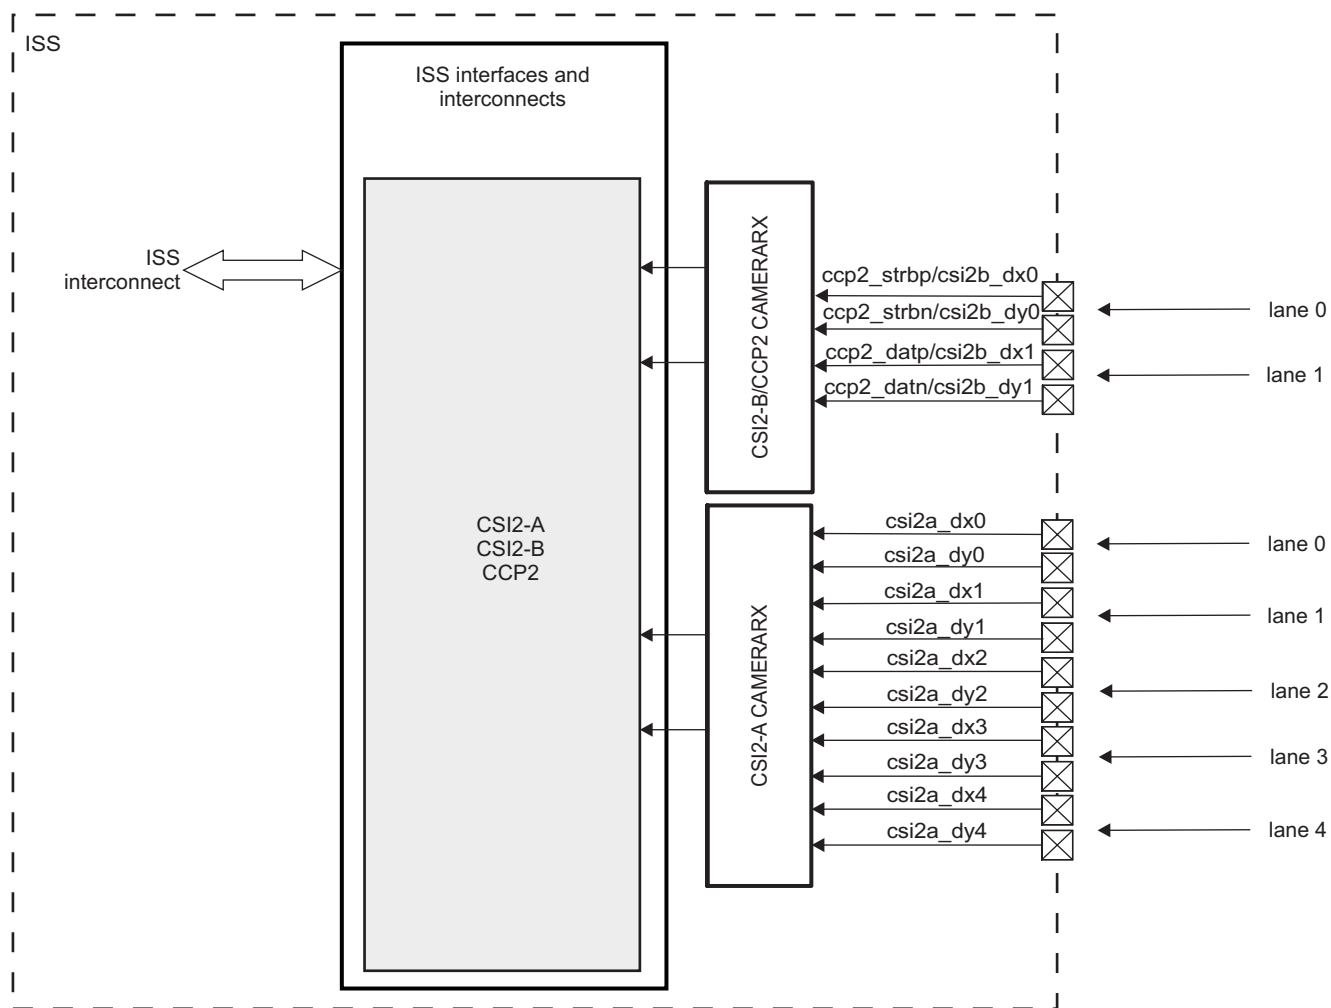

8.2.3.1 ISS CSI2 PHY Overview

Two MIPI D-PHY-compliant CAMERARX PHY receivers immediately before the ISS interfaces act as a physical connection and configuration of clock/data lanes with external sensors. CAMERARX PHY supports up to four configurations, depending on the required number of D-PHY data lane external sensors. The receivers are compatible with the *MIPI D-PHY Specification v0.92*. The selection of CAMERARX in D-PHY mode or CCP2 mode must be done before reset and not on the fly.

The PHY is controlled and must be configured first from the control module for pad configuration. The differential data/clock lanes coming into the CSI2-A and CSI2-B CAMERARX are configured from registers explained in [Section 18.4.8.4](#) (see register CONTROL_CAMERA_RX).

As mentioned previously, two PHYs are integrated in the device. The CSI2-A CAMERARX contains four data lanes, as shown in [Figure 8-7](#); CSI2-B is the same except that it has one data lane plus a clock/strobe lane. The figure also shows case CSI2-A, with four data lanes and one clock, listed in [Table 8-38](#).

Figure 8-7. ISS Interfaces CSI2-A PHY Diagram Four D-PHY Data Lane Configuration

camss-704b

NOTE: If CCP2 mode is chosen for use in the CSI2-B/CCP2 CAMERARX, then LANE 0 and LANE 1 are used only as datp/datn and strbp/strbn.

NOTE: Lane 4 can be used only as a data lane, never as a clock lane. All other configurations are possible. Also, a speed restriction is present when lane 4 is used; then all data lanes perform at up to 824 Mbps instead of 1000 Mbps.

CSI2-A and CSI2-B/CCP2 CAMERARX represent the overall PHY solution for connecting external sensors to feed the ISS. The MIPI D-PHY function can support up to four data lane modules and one clock lane module. Reverse direction escape mode is not supported. The lane module polarity and positions are configurable; that is, any lane module can be chosen as the clock lane module, and the DX/DY data pad for each lane module can be configured as DP or DN pins defined. The configuration and the selection of D-PHY mode, data/clock, or data/strobes are done through the control module (see [Chapter 18, Control Module](#)). The only exception is the four-data-lane use case, in which one corner lane is allowed to be only a data lane. For the CCP2 function, the CAMERARX PHY solution supports one data/strobe or data/clock lane module. The data lane module and strobe lane module must be physically adjacent. CAMERARX supports serial configuration protocol for the configuration interface.

8.2.3.2 ISS CSI2 PHY Functional Description

8.2.3.2.1 ISS CSI2 PHY Functional Configuration

The CSI2 PHY converts the bitstream, divided into 1 to 4 serial data lanes, into a bitstream compatible with the CSI2 receiver and one clock lane.

The [CSI2_COMPLEXIO_IRQSTATUS](#) register logs complex I/O events of the following types:

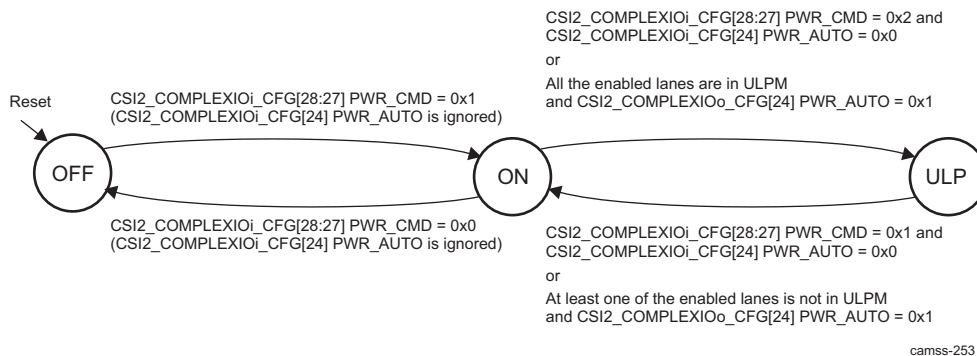

- Line power-state change (all lanes in ultralow-power mode [ULPM], at least one lane exits ULPM, etc.)
- Error on one lane

The CSI2 receiver embeds two registers to configure/read some complex I/O parameters:

- The [REGISTER0](#) register detects clock miss with respect to the *MIPI D-PHY Specification v0.92* and control timing.
- The [REGISTER1](#) register reports completion of reset on the different parts of the module and configures the timing parameters.
- The [CSI2_COMPLEXIO_CFG](#) registers contain the PWR_AUTO and PWR_CMD bit fields, which affect the power management of the two complex I/Os.

The complex I/O has three power modes: on, off, and ultralow power (ULP). These modes can reflect the ON or ULP states of the five differential lines if the [CSI2_COMPLEXIO_CFG\[24\]](#) PWR_AUTO bit is set to 1. If the PWR_AUTO bit is at reset value (0), the complex I/O power state is controlled by the [CSI2_COMPLEXIO_CFG\[28:27\]](#) PWR_CMD bit field, which directly defines the power state. [Figure 8-8](#) shows the complex I/O power finite state-machine (FSM).

Figure 8-8. ISS CSI2 Complex I/O Power FSM

Another register, [CSI2_TIMING](#), is used to control the power state of the complex I/O modules with regard to the differential line state. This register controls the mode of the two complex I/Os (RxMode and NoRxMode) and the delay between the differential lanes in STOP state and the complex I/O on NoRxMode. The [CSI2_TIMING\[15\]](#) FORCE_RX_MODE_IO1 bit sets the complex I/O in RxMode or NoRxMode (stopped mode). The FORCE_RX_MODE_IO1 bit is automatically reset to 0 by hardware when

the counter ends and the FSM returns to NoRxMode. Three bits ([CSI2_TIMING\[14\]](#) STOP_STATE_X16_IO1, [CSI2_TIMING\[13\]](#) STOP_STATE_X4_IO1, and the [CSI2_TIMING\[12:0\]](#) STOP_STATE_COUNTER_IO1 bit field) configure the delay between line stop mode and complex I/O stop mode. The delay represents the number of functional clock (ISS_FCLK) cycles and can be calculated as follows:

Total delay in ISS_FCLK cycle = [CSI2_TIMING.STOP_STATE_COUNTER_IO](#) x (1+[CSI2_TIMING.STOP_STATE_X16_IO](#) x 15) x (1+[CSI2_TIMING.STOP_STATE_X4_IO](#) x 3).

[Table 8-39](#) lists the possible values of the delay, in terms of the ISS_FCLK cycles, depending on the values of the STOP_STATE_X16_IO and STOP_STATE_X4_IO bits.

Table 8-39. ISS CSI2 Possible Time-Out Value for RxMode Counter

| STOP_STATE_X16_IO | STOP_STATE_X4_IO | Possible Delay Value (in Functional Clock Cycles) |
|-------------------|------------------|---------------------------------------------------|
| 0x0 | 0x0 | 8191 (with step of 1) |
| 0x0 | 0x1 | 32764 (with step of 4) |
| 0x1 | 0x0 | 131056 (with step of 16) |
| 0x1 | 0x1 | 524224 (with step of 64) |

The FORCERXMODE signal is used at initialization time (complex I/O). [Figure 8-9](#) describes the ForceRxMode and StopState FSM to assert and deassert the FORCERXMODE signal and to monitor STOPSTATE from the complex I/O.

Figure 8-9. ISS CSI2 RxMode and StopState FSM

8.2.3.2.2 ISS CSI2 PHY and Link Initialization Sequence

The MIPI D-PHY initialization sequence is not implemented within CAMERARX. The CSI2-A receiver is expected to coordinate the PHY initialization. The controller must ensure that the PHY is held in RESET/WAIT for RX mode until the D-PHY transmitter is powered up and the link comes to the defined state. The controller can use the STOPSTATE and FORCERXMODE signals of CAMERARX for this purpose. STOPSTATE indicates the line states, while FORCERXMODE forces the receiver state-machine into "wait for stop state." One possible initialization sequence is:

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI2 receiver registers to be ready to receive signals/data from the CSIPHY:
 - (a) Configure all needed CSI2 registers:
 - (i) Set [CSI2_COMPLEXIO_CFG\[18:16\]](#) DATA4_POSITION.
 - (ii) Set [CSI2_COMPLEXIO_CFG\[14:12\]](#) DATA3_POSITION.
 - (iii) Set [CSI2_COMPLEXIO_CFG\[10:8\]](#) DATA2_POSITION.
 - (iv) Set [CSI2_COMPLEXIO_CFG\[6:4\]](#) DATA1_POSITION.
 - (v) Set [CSI2_COMPLEXIO_CFG\[2:0\]](#) CLOCK_POSITION.
 - (vi) Set the [CONTROL_CAMERA_RX\[20:19\]](#) CAMERARX_CSI22_CAMMODE or [CONTROL_CAMERA_RX\[17:16\]](#) CAMERARX_CSI21_CAMMODE.

CAUTION

This must be done before the CSIPHY is active.

(vii) A dedicated internal clock gate control is present for each PHY. Enable or disable the internal CTRLCLK from the CAMERARX_CSI22_CTRLCLKE[21] CAMERARX_CSI22_CTRLCLKE bit or the [18] CAMERARX_CSI21_CTRLCLKE bit.

2. CSIPHY and link initialization sequence:

(a) Deassert the CSIPHY reset.

(i) Set [CSI2_COMPLEXIO_CFG\[30\]](#) RESET_CTRL to 0x1.

CAUTION

For the [CSI2_COMPLEXIO_CFG\[29\]](#) RESET_DONE bit to be set to 0x1 (reset completed), the external sensor must be active and sending the MIPI HS BYTECLK.

The following registers can be set only after deasserting the CSIPHY reset and before asserting the FORCERXMODE signal:

- [REGISTER0](#)
- [REGISTER1](#)
- [REGISTER2](#)

(b) Assert the FORCERXMODE signal:

(i) Set [CSI2_TIMING\[15\]](#) FORCE_RX_MODE_IO1 to 0x1.

(c) Connect pulldown on link (DP/DN) by asserting the respective PIPD* signals (PIPD* = 0):

For CSI2-A CAMERARX pulldown on signals through padconf registers:

- csi21_dx4:
 - CONTROL_CORE_PAD0_CSI21_DX4_PAD1_CSI21_DY4[8] CSI21_DX4_INPUTENABLE = 0x1
 - CONTROL_CORE_PAD0_CSI21_DX4_PAD1_CSI21_DY4[4] CSI21_DX4_PULLTYPESELECT = 0x0
 - CONTROL_CORE_PAD0_CSI21_DX4_PAD1_CSI21_DY4[3] CSI21_DX4_PULLUDENABLE = 0x1
- csi21_dy4:
 - CONTROL_CORE_PAD0_CSI21_DX4_PAD1_CSI21_DY4[24] CSI21_DY4_INPUTENABLE = 0x1
 - CONTROL_CORE_PAD0_CSI21_DX4_PAD1_CSI21_DY4[20] CSI21_DY4_PULLTYPESELECT = 0x0
 - CONTROL_CORE_PAD0_CSI21_DX4_PAD1_CSI21_DY4[19] CSI21_DY4_PULLUDENABLE = 0x1
- csi21_dx3:
 - CONTROL_CORE_PAD0_CSI21_DX3_PAD1_CSI21_DY3[8] CSI21_DX3_INPUTENABLE = 0x1
 - CONTROL_CORE_PAD0_CSI21_DX3_PAD1_CSI21_DY3[4] CSI21_DX3_PULLTYPESELECT = 0x0
 - CONTROL_CORE_PAD0_CSI21_DX3_PAD1_CSI21_DY3[3] CSI21_DX3_PULLUDENABLE = 0x1
- csi21_dy3:
 - CONTROL_CORE_PAD0_CSI21_DX3_PAD1_CSI21_DY3[24] CSI21_DY3_INPUTENABLE = 0x1

- CONTROL_CORE_PAD0_CSI21_DX3_PAD1_CSI21_DY3[20]
CSI21_DY3_PULLTYPESELECT= 0x0
- CONTROL_CORE_PAD0_CSI21_DX3_PAD1_CSI21_DY3[19]
CSI21_DY3_PULLUDENABLE = 0x1
- csi21_dx2:
 - CONTROL_CORE_PAD0_CSI21_DX2_PAD1_CSI21_DY2[8] CSI21_DX2_INPUTENABLE
= 0x1
 - CONTROL_CORE_PAD0_CSI21_DX2_PAD1_CSI21_DY2[4]
CSI21_DX2_PULLTYPESELECT= 0x0
 - CONTROL_CORE_PAD0_CSI21_DX2_PAD1_CSI21_DY2[3]
CSI21_DX2_PULLUDENABLE = 0x1
- csi21_dy2:
 - CONTROL_CORE_PAD0_CSI21_DX2_PAD1_CSI21_DY2[24] CSI21_DY2_INPUTENABLE
= 0x1
 - CONTROL_CORE_PAD0_CSI21_DX2_PAD1_CSI21_DY2[20]
CSI21_DY2_PULLTYPESELECT= 0x0
 - CONTROL_CORE_PAD0_CSI21_DX2_PAD1_CSI21_DY3[19]
CSI21_DY2_PULLUDENABLE = 0x1
- csi21_dx1:
 - CONTROL_CORE_PAD0_CSI21_DX1_PAD1_CSI21_DY1[8] CSI21_DX1_INPUTENABLE
= 0x1
 - CONTROL_CORE_PAD0_CSI21_DX1_PAD1_CSI21_DY1[4]
CSI21_DX1_PULLTYPESELECT= 0x0
 - CONTROL_CORE_PAD0_CSI21_DX1_PAD1_CSI21_DY1[3]
CSI21_DX1_PULLUDENABLE = 0x1
- csi21_dy1:
 - CONTROL_CORE_PAD0_CSI21_DX1_PAD1_CSI21_DY1[24] CSI21_DY1_INPUTENABLE
= 0x1
 - CONTROL_CORE_PAD0_CSI21_DX1_PAD1_CSI21_DY1[20]
CSI21_DY1_PULLTYPESELECT= 0x0
 - CONTROL_CORE_PAD0_CSI21_DX1_PAD1_CSI21_DY1[19]
CSI21_DY1_PULLUDENABLE = 0x1
- csi21_dx0:
 - CONTROL_CORE_PAD0_CSI21_DX0_PAD1_CSI21_DY0[8] CSI21_DX0_INPUTENABLE
= 0x1
 - CONTROL_CORE_PAD0_CSI21_DX0_PAD1_CSI21_DY0[4]
CSI21_DX0_PULLTYPESELECT= 0x0
 - CONTROL_CORE_PAD0_CSI21_DX0_PAD1_CSI21_DY0[3]
CSI21_DX0_PULLUDENABLE = 0x1
- csi21_dy0:
 - CONTROL_CORE_PAD0_CSI21_DX0_PAD1_CSI21_DY0[24] CSI21_DY0_INPUTENABLE
= 0x1
 - CONTROL_CORE_PAD0_CSI21_DX0_PAD1_CSI21_DY0[20]
CSI21_DY0_PULLTYPESELECT= 0x0
 - CONTROL_CORE_PAD0_CSI21_DX0_PAD1_CSI21_DY0[19]
CSI21_DY0_PULLUDENABLE = 0x1

For CSI2-B/CCP2 CAMERARX pulldown on signals through padconf registers:

- csi22_dx1:
 - CONTROL_CORE_PAD0_CSI22_DX1_PAD1_CSI22_DY1[8] CSI22_DX1_INPUTENABLE
= 0x1
 - CONTROL_CORE_PAD0_CSI22_DX1_PAD1_CSI22_DY1[4]

- CSI22_DX1_PULLTYPESELECT = 0x0
 - CONTROL_CORE_PAD0_CSI22_DX1_PAD1_CSI22_DY1[3]
CSI22_DX1_PULLUDENABLE = 0x1
 - csi22_dy1:
 - CONTROL_CORE_PAD0_CSI22_DX1_PAD1_CSI22_DY1[24] CSI22_DY1_INPUTENABLE = 0x1
 - CONTROL_CORE_PAD0_CSI22_DX1_PAD1_CSI22_DY1[20]
CSI22_DY1_PULLTYPESELECT = 0x0
 - CONTROL_CORE_PAD0_CSI22_DX1_PAD1_CSI22_DY1[19]
CSI22_DY1_PULLUDENABLE = 0x1
 - csi22_dx0:
 - CONTROL_CORE_PAD0_CSI22_DX0_PAD1_CSI22_DY0[8] CSI22_DX0_INPUTENABLE = 0x1
 - CONTROL_CORE_PAD0_CSI22_DX0_PAD1_CSI22_DY0[4]
CSI22_DX0_PULLTYPESELECT = 0x0
 - CONTROL_CORE_PAD0_CSI22_DX0_PAD1_CSI22_DY0[3]
CSI22_DX0_PULLUDENABLE = 0x1
 - csi22_dy0:
 - CONTROL_CORE_PAD0_CSI22_DX0_PAD1_CSI22_DY0[24] CSI22_DY0_INPUTENABLE = 0x1
 - CONTROL_CORE_PAD0_CSI22_DX0_PAD1_CSI22_DY0[20]
CSI22_DY0_PULLTYPESELECT = 0x0
 - CONTROL_CORE_PAD0_CSI22_DX0_PAD1_CSI22_DY0[19]
CSI22_DY0_PULLUDENABLE = 0x1
- (d) Power up the CSIPHY:
- (i) Set [CSI2_COMPLEXIO_CFG](#)[28:27] PWR_CMD to 0x1.
- (e) Check whether the state status reaches the ON state:
- [CSI2_COMPLEXIO_CFG](#)[26:25] PWR_STATUS = 0x1
- (f) Wait for STOPSTATE = 1 (for all enabled lane modules):
- (i) The timer is set through the [CSI2_TIMING](#)[14:0] bit field. The reset value can be kept.
 - (ii) Wait until [CSI2_TIMING](#)[15] FORCE_RX_MODE_IO1 = 0x0. It is automatically put at 0 when all enabled lanes are in STOPSTATE and the timer is finished.
- (g) Release PIPD* (= 1).
- For CSI2-A CAMERARX pullup on signals through padconf registers:
- csi21_dx4:
 - CONTROL_CORE_PAD0_CSI21_DX4_PAD1_CSI21_DY4[4]
CSI21_DX4_PULLTYPESELECT = 0x1
 - csi21_dy4:
 - CONTROL_CORE_PAD0_CSI21_DX4_PAD1_CSI21_DY4[20]
CSI21_DY4_PULLTYPESELECT = 0x1
 - csi21_dx3:
 - CONTROL_CORE_PAD0_CSI21_DX3_PAD1_CSI21_DY3[4]
CSI21_DX3_PULLTYPESELECT = 0x1
 - csi21_dy3:
 - CONTROL_CORE_PAD0_CSI21_DX3_PAD1_CSI21_DY3[20]
CSI21_DY3_PULLTYPESELECT = 0x1
 - csi21_dx2:
 - CONTROL_CORE_PAD0_CSI21_DX2_PAD1_CSI21_DY2[4]
CSI21_DX2_PULLTYPESELECT = 0x1

- csi21_dy2:
 - CONTROL_CORE_PAD0_CSI21_DX2_PAD1_CSI21_DY2[20]
CSI21_DY2_PULLTYPESELECT = 0x1
 - csi21_dx1:
 - CONTROL_CORE_PAD0_CSI21_DX1_PAD1_CSI21_DY1[4]
CSI21_DX1_PULLTYPESELECT = 0x1
 - csi21_dy1:
 - CONTROL_CORE_PAD0_CSI21_DX1_PAD1_CSI21_DY1[20]
CSI21_DY1_PULLTYPESELECT = 0x1
 - csi21_dx0:
 - CONTROL_CORE_PAD0_CSI21_DX0_PAD1_CSI21_DY0[4]
CSI21_DX0_PULLTYPESELECT = 0x1
 - csi21_dy0:
 - CONTROL_CORE_PAD0_CSI21_DX0_PAD1_CSI21_DY0[20]
CSI21_DY0_PULLTYPESELECT = 0x1
3. The CSIPHY is initialized and ready/active in CSI2 mode.

8.2.3.2.3 ISS CCP2 and Link Initialization Sequence

The CSI2-B interface is expected to coordinate the PHY initialization. The controller must ensure that the PHY is held in RESET state until the CCP transmitter is powered up and the link comes to the defined state. The controller can use the FORCERXMODE signals of CAMERARX for this purpose. FORCERXMODE forces the receiver state-machine into RESET state, while the rest of common logic is powered up and functional. One possible initialization sequence is:

To fully initialize the CSIPHY, perform the following steps:

1. Configure all CSI2-B receiver registers to be ready to receive signals/data from the CSIPHY:
 - (a) Configure all CCP2 registers:
 - (i) Set [CSI2_COMPLEXIO_CFG\[2:0\]](#) CLOCK_POSITION.
 - (ii) Set [CSI2_COMPLEXIO_CFG\[6:4\]](#) DATA1_POSITION.
 - (b) Set [CONTROL_CAMERA_RX\[20:19\]](#) CAMERARX_CSI22_CAMMODE.

CAUTION

This must be done before the CSIPHY is active.

- (c) A dedicated internal clock gate control is present for each PHY. Enable or disable the internal CTRLCLK from the [CAMERARX_CSI22_CTRLCLKE\[21\]](#) CAMERARX_CSI22_CTRLCLKE bit or the [18] CAMERARX_CSI21_CTRLCLKE bit.
2. CSIPHY and link initialization sequence:
 - (a) Deassert the CSIPHY reset:
 - (i) Set [CSI2_COMPLEXIO_CFG\[30\]](#) RESET_CTRL to 0x1.
 - (b) Assert the FORCERXMODE signal:
 - (i) Set [CSI2_TIMING\[15\]](#) FORCE_RX_MODE_IO1 to 0x1.
 - (c) Power up the CSIPHY:
 - (i) Set [CSI2_COMPLEXIO_CFG\[28:27\]](#) PWR_CMD to 0x1.
 - (d) Check that the state status reaches the ON state:
 - [CSI2_COMPLEXIO_CFG\[26:25\]](#) PWR_STATUS = 0x1
 - (e) Release the FORCERXMODE signal:
 - (i) Set [CSI2_TIMING\[15\]](#) FORCE_RX_MODE_IO1 to 0x0.

- The CSIPHY is initialized and ready/active in CSI1/CCP2B mode.

8.2.3.2.4 ISS CSI PHY Error Signals

In D-PHY mode, the CSIPHY supports the following error detection and signaling to the associated receiver:

- ERRSOTHS:** Flags 1-bit errors in the HS start of transmission synchronization pattern. In this error scenario, the CSIPHY continues to receive the data and pass it to the receiver, but confidence in the data may be low, because of the 1-bit error seen in sync. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRSOTSYNCHS:** Flags multiple bit errors in the HS start of transmission synchronization pattern. In this case, the CSIPHY cannot achieve proper synchronization and does not pass the received data to the receiver. This signal, if asserted, is high for one cycle of RXBYTECLKHS.
- ERRCONTROL:** Flags the control sequence error; that is, when the LP sequence observed on line is not recognized as a valid control sequence. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRESC:** Flags the escape entry error; that is, when the escape entry sequence is unrecognized. This signal, if asserted, is high until the next change in the state of the LP line.
- ERRSYNDESC:** Flags the low-power data transmission synchronization error. This error is flagged if the number of bits received during a low-power data transmission is not a multiple of 8 bits. This signal, if asserted, is high until the next change in the state of the LP line. In case the number of received bits is 1 less than a multiple of 8, RXVALIDESC is also asserted together with ERRSYNDESC, and an erroneous data byte is output on RXDATAESC. In other cases of this error, RXVALIDESC is not asserted and an erroneous data byte is not sent out.

In CCP2 mode, the CSIPHY supports the following error detection and signaling to the associated receiver:

- CCPPERRESYNC** output is an error indicator to the receiver to flag the shifted synchronization error, if the new synchronization sequence is not aligned with a 32-bit word boundary compared to the previously received synchronization sequence. This error flag is asserted for 32 cycles (4 bytes/32 bits).

8.2.3.3 ISS CSI2 PHY Register Manual

8.2.3.3.1 ISS CSI2 PHY Instance Summary

Table 8-40 lists the ISS CSI2 PHY instance.

Table 8-40. ISS CSI2 PHY Instance Summary

| Module Name | L3 Base Address | Size |
|--------------------|-----------------|----------|
| ISS_CAMERARX_CORE1 | 0x5200 1170 | 32 bytes |
| ISS_CAMERARX_CORE2 | 0x5200 1570 | 32 bytes |

NOTE: ISS_CAMERARX_CORE1 is for CSI2-A CAMERARX.

ISS_CAMERARX_CORE2 is for CSI2-B/CCP2 CAMERARX.

8.2.3.3.2 ISS CSI2 PHY Registers

8.2.3.3.2.1 ISS CSI2 PHY Register Summary

Table 8-41 summarizes the ISS CSI2 register mapping.

Table 8-41. ISS CSI2 PHY Registers Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | ISS_CAMERARX_CORE1 Base Address | ISS_CAMERARX_CORE2 Base Address |

- [ISS CSI2 PHY Register Summary: \[1\]](#)

8.2.4 ISS CCP2

8.2.4.1 ISS CCP2 Environment

8.2.4.1.1 ISS CCP2 Protocol and Data Formats

This section describes the CCP2 protocol and data formats. The CCP2 receiver is compatible with the *SMIA CCP2 Specification v1.0* and the *MIPI CSI1 Specification*. [Table 8-48](#) describes the I/O for serial interface CCP2.

Table 8-48. I/O Description for Serial Interface CCP2

| Signal Name | | I/O ⁽¹⁾ | Description |
|-------------|------------|--------------------|---------------------------------------------|
| ccp2_datp | CAM_S_DATA | I | Serial data input. Configurable. |
| ccp2_datn | | | |
| ccp2_strbp | CAM_S_CLK | I | Serial clock or strobe input. Configurable. |
| ccp2_strbn | | | |

⁽¹⁾ I = Input; O = Output

From the device point of view, the CCP2 interface comprises four differential inputs representing two effective signals: the serial data and the clock.

The CCP2 receiver is a serial interface to an image sensor. Signals from the camera are serial input data (CAM_S_DATA) and a clock/strobe signal (CAM_S_CLK).

8.2.4.1.1.1 ISS CCP2 Synchronization Codes

Each frame is clearly identified by four unique 32-bit synchronization codes: frame start, frame end, line start, and line end, which are embedded in the serial bitstream. The logical channel identification number is also encoded in the synchronization codes.

- Frame-start code (FSC): Identifies the start of a new frame
- Line-start code (LSC): Identifies the start of a new line and is received for every line, except the first line, that starts with an FSC
- Line-end code (LEC): Identifies the end of a line and is received for every line, except the last line, that ends with an FEC
- Frame-end code (FEC): Identifies the end of the last line and the end of the current frame

8.2.4.1.1.2 ISS CCP2 False Synchronization Code Protection

CCP2 supports false synchronization protection (FSP). Additional bytes after the JPEG stream can be written to the SDRAM. They do not prevent JPEG encode and there is no need to preserve them.

8.2.4.1.1.3 ISS CCP2 Image Data Operating Modes and Alignment Constraints

The CCP2 receiver interface has several image data operating modes (see [Table 8-49](#)). The EXP_x formats (where x = 8, 16, or 32) are used to expand data up to 8, 16, or 32 bits by padding data with zeros. The Data Size Increase in Memory column indicates memory overhead versus format without data expansion and/or DPCM compression.

Table 8-49. ISS CCP2 Image Data Operating Modes and Alignment Constraints

| CCP2_LCx_CT RL[7:2] Format | CCP2 Data Format | Bits per Pixel (bpp) (When sending data to memory, N/A when sending to VP) | Data Size Increase in Memory. (When negative, data compression present) | 2D Mode Availability ⁽¹⁾ | Comments |
|----------------------------------|---------------------------|------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|----------------------------------------|-----------------------|
| 0x0 | YUV4:2:2 big endian | 16 | 0% | Yes | |
| 0x1 | YUV4:2:2 little endian | 16 | 0% | Yes | |
| 0x2 | YUV4:2:0 | 12 | 0% | Yes | |
| 0x3 | YUV4:2:2 + VP | N/A, data are sent to VP, YUV4:2:2 + VP = RAW8 + VP | N/A | Yes | |
| 0x3 | RAW8 + VP | N/A, data are sent to VP, YUV4:2:2 + VP must be used to output RAW8 + VP to memory | N/A | Yes | |
| 0x4 | RGB444 + EXP16 | 16 | 50% | Yes | |
| 0x5 | RGB565 | 16 | 0% | Yes | |
| 0x6 | RGB888 | 24 | 0% | Yes | |
| 0x7 | RGB888 + EXP32 | 32 | 33% | Yes | |
| 0x8 | RAW6 + EXP8 | 8 | 33% | Yes | |
| 0x9 | RAW6 + DPCM10 + EXP16 | 16 | 167% | Yes | DPCM decompression |
| 0xA | RAW6 + DPCM10 + VP | N/A, data are sent to VP | N/A | Yes | DPCM decompression |

⁽¹⁾ If 2D mode is available, there are no supplementary constraints on data width. 2D mode does not apply when sending to the video port (VP).

Table 8-49. ISS CCP2 Image Data Operating Modes and Alignment Constraints (continued)

| CCP2_LCx_CT RL[7:2] Format | CCP2 Data Format | Bits per Pixel (bpp) (When sending data to memory, N/A when sending to VP) | Data Size Increase in Memory. (When negative, data compression present) | 2D Mode Availability⁽¹⁾ | Comments |
|-------------------------------------------|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|-----------------------------------------------|-----------------------|
| 0xB | RAW10 -> RAW6 DPCM | 6 | -40% | Yes | DPCM compression |
| 0xC | RAW7 + EXP8 | 8 | 14% | Yes | |
| 0xD | RAW7 + DPCM10 + EXP16 | 16 | 128% | Yes | DPCM decompression |
| 0xE | RAW7 + DPCM10 + VP | N/A, data are sent to VP | N/A | Yes | DPCM decompression |
| 0xF | RAW10 -> RAW6 DPCM + EXP8 | 8 | -25% | Yes | DPCM compression |
| 0x10 | RAW8, this mode can be used to output RAW6 and RAW7 | 8 | 0% | Yes | |
| 0x11 | RAW8 + DPCM10 + EXP16 | 16 | 100% | Yes | DPCM decompression |
| 0x12 | RAW8 + DPCM10 + VP | N/A, data are sent to VP | N/A | Yes | DPCM decompression |
| 0x13 | RAW10 -> RAW7 DPCM | 7 | -30% | Yes | DPCM compression |
| 0x14 | RAW10 | 10 | 0% | Yes | |
| 0x15 | RAW10 + EXP16 | 16 | 60% | Yes | |
| 0x16 | RAW10 + VP | N/A, data are sent to VP | N/A | Yes | |
| 0x17 | RAW10 -> RAW7 DPCM + EXP8 | 8 | -20% | Yes | |
| 0x18 | RAW12 | 12 | 0% | Yes | |
| 0x19 | RAW12 + EXP16 | 16 | 33% | Yes | |
| 0x1A | RAW12 + VP | N/A, data are sent to VP | N/A | Yes | |
| 0x1B | RAW10 -> RAW8 DPCM | 8 | -20% | Yes | DPCM decompression |
| 0x1C | JPEG, 8-bit data | N/A | 0% | Yes | |
| 0x1D | JPEG, 8-bit data + FSP | N/A | 0% | Yes | |
| 0x1E | RAW10 -> RAW8 DPCM | 8 | -20% | Yes | Data right shift |
| 0x1F | RAW8 DPCM12 -> RAW12 + VP | N/A, data are sent to VP | N/A | Yes | |
| 0x20 | RAW10 -> RAW8 ALAW | 8 | -20% | Yes | |
| 0x21 | RAW8 DPCM10 -> ALAW | 8 | -20% | Yes | |

NOTE:

- Padding data of a 32-bit pixel data stream is handled the same way regardless of the programmed format. Therefore, there is no increase or decrease in storage because it is not compressed or decompressed.
 - EXP8 = Data expansion to 8 bits, padding with zeros
 - EXP16 = Data expansion to 16 bits, padding with alpha or zeros
- [CCP2_LCx_CTRL](#)[15:8] ALPHA can be used to set an alpha value.
- For RGB444 + EXP16:
- data_out[31:28] = ALPHA [3:0]
 - data_out[15:12] = ALPHA [3:0]
- EXP32 = Data expansion to 32 bits, padding with alpha
- [CCP2_LCx_CTRL](#)[15:8] ALPHA can be used to set an alpha value.
- For RGB888 + EXP32: data_out[31:24] = ALPHA [7:0]
- FSP = False synchronization code protection decoding. Applies only to JPEG8 data format.
 - VP = Output to the video-preprocessing hardware is enabled. Programmers must ensure that only one logical channel is enabled to the video preprocessing hardware. The behavior of the hardware is unpredictable if several logical channels to the video preprocessing hardware are enabled simultaneously.
 - DPCM10 = Data decompression to 10 bits. Applies only to RAW6, RAW7, and RAW8 data formats; disabled if [CCP2_CTRL](#)[4] MODE = 0.
 - Padding is handled the same way regardless of the programmed format.
-

NOTE: Data written by CSI2 can be read back by the CCP2 read channel. Some constraints apply (see [Table 8-52](#)).

8.2.4.1.1.4 ISS CCP2 Pixel Data Format

This section summarizes how the CCP2 pixel data formats are transmitted over the serial interface and how the pixels are reconstructed, stored in memory, or passed to the video port.

The CCP2 receiver can cope with all data formats if the data line length sent through the CS1/CCP2 physical protocol is a multiple of 32 bits. This condition is required for the CCP2 receiver to work correctly.

However, some data formats impose stronger line-length constraints to finish pixel reconstruction correctly at the end of the lines. This is imposed by CCP2 protocol-specific requirements, and not the CCP2 receiver. If CCP2 protocol constraints are not respected:

- Only the pixels reconstructed last in every line are erroneous. The missing bits are replaced with zeros to perform pixel reconstruction.
- The FW_IRQ interrupt is triggered.

8.2.4.1.1.4.1 ISS CCP2 YUV Operating Modes

NOTE: Although there are different possibilities of endianness in the bitstream, the device as a whole typically works in little-endian format. Therefore, the use of little-endian format is recommended.

8.2.4.1.1.4.1.1 ISS CCP2 YUV4:2:2

The YUV4:2:2 data format can be stored to memory in little- or big-endian format. The line length sent through the CCP2 receiver protocol must be a multiple of 32 bits.

YUV4:2:2 data format can also be sent to the video port.

YUV4:2:2 + VP is used to output RAW8 data to the video port: YUV4:2:2 + VP is equivalent to RAW8 + VP. [Figure 8-10](#) and [Figure 8-11](#) show big-endian and little-endian YUV4:2:2 format, respectively. Set [CCP2_LCx_CTRL\[7:2\] FORMAT](#) to 0x0 to select YUV4:2:2 big-endian mode and to 0x1 for YUV4:2:2 little-endian mode.

Figure 8-10. ISS CCP2 YUV4:2:2 Big Endian

Figure 8-11. ISS CCP2 YUV4:2:2 Little Endian

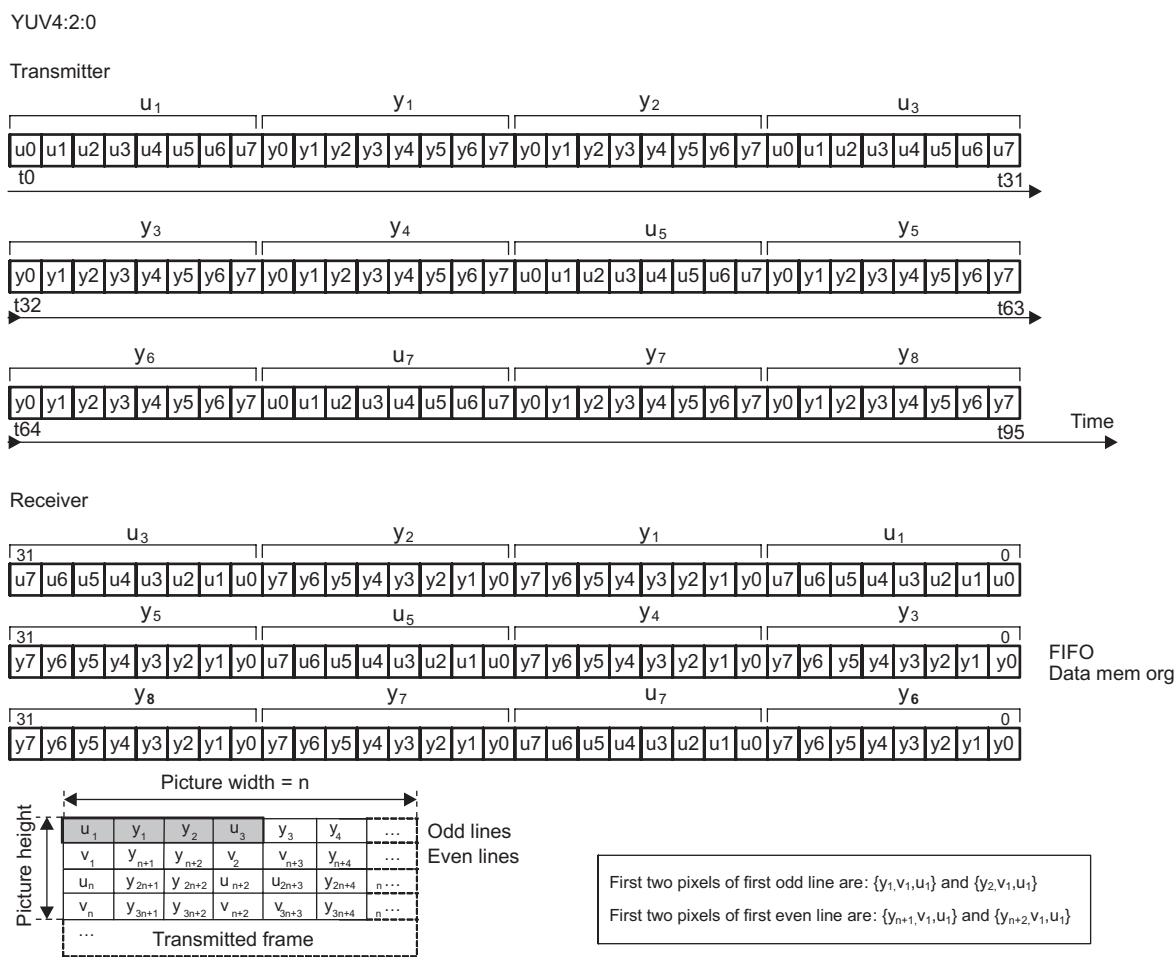

8.2.4.1.1.4.1.2 ISS CCP2 YUV4:2:0

The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. Furthermore, the line length all together sent by the CCP2 receiver is a multiple of 3 x 32 bits and the number of lines is even to correctly finish the pixel reconstruction.

The line structure is different for odd and even lines. Odd lines transport the U component, while even lines contain the V component. This is shown in Figure 8-12. Set CCP2_LCx_CTRL[7:2] FORMAT to 0x3 to select YUV4:2:0 mode.

Figure 8-12. ISS CCP2 YUV4:2:0

camss-053

8.2.4.1.1.4.2 ISS CCP2 RGB Operating Modes

8.2.4.1.1.4.2.1 ISS CCP2 RGB888

RGB888 data format can be output to memory in two formats: without data expansion and with data expansion.

If data expansion is used, the value of the 8 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. The line length all together sent by the CCP2 receiver is a multiple of 3 x 32 bits to finish pixel reconstruction correctly.

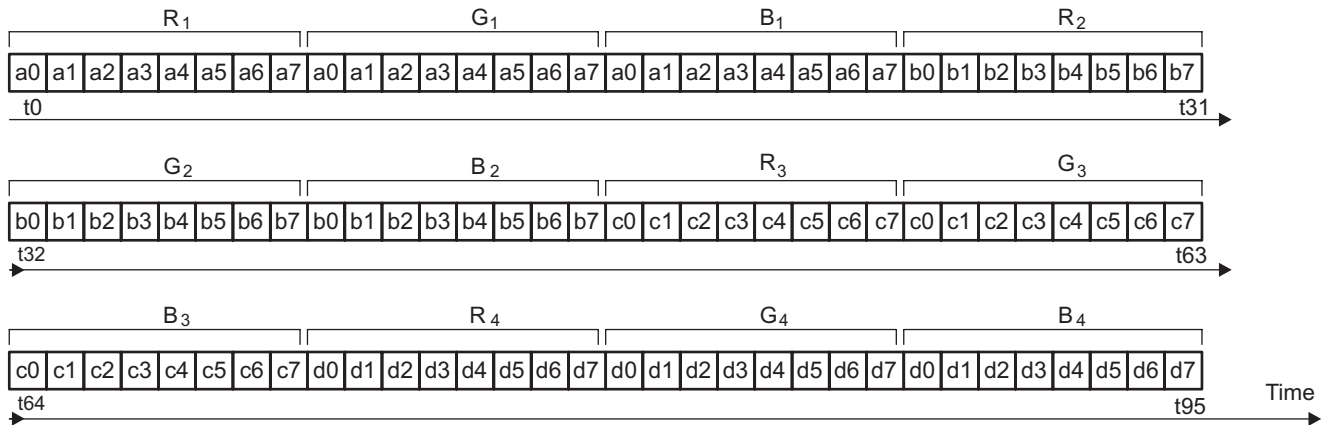

Figure 8-13 is an example of RGB888 format. Set CCP2_LCx_CTRL[7:2] FORMAT to 0x6 to select RGB888 mode (24 bits) or to 0x7 to expand RGB888 over 32 bits.

Figure 8-13. ISS CCP2 RGB888

RGB888

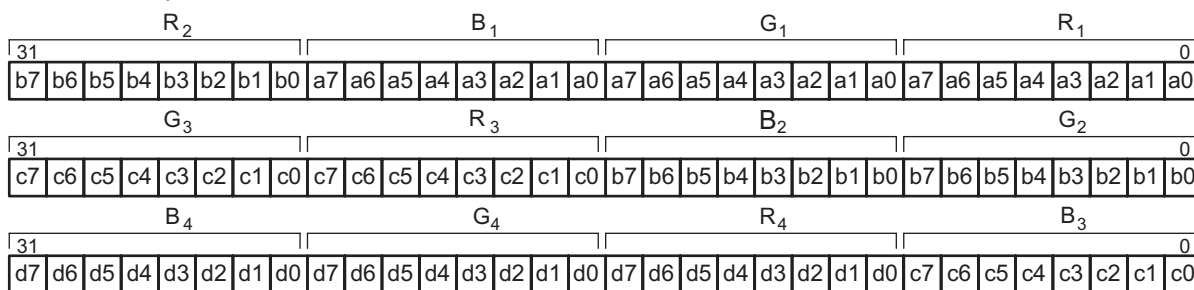

Line width must be a multiple of three 32-bit words.

Transmitter

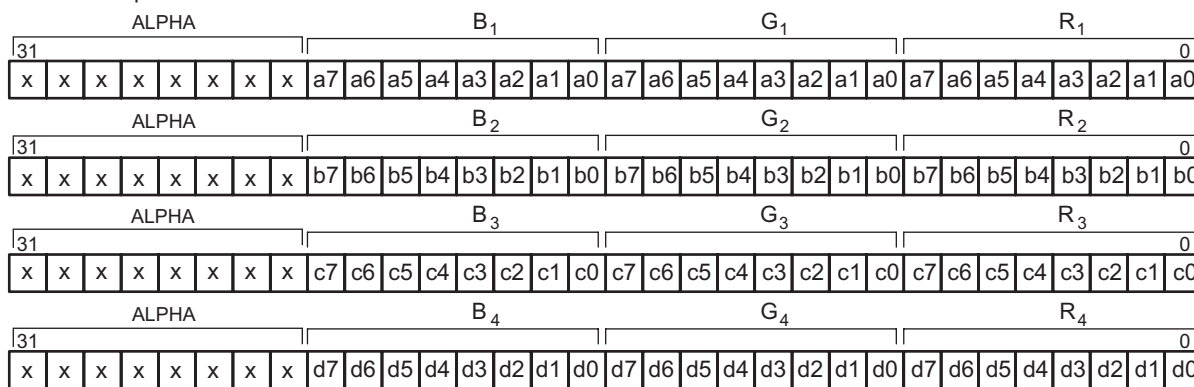

Receiver

Without data expansion

With data expansion

camss-054

8.2.4.1.1.4.2.2 ISS CCP2 RGB565

For RGB565, the line length sent through the CCP2 receiver protocol is a multiple of 32 bits (see Figure 8-14). Set `CCP2_LCx_CTRL[7:2] FORMAT` to 0x6 to select RGB565 mode.

Figure 8-14. ISS CCP2 RGB565

8.2.4.1.1.4.2.3 ISS CCP2 RGB444

RGB444 data format is output to memory with data expansion. If data expansion is used, the value of the 4 upper bits is programmable and can be set with an alpha value for computer graphics applications. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits (see Figure 8-15). Set `CCP2_LCx_CTRL[7:2] FORMAT` to 0x4 to select RGB444 mode (12 bits expanded to 16).

Figure 8-15. ISS CCP2 RGB444

8.2.4.1.1.4.3 ISS CCP2 RAW Bayer Operating Modes

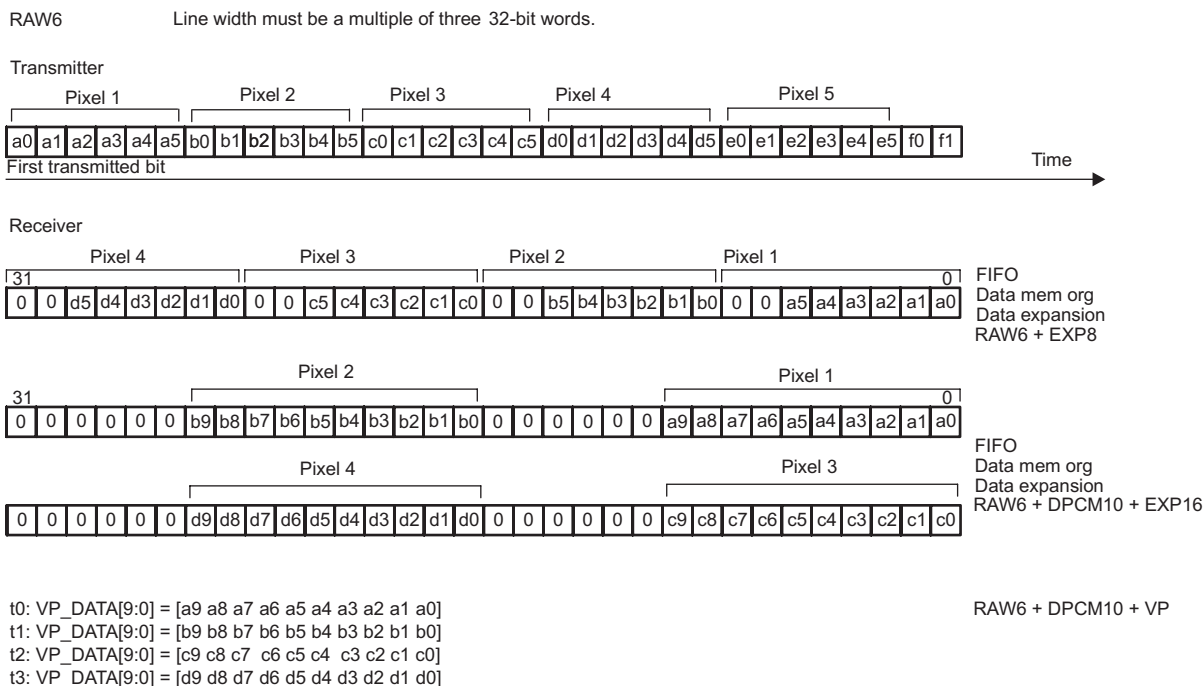

NOTE: For more information about packed RAW data, see Section 8.2.4.3.5.1, *ISS CCP2 Read Data From Memory*.

8.2.4.1.1.4.3.1 ISS CCP2 RAW6

RAW6 data format can be output to memory in two formats: without data expansion and with data expansion. The line length sent through the CSI receiver protocol is a multiple of 32 bits. The line all together sent by the CCP2 receiver is a multiple of 3 x 32 bits to finish pixel reconstruction correctly (the lowest common multiple of 32 and 6 is 96; that is, 3 x 32 bits).

Figure 8-16 shows the RAW6 format. Set `CCP2_LCx_CTRL[7:2] FORMAT` to:

- 0x8 to select RAW6 mode expanded to 8-bit
- 0x9 to select RAW6 mode with DPCM decompression
- 10-bit and expansion to 16-bit
- 0xA to select RAW6 mode with DPCM decompression to 10-bit to video port

Figure 8-16. ISS CCP2 RAW6

NOTE: Use RAW8 data format to output RAW6 data format to memory.

8.2.4.1.1.4.3.2 ISS CCP2 RAW7

RAW7 data format can be output to memory in two formats: without data expansion and with data expansion. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. The line length all together sent by the CCP2 receiver is a multiple of 7 x 32 bits to finish the pixel reconstruction correctly (the lowest common multiple of 32 and 7 is 224; that is, 7 x 32 bits).

Figure 8-17 shows the RAW7 format. Set `CCP2_LCx_CTRL[7:2]` FORMAT to:

- 0xC to select RAW7 mode expanded to 8-bit
- 0xD to select RAW7 mode with DPCM decompression to 10-bit and expansion to 16-bit
- 0xE to select RAW7 mode with DPCM decompression to 10-bit to video port

Figure 8-17. ISS CCP2 RAW7

NOTE: Use RAW8 data format to output RAW7 data format to memory.

8.2.4.1.1.4.3.3 ISS CCP2 RAW8

RAW8 data format can be output to memory. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits.

Figure 8-18 shows RAW8 format. Set `CCP2_LCx_CTRL[7:2] FORMAT` to:

- 0x10 to select RAW8
- 0x11 to select RAW8 mode with DPCM decompression to 10-bit and expansion to 16-bit
- 0x12 to select RAW8 mode with DPCM decompression to 10-bit to video port
- 0x20 to select RAW8 with A-Law decompression to RAW10

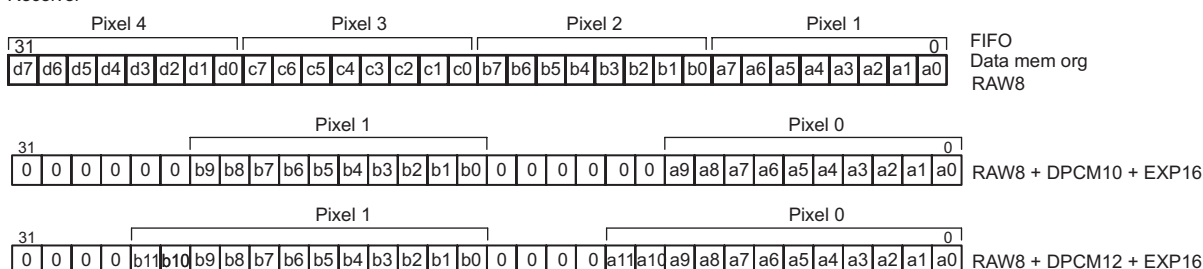

Figure 8-18. ISS CCP2 RAW8

RAW8 Line width must be a multiple of one 32-bit word.

Transmitter

Receiver

t0: VP_DATA[9:0] = [a7 a6 a5 a4 a3 a2 a1 a0]

t1: VP_DATA[9:0] = [b7 b6 b5 b4 b3 b2 b1 b0]

t2: VP_DATA[9:0] = [c7 c6 c5 c4 c3 c2 c1 c0]

t3: VP_DATA[9:0] = [d7 d6 d5 d4 d3 d2 d1 d0]

RAW8 + VP

t0: VP_DATA[9:0] = [a9 a8 a7 a6 a5 a4 a3 a2 a1 a0]

t1: VP_DATA[9:0] = [b9 b8 b7 b6 b5 b4 b3 b2 b1 b0]

t2: VP_DATA[9:0] = [c9 c8 c7 c6 c5 c4 c3 c2 c1 c0]

t3: VP_DATA[9:0] = [d9 d8 d7 d6 d5 d4 d3 d2 d1 d0]

RAW8 + DPCM10 + VP

camss-059

NOTE: Use YUV4:2:2 + VP to output RAW8 data to the video port: YUV4:2:2 + VP is equivalent to RAW8 + VP.

8.2.4.1.1.4.3.4 ISS CCP2 RAW10

RAW10 data format can be output to memory in two formats: without data expansion and with data expansion. If data expansion is used, the 10-bit data are padded with 0s on a 16-bit word. The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. Furthermore, the line length all together sent by the CCP2 receiver is a multiple of 5 x 32 bits to finish pixel reconstruction correctly (the lowest common multiple of 32 and 10 is 320; that is, 10 x 32 bits).

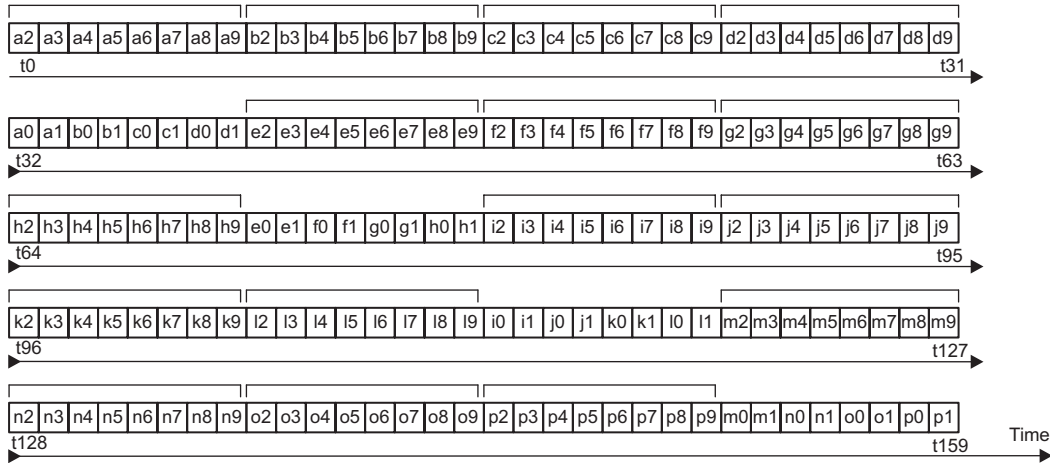

RAW10 data format can be sent to the video port. [Figure 8-19](#) shows the RAW10 format. Set `CCP2_LCx_CTRL[7:2] FORMAT` to:

- 0x14 to select RAW10
- 0x13 to select RAW10 mode with DPCM compression to 7-bit
- 0x16 to select RAW10 mode to video port
- 0x17 with DPCM compression to 7-bit with expansion to 8-bit
- 0x1B to select RAW10 compressed to 8-bit
- 0xB with DPCM compression to 6-bit
- 0xF to select RAW10 compressed to 6-bit with expansion to 8-bit
- 0x1E to select RAW10 compressed to 8-bit
- 0x20 to select RAW10 with A-Law compression to RAW8

camss-060

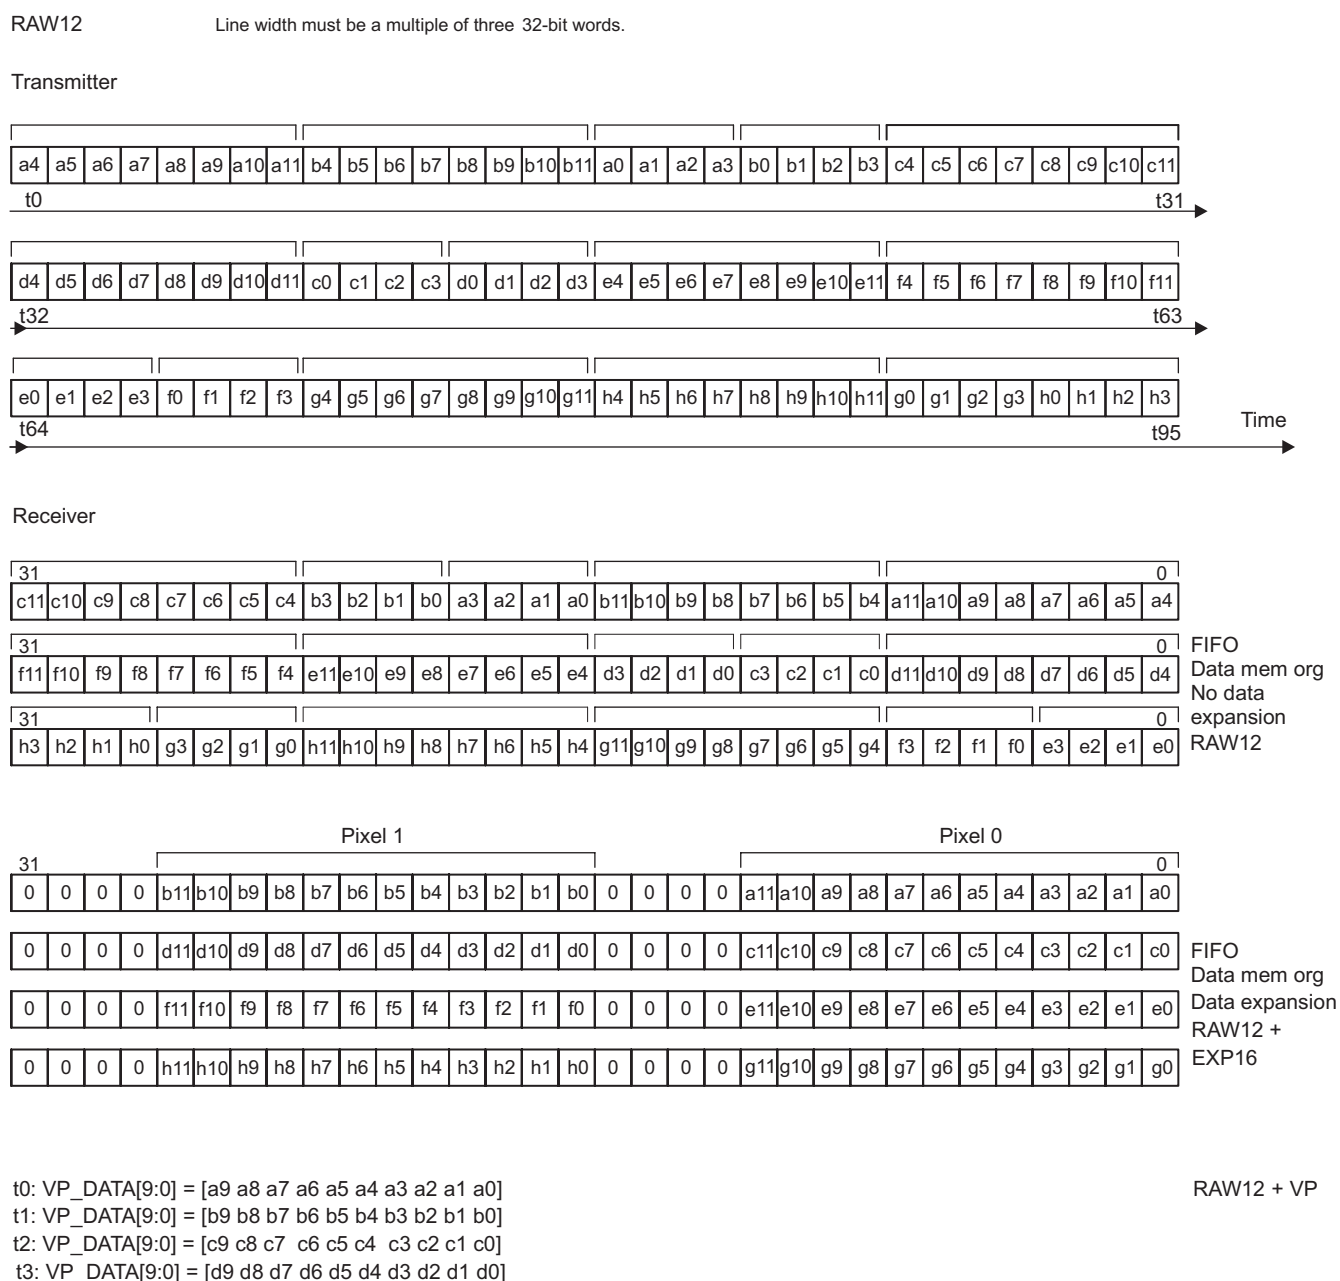

8.2.4.1.1.4.3.5 ISS CCP2 RAW12

RAW12 data format can be output to memory in two formats: without data expansion and with data expansion. If data expansion is used, the 12-bit data are padded with 0s on a 16-bit word. The line length sent through the CCP2 PHY is a multiple of 32 bits. The line length is a multiple of 3 x 32 bits to finish pixel reconstruction correctly (the lowest common multiple of 32 and 12 is 96; that is, 3 x 32 bits).

RAW12 data format can be sent to the video port. Figure 8-20 shows RAW12 format. Set `CCP2_LCx_CTRL[7:2] FORMAT` to:

- 0x18 to select RAW12
- 0x19 to select RAW12 mode with expansion to 16-bit
- 0x1A to select RAW12 mode to video port
- 0x17 with DPCM compression to 7-bit with expansion to 8-bit

Figure 8-20. ISS CCP2 RAW12

8.2.4.1.1.4.4 ISS CCP2 JPEG8 Operating Modes

The line length sent through the CCP2 receiver protocol is a multiple of 32 bits. The FSP code insertion on the transmitter side automatically ensures this line length. It is impossible to know in advance the size of a compressed stream. [Figure 8-21](#) shows the JPEG8 and JPEG8 FSP format. Set `CCP2_LCx_CTRL[7:2] FORMAT` to 0x1C to select JPEG8 format, or to 0x1D to select JPEG8 format with FSP.

Figure 8-21. ISS CCP2 JPEG8 and JPEG8 FSP

In JPEG8 mode, the JPEG encoder on the sensor side must avoid generating data equal to the synchronization code and must deliver a synchronization-code-free bitstream for line-start and line-end before and after the transmitted data. For more information, see [Section 8.2.4.1.1.2, ISS CCP2 False Synchronization Protection Code](#).

8.2.4.1.1.5 ISS CCP2 Data Transfer Through Write Master Port

The CCP2 receiver module uses its 64-bit master interface to transfer the data stored in the FIFO. The system can set the burst size to be used in the `CCP2_CTRL BURST` register. The recommended burst size is 128 bytes (0x4: 16 x 64-bit bursts are the most efficient for memory output); other sizes should be used only when issues are faced. The module tries to burst data whenever possible to increase system performance and save power. The module uses the appropriate register-selected burst size when the conditions (address is properly aligned, there is enough data in the FIFO to finish the line) are met; otherwise, it uses single requests.

For example, if the line consists of 50 pixels of 64-bit data and `BURST = 0x4` (16 x 64-bit bursts), the module generates four times 16 x 64-bit bursts to transmit the whole line. The FIFO can have information about only two different lines.

The CCP2 engine supports tag count. The count is configurable through a register at the top level of the ISS (see [Section 8.1.3, ISS Register Manual](#)).

8.2.4.2 ISS CCP2 Integration

[Figure 8-22](#) is an overview of the integration of the CCP2 interface in the device. The figure shows the CCP2 receiver top-level block diagram. The CCP2 receiver receives serial data from a CCP2-compatible image sensor, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the VP interface (which is connected to the video preprocessing hardware [ISP]) or the ISS interconnect. The CCP2 can also get its data from memory using a dedicated interface read master port when this feature is enabled at compile time.

Figure 8-22. ISS CCP2 Integration

camss-353bu

NOTE: Because CCP2 and CSI2-B share pins, they cannot be used simultaneously. For ISP source select, see [Section 8.1.1, ISS Integration](#), for ISP registers input selection and for top-level input select settings.

For power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

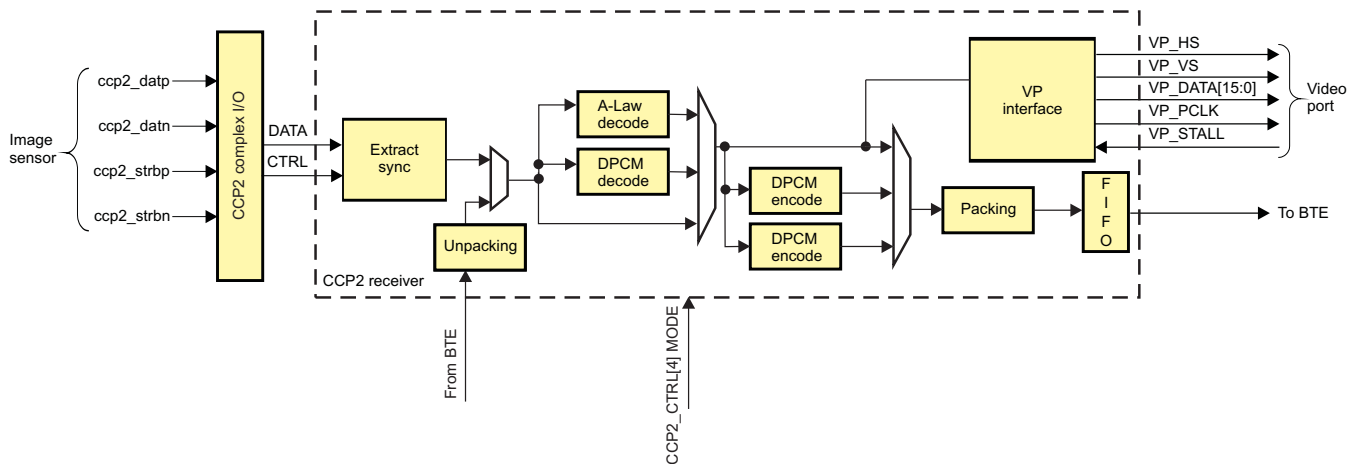

8.2.4.3 ISS CCP2 Functional Description

8.2.4.3.1 ISS CCP2 Overview

Figure 8-23 is the top-level block diagram of the CCP2 receiver. The CCP2 receiver receives serial data from a CCP2-compatible image sensor, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the VP interface (which is connected to the video preprocessing hardware [ISP]) or the ISS interconnect. The CCP2 can also read data from memory getting burst packets from the BTE when this feature has been enabled at compile time. For read data from memory, see Section 8.2.4.3.5, *ISS CCP2 Memory Read Channel*.

The CCP2 receiver video port interface is connected to the video preprocessing hardware.

Figure 8-23. ISS CCP2 Receiver Block Diagram

camss-493

8.2.4.3.2 ISS CCP2 PHY

The CCP2 receiver does not connect directly to a sensor (see Section 8.2.3, *ISS CSI2 PHY*). It uses a complex I/O physical layer. The CCP2 complex I/O is shared with the CSI2-B receiver. The CSI2-B/CCP2 PHY is powered up by configuring the CSI2 receiver configuration register. For more information about the configuration of the PHY, see Section 8.2.3.2.1, *ISS CSI2 PHY Functional Configuration*. The CCP2 serial interface is a unidirectional differential serial interface with two options for the PHY: data/clock or data/strobe signals. After the PHY is configured and initialization is done, the CCP2 mode can be selected and controlled by the CCP2_CTRL[1] MODE bit.

8.2.4.3.2.1 ISS CCP2 Data/Clock Signaling

Data/clock signaling consists of two parallel signals: data and data clock.

- The data signal carries bit serial data. The CCP2 transmitter writes the data on each falling edge of the clock. The data are usually transmitted byte-wise, least-significant bit (LSB) first.
- The data clock signal carries the clock signal. The CCP2 transmitter writes the data on each falling edge of the clock. The CCP2 receiver reads the data on the rising edge of the clock.

8.2.4.3.2.2 ISS CCP2 Data/Strobe Signaling (CCP2 Only)

Data/strobe signaling consists of two parallel signals: data and data strobe.

- The data signal carries bit serial data.
- The data strobe signal carries the strobe signal. It toggles when the data signal does not change state.

The data signal or the strobe signal changes between 2 data bits. The data and strobe signals must not change simultaneously. The data and strobe signals are used in the receiver to reconstruct the transmission clock. Both fronts of the reconstructed clock are used to sample the data. Set the [CCP2_CTRL\[4\] MODE](#) bit and see [Section 8.2.3, ISS CS/2 PHY](#), to set the data/clock or data/strobe function.

8.2.4.3.3 ISS CCP2 VP Interface

[Table 8-50](#) summarizes the video interface signals. The video interface connects the CCP2 receiver module to the video preprocessing hardware (ISP). The interface is connected to a 16-bit video port. On the other side of the video port is the ISIF inside the ISP. The ISIF also uses the signals listed in [Table 8-50](#) to synchronize pixel data sent to it by the CCP2 receiver.

Table 8-50. ISS CCP2 Video interface Signals

| Pin | Type ⁽¹⁾ | Description |
|---------------|---------------------|----------------------------------------------------------|
| VP_HS | O | Line trigger output signal |
| VP_VS | O | Frame trigger output signal |
| VP_DATA[15:0] | O | Parallel output data: bits 0 to 15 |
| VP_PCLK | O | Video port pixel clock. The frequency can be configured. |
| VP_STALL | I | Stalls data flow when data is read from memory |

⁽¹⁾ I = Input; O = Output

When data is read from memory and sent to the video port, the data flow can be stalled by asserting the VP_STALL signal. Doing so does not overflow internal FIFOs: the CCP2 module adapts its read rate automatically.

The response time to the VP_STALL signal must not exceed two cycles: when VP_STALL is asserted, the CCP2 module can send 0, 1, or 2 pixels to the video port.

VP_STALL is asserted and deasserted synchronous to the functional clock.

NOTE: Stalling the video port for data received from the sensor may lead to internal overflows; VP_STALL must not be used for this purpose.

The pixel clock is generated from the functional clock. Clock pulses are gated based on the selected clock division factor and pixel availability. In other words, software must set the CCP2 receiver to ensure that the pixel clock:

- Never exceeds what the ISP can support: the top value set in the [CCP2_CTRL\[31:15\] FRACDIV](#) bit field
- Is sent only when valid pixels or blanking data must be sent

Also, software must set the number of clock pulses during horizontal blanking periods using the [CCP2_CTRL1\[1:0\] BLANKING](#) bit field.

- The CCP2 receiver stops generating horizontal blanking clock pulses when the number of pulses defined in the [CCP2_CTRL1\[1:0\] BLANKING](#) bit field are generated or when data for the next line arrives from the sensor.
- Free-running horizontal blanking can be selected only when data comes from the sensor.
- When data comes from memory, the CCP2 receiver ensures that the number of horizontal blanking pulses defined in the [CCP2_CTRL1\[1:0\] BLANKING](#) bit field is received. The CCP2 receiver stops generating horizontal blanking clock pulses when then number of pulses defined in the [CCP2_CTRL1\[1:0\] BLANKING](#) bit field is generated or when data for the next line arrives from the sensor.

NOTE: To work properly, the ISP requires a minimum of eight clock cycles in the horizontal blanking period and a minimum of 16 lines in the vertical blanking period. The pixel clock can be gated only when these intervals are respected. This is required to flush the pipeline of the different ISP modules. Figure 8-24 shows VP_PCLK gating during blanking periods.

Figure 8-24. ISS CCP2 VP_PCLK Gating During Blanking Periods

Vertical blanking generation is controlled through the `CCP2_CTRL[9] VP_CLK_FORCE_ON` bit. The VP_PCLK clock is enabled during vertical blanking periods when this bit is set. This pushes pixels through the ISP processing pipe. It is needed, for example, when the ISP resizer uses the averager. Otherwise, hardware ensures only that at least four clock pulses are generated before the first pixel of each frame. It may be necessary for the clock to keep running after the frame end to flush internal pipelines. In that case, an interrupt request (IRQ) or status bit is typically present in the attached hardware that indicates when the VP_PCLK clock is no longer needed (for example, an end of processing interrupt). The module leaves the vertical blanking state when new data is received from the sensor or the memory read channel.

The configured pixel clock is used for active and blanking periods.

Table 8-51 shows how RAW and YUV data is sent over the video port. The data is sent to the ISIF if ISP is used. For the ISIF details about video port data, see Section 8.3 ISS: ISP.

Table 8-51. ISS CCP2 Video Port Data Mapping

| Format | Video Port DATA[15:0] | | | | | | | | | | | | | | | |

| | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | Y7 | Y6 | Y5 | Y4 | Y3 | Y2 | Y1 | Y0 |

8.2.4.3.4 ISS CCP2 Data Compression

The data compression technique used is DPCM and pulse code modulation (PCM).

The CCP2 receiver performs on-the-fly compression and decompression. The compressed/decompressed data is passed to the video preprocessing hardware or stored in memory.

The data compression method is lossy and does not require any information outside the current encoded/decoded line. This means that all the image lines can be encoded and decoded separately.

Two different predictors are used:

- The simple predictor
This predictor uses only the previous same color component value as a prediction value. Therefore, only 2-pixel memory is required.
- The advanced predictor
This predictor uses four previous pixel values, when the prediction value is evaluated. This means that also the other color component values are used, when the prediction value is defined.

The preferable use is that the simple predictor is used with 10 bits to 8 bits or 12 bits to 8 bits conversion (10810 or 12812) and the advanced predictor is used with 10 bits to 7 bits and 10 bits to 6 bits conversions (10710 and 10610). The advanced predictor gives slightly better prediction for pixel value; thus, the image quality can be improved with it. Because the simple predictor is very simple, the processing power and memory requirements are reduced with it, when the image quality is already high enough.

Select the predictor with the [CCP2_LCx_CTRL\[10\]](#) DPCM_PRED bit.

8.2.4.3.5 ISS CCP2 Memory Read Channel

The memory channel can perform the following operations:

- Reads data from memory. It is unpacked and DPCM or A-Law decompressed if necessary.
- Sends data to the video preprocessing hardware
- Sends data back to memory. It can be DPCM or A-Law compressed and packed before it is sent to memory.

It cannot receive its input data directly from the sensor, and the logical channels are disabled when the memory channel is enabled.

[Table 8-52](#) summarizes supported modes for memory-to-memory operations.

NOTE: Video port and memory destinations are mutually exclusive.

Table 8-52. ISS CCP2 Memory-to-Memory Supported Operations

8.2.4.3.5.1 ISS CCP2 Read Data From Memory

Figure 8-25 shows the data organization in memory.

Figure 8-25. ISS CCP2 Data Organization in Memory

The user chooses the start address and the line length using the [CCP2_LCM_SRC_ADDR](#) and [CCP2_LCM_SRC_OFST](#) registers. The image start address normally must point to the beginning of a line because of packing constraints. However, it does not necessarily point to the first line of the frame in memory. The [CCP2_LCM_VSIZE\[27:16\]](#) COUNT bit field specifies the total line count to be read from memory.

It is also possible to skip a certain pixel count ([CCP2_LCM_HSIZE\[11:0\]](#) SKIP) from the start of the line. Thus, they are not sent to the video port or back to memory. The [CCP2_LCM_HSIZE\[27:16\]](#) COUNT bit field specifies the horizontal size of the image. The pixels after the right boundary of the image are not read from memory.

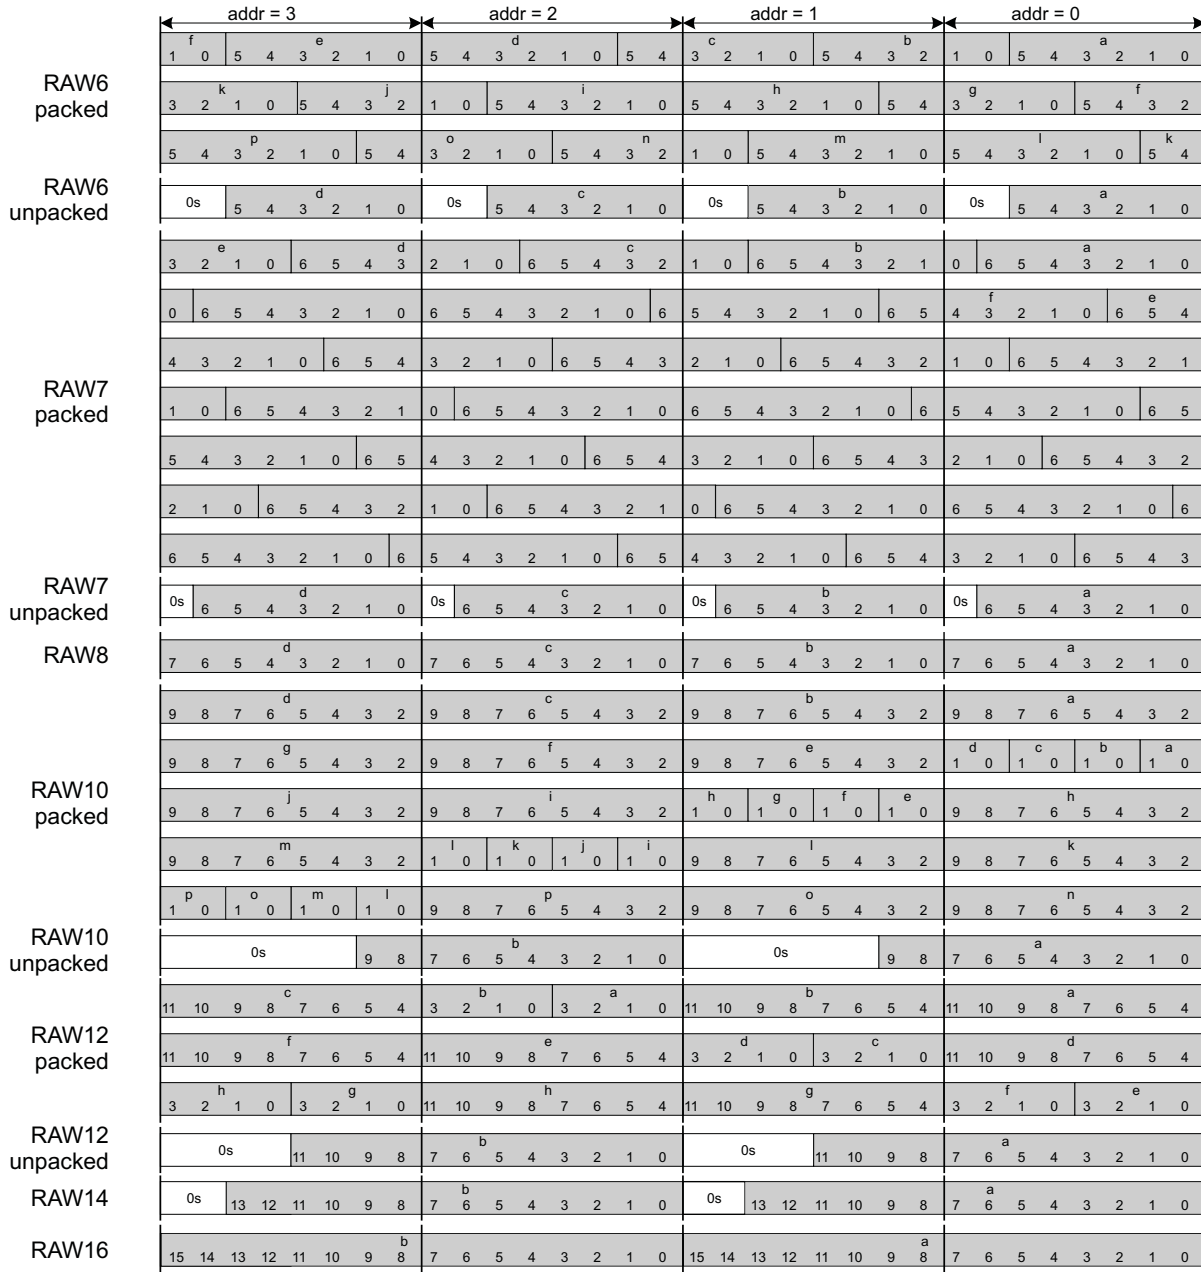

When data are sent to the video port, throughput is imposed by the selected VP_PCLK. Otherwise, it is imposed by the selected interconnect read port clock. The interconnect read rate can be throttled (limiting the maximum data read speed for memory-to-memory operation) using the [CCP2_LCM_CTRL\[4:3\]](#) READ_THROTTLE bit field. Therefore, it is possible to read the unused data at a higher rate than the used video port data rate. This provides better performance than framing the image in the video preprocessing hardware.

The data storage format in memory is defined by the [CCP2_LCM_CTRL\[18:16\]](#) SRC_FORMAT and [CCP2_LCM_CTRL\[23\]](#) SRC_PACK bit fields.

Not all I/O format combinations are valid. For more information, see [Table 8-52](#) and [Table 8-53](#).

[Figure 8-26](#) shows how data are packed in memory. Pixel order (left to right in the image) is alphabetical (a, b, c). Therefore, data storage is little endian.

Figure 8-26. ISS CCP2 Data Organization Packing in Memory

camss-506u

Table 8-54 summarizes the storage reduction versus unpacked format and image width restrictions when data packing is used. The image width applies to the data width multiple in pixels that must be stored to have storage reduction. Moreover, because each address is 8 bits long, the percentage shows how many bits out of 8 are to be packed in the empty space from another pixel address. A pixel is selected and split. One of the parts is put into another pixel address empty space. When unpacked, each pixel bit is stored continuously again.

Table 8-54. ISS CCP2 Data Packing Benefit and Constraints

| | Bits Per Pixel | | Storage Reduction | Width Multiple (Pixels) |
|------|----------------|----------|-------------------|-------------------------|
| | Packed | Unpacked | | |
| RAW6 | 6 | 8 | 25% | 16 |
| RAW7 | 7 | 8 | 13% | 3 |

Table 8-54. ISS CCP2 Data Packing Benefit and Constraints (continued)

| | Bits Per Pixel | | Storage Reduction | Width Multiple (Pixels) |
|-------|----------------|----------|-------------------|-------------------------|
| | Packed | Unpacked | | |
| RAW8 | 8 | 8 | 0% | 4 |
| RAW10 | 10 | 16 | 38% | 16 |
| RAW12 | 12 | 16 | 25% | 8 |

8.2.4.3.5.2 ISS CCP2 Memory Read Port Burst Generation

Hardware always uses the largest possible burst size according to the setup. The amount of data read from memory can be higher than what is actually used by the CCP2 receiver. Only full 64-bit burst words are read back from memory. [Figure 8-27](#) shows the data organization and the relationship between the different parameters controlling the burst generation.

Figure 8-27. ISS CCP2 Data Organization in Memory**NOTE:**

- A minimum burst size of 2 must be selected for correct operation.
- The HWORDS bit field must be even for correct operation.

The [CCP2_LCM_SRC_ADDR](#) register address of the first data to read is aligned to a 32-byte boundary. The read port fetches [CCP2_LCM_PREFETCH\[15:3\]](#) HWORDS of 64-bit words per line using the longest possible burst computed from the [CCP2_LCM_CTRL\[7:5\]](#) BURST_SIZE bit field and the remaining data to be fetched. Burst size of 128 bytes is preferred. When the CCP2 receiver is configured to fetch more data than required, extra data are dropped internally.

8.2.4.3.5.3 ISS CCP2 MFLAG Mechanism and Arbitration

The MFLAG mechanism allows a dynamic increase of the priority of CCP2 real-time traffic, when required, based on the fullness of the CCP2 DMA read and write buffers. Programmable buffer thresholds indicate when the local MFLAG signal is generated. The MFLAG signal is then provided to the L3 interconnect for granting or prioritizing OCP requests. The out band CCP2 MFLAG signal is asynchronous to any ongoing OCP transaction. The threshold corresponds to the fullness of the DMA buffer, and is defined by the following threshold parameters:

- High threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted). The value is set in the [CCP2_CTRL1\[30:24\]](#) LEVH register.

- Low threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted). The value is set in the [CCP2_CTRL1\[22:16\] LEVL](#) register.

8.2.4.3.5.4 ISS CCP2 Video Port

The video port always receives unpacked data. It can be enabled using the [CCP2_LCM_CTRL\[2\] DST_PORT](#) bit. Its clock can be selected with the [CCP2_CTRL\[31:15\] FRACDIV](#) bit field and gated or not during frame blanking periods using the [CCP2_CTRL\[9\] VP_CLK_FORCE_ON](#) bit.

The data format used by the video port is defined by the [CCP2_LCM_CTRL\[26:24\] DST_FORMAT](#) bit field. For a list of supported modes, see [Table 8-53](#).

8.2.4.3.5.5 ISS CCP2 Encode, Pack, and Store Data

This stage is used only when data are sent to memory. Memory destination is selected using the [CCP2_LCM_CTRL\[2\] DST_PORT](#) bit. The output data format is defined by the [CCP2_LCM_CTRL\[26:24\] DST_FORMAT](#) bit field and the [CCP2_LCM_CTRL\[31\] DST_PACK](#) bit. Not all possible combinations are supported; see [Table 8-52](#) for details.

The destination address and offset for the output data of the memory channel are set by the [CCP2_LCM_DST_ADDR](#) and [CCP2_LCM_DST_OFST](#) registers.

Because of alignment constraints on the interconnect port, the output image width restrictions in [Table 8-55](#) apply.

Table 8-55. ISS CCP2 Output Width Restrictions in Memory-to-Memory Operation

| Format | Bits per Pixel | Width Multiple of ⁽¹⁾ | Note |
|--------------|----------------|----------------------------------|-------------------------------------------------------------------------------------------------|
| RAW6 | 8 | 1 | Full 32-bit words are written at the end of the line. This last word can eventually include 0s. |
| RAW6 packed | 6 | 1 | |
| RAW7 | 8 | 1 | |
| RAW7 packed | 7 | 1 | |
| RAW8 | 8 | 1 | |
| RAW10 | 16 | 1 | |
| RAW10 packed | 10 | 16 | |
| RAW12 | 16 | 1 | Same constraints as RAW8 |
| RAW12 packed | 12 | 8 | |

⁽¹⁾ In continuous mode, lines must be multiples of 128 bits. In 2D mode, lines must start on 128-bit boundaries.

For example, when RAW6 packed data are written to memory, any output width is allowed. However, only full 32-bit words are written to memory. This eventually overwrites some data in memory at the end of a line.

The supported output width is restricted for packed RAW10 and RAW12 data because of the particular bit ordering in those formats (see [Figure 8-26](#)).

When the [DST_OFST](#) bit is set to 0, start of lines are aligned on 4-byte boundaries. When [DST_OFST](#) is not set to 0, data are aligned on 32-byte boundaries.

NOTE: The RAW6, RAW7, and DPCM data formats do not apply to the MIPI CSI1-compatible mode.

8.2.4.3.5.6 ISS CCP2 DPCM Decompression History

The DPCM compression algorithm can encode the difference between consecutive samples in a line instead of the actual samples value to reduce the amount of data to store. The drawback is that lines must always be decoded from the beginning (the first samples of a line are always encoded as PCM).

The CCP2 receiver has a mechanism to preserve the DPCM decode history for each line to avoid decoding the same samples multiple times when vertical frame division mode is used.

The typical use case (also known as vertical frame division mode) is when an image is wider than the ISP can process on the fly, but the image must be processed. Therefore, the image is cut into multiple vertical slices that are processed sequentially by the ISP. The slices are stitched together in the SDRAM after ISP processing through proper address generation in the ISP. Because of various alignment constraints in the ISP, the slices sent to ISP must overlap. Without preserving the DPCM history, all lines from the beginning of the second (and other consecutive) vertical slice would have to be recoded, which would lead to performance degradation.

Writing DPCM history information into the system memory is enabled by setting the `CCP2_LCM_HISTORY[16] EN_HIST_WR` bit. The `CCP2_LCM_HISTORY[15:0] HIST_EXPORT` bit field defines the position at which history data is written to memory. The position is counted from the beginning line. The first decoded pixel has position 0. The last decoded pixel has position `CCP2_LCM_HSIZE[14:0] SKIP + CCP2_LCM_HSIZE[30:16] COUNT - 1`. The `CCP2_LCM_HISTORY[15:0] HIST_EXPORT` bit field is used to choose the resume position and allows support of overlapping vertical slices. History data is written to the SDRAM at `ADDR = CCP2_LCM_DST_ADDR[31:5] ADDR + Y × 8` bytes (where Y is the line number). The CCP2 receiver always writes 8 bytes of history data per line to the SDRAM regardless of the chosen DPCM format. The CCP2 receiver uses the interface bursts to send history data to memory.

DPCM history data holds the decoded value of four samples. The CCP2 receiver exports samples of positions:

- `CCP2_LCM_HISTORY[15:0] HIST_EXPORT - 3`
- `CCP2_LCM_HISTORY[15:0] HIST_EXPORT - 2`
- `CCP2_LCM_HISTORY[15:0] HIST_EXPORT - 1`
- `CCP2_LCM_HISTORY[15:0] HIST_EXPORT`

Every sample is coded on 16 bits, and several MSBs are unused. The valid range for `CCP2_LCM_HISTORY[15:0] HIST_EXPORT` is `[3.. CCP2_LCM_HSIZE[14:0] SKIP + CCP2_LCM_HSIZE[30:16] COUNT - 1]`. History data can be exported even when data is not sent to the video port or ISS interconnect port (that is, `CCP2_LCM_HISTORY[15:0] HIST_EXPORT < CCP2_LCM_HSIZE[14:0] SKIP` is valid).

8.2.4.4 ISS CCP2 Programming Model

This section describes the programming model of the CCP2 receiver.

8.2.4.4.1 ISS CCP2 Programming Hardware Setup/Initialization

This section discusses the configuration of the CCP2 receiver required before image capture can begin. Before using the receiver, a CSIPHY initialization in CCP2 mode must be made for CSI2-B/CCP2 CAMERARX, which is associated with the CCP2 receiver. See [Section 8.2.3.2.3, ISS CCP2 and Link Initialization Sequence](#).

NOTE: The setup/initialization previously explained is valid only when the external sensor is used. If the user plans to use the logical memory channel (LCM) or debug mode (`CCP2_CTRL[13] DBG_EN = 0x1`) instead of the external sensor, this setup/initialization is not necessary.

8.2.4.4.1.1 ISS CCP2 Reset Behavior

On hardware or software reset of the ISS, all registers in the CCP2 receiver are reset to their reset values.

The two sources for a CCP2 software reset are:

- Global reset for the whole ISS – `ISS_HL_SYSCONFIG[0] SOFTRESET` bit
- Local reset, affecting only the CCP2 module. The reset is initiated by writing 0x1 in the `CCP2_SYSCONFIG[1] SOFT_RESET` bit. The reset done status can be checked by reading the `CCP2_SYSSTATUS[0] RESET_DONE` bit.

8.2.4.4.2 ISS CCP2 Programming Event and Status Checking

When an event occurs, the corresponding bit in the [CCP2_LC01_IRQSTATUS](#), [CCP2_LC23_IRQSTATUS](#), or [CCP2_LCM_IRQSTATUS](#) register is set. Each event can be individually masked using the [CCP2_LC01_IRQENABLE](#), [CCP2_LC23_IRQENABLE](#), or [CCP2_LCM_IRQENABLE](#) register. Masked events are not transmitted to the interrupt line, but the [CCP2_LC01_IRQSTATUS](#), [CCP2_LC23_IRQSTATUS](#), or [CCP2_LCM_IRQSTATUS](#) register is updated.

Events transmitted to the ISS interrupt merger can be mapped to the Cortex-A9 or Cortex-M3 MPU subsystem or DSP by unmasking [ISS_HL_IRQENABLE_SET_i\[\] CCP2_IRQj](#) (where $i = 0$ to 5 , $j = 0, 1, 2, 3$, and 8). Only the [ISS_HL_IRQENABLE_SET_5](#) output line is connected to the Cortex-A9 MPU interrupt controller, and only the [ISS_HL_IRQENABLE_SET_4](#) output line is connected to the DSP interrupt controller. The Cortex-M3 interrupt controller, however, is connected to all six output lines of [ISS_HL_IRQENABLE_SET_i](#) (where $i = 0$ to 5). To clear an event, the following actions are required:

- Clear the event at the CCP2 receiver level by writing 1 to the corresponding bit in the [CCP2_LC01_IRQSTATUS](#), [CCP2_LC23_IRQSTATUS](#), or [CCP2_LCM_IRQSTATUS](#) register.
- Events generated by the submodules and ISS top level clear it. Each event that generates an interrupt can be individually enabled by setting the appropriate bit in the [ISS_HL_IRQENABLE_SET_i](#) register. It is disabled by setting the appropriate bit in the [ISS_HL_IRQENABLE_CLR_i](#) register. When an event occurs, the corresponding bit in the [ISS_HL_IRQSTATUS_i](#) register is set, regardless of whether or not the event is enabled. Bits in the [ISS_HL_IRQSTATUS_i](#) registers are set only when an enabled event occurs. Software can clear a pending [HS_VS_IRQ](#) event by setting the appropriate bit [ISS_HL_IRQSTATUS_i\[17\] HS_VS_IRQ](#). Events generated by submodules are automatically cleared at ISS top level when they are cleared at submodule level.

8.2.4.4.3 ISS CCP2 Programming Register Accessibility During Frame Processing

There are two types of register accesses in the CCP2 receiver:

- Shadowed registers:
 - These registers/fields can be read and written (if the field is writable) at any time. However, written values take effect only at the start of a frame. Reads return the most-recent write, even though the settings are not used until the next start of frame.
 - The shadowed registers are:
 - [CCP2_LCx_CTRL](#)
 - [CCP2_LCx_CODE](#)
 - [CCP2_LCx_STAT_START](#)
 - [CCP2_LCx_STAT_SIZE](#)
 - [CCP2_LCx_SOF_ADDR](#)
 - [CCP2_LCx_EOF_ADDR](#)
 - [CCP2_LCx_DAT_SIZE](#)
 - [CCP2_LCx_DAT_PING_ADDR](#)
 - [CCP2_LCx_DAT_PONG_ADDR](#)
 - [CCP2_LCx_DAT_OFST](#)
- Busy-locked registers:
 - These registers/fields must not be written if the module is busy.
 - All register fields not listed as shadowed are busy-writable registers.

8.2.4.4.4 ISS CCP2 Programming Enable/Disable the Hardware

The CCP2 receiver is globally controlled by the [CCP2_CTRL](#) register. The bit fields in this register must not be modified when the CCP2 interface is active (except [CCP2_CTRL\[0\] IF_EN](#)).

[Table 8-56](#) and [Table 8-57](#) list the procedures to enable and disable, respectively, the interface.

Table 8-56. ISS CCP2 Interface Enable

| Step | Bit Field | Value |
|-----------------------------------------------------------------------------------------|--------------------|-------|
| Clear the interface. Data acquisition starts on the following FSC synchronization code. | CCP2_CTRL[0] IF_EN | 0x1 |
| Reset the output FIFO of the module; the reset is caused by the 0-to-1 edge transition. | CCP2_CTRL[0] IF_EN | 0x1 |

Table 8-57. ISS CCP2 Interface Disable

| Step | Bit Field | Value |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|-------|
| Disable interface. <ul style="list-style-type: none"> The interface is disabled immediately if CCP2_CTRL[3] FRAME = 0x0. If CCP2_CTRL[3] FRAME = 0x1 and CCP2_LCx_CTRL[2] CRC_EN = 0x0, the interface is disabled after the FEC synchronization code is received. If CCP2_CTRL[3] FRAME = 0x1 and CCP2_LCx_CTRL[2] CRC_EN = 0x1, the interface is disabled only after the 16-bit CRC checksum and 16-bit pad data is received. Before disabling the interface (IF_EN = 0), it is advised to disable all active channels by writing CCP2_LCx_CTRL[0] CHAN_EN = 0x0. Otherwise, if IF_EN = 0 is set during a vertical blanking period, the reception continues until the FEC synchronization code is received for all active channels. | CCP2_CTRL[0] IF_EN | 0x0 |

8.2.4.4.5 ISS CCP2 Programming Select the Signaling Scheme

Table 8-58 lists the procedure to select the signaling scheme.

Table 8-58. ISS CCP2 Select the Signaling Scheme

| Step | Bit Field | Value |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| Selects whether the data/strobe or data/clock signaling scheme is used. For the correct settings as a function of the image sensor class, see Section 8.2.3, ISS CSI2 PHY. This setting must be configured in the control module. | See Section 8.2.3, ISS CSI2 PHY. For the register and bit field, see Chapter 18, Control Module (CONTROL_CAMERA_RX register). | 0x0: Data/clock 0x1: Data/strobe |

8.2.4.4.6 ISS CCP2 Programming Select the Mode: MIPI CSI1 or CCP2

Table 8-59 lists the procedure to select MIPI CSI1 or CCP2 mode.

Table 8-59. ISS CCP2 Select MIPI CSI1 or CCP2 Mode

| Step | Bit Field | Value |
|----------------------------------------------------------------------------|-------------------|------------------------------------------------------------------------------------------------------------------------------------|
| Selects whether the CCP2 module works in MIPI CSI1 or CCP2-compatible mode | CCP2_CTRL[4] MODE | 0x0: Disables the CCP2-specific features (data/strobe, CRC, logical channels, RAW6, RAW7, and DPCM data formats) 0x1: CCP2 mode |

8.2.4.4.7 ISS CCP2 Programming Burst Settings

Table 8-60 lists the procedure to configure the burst settings.

Table 8-60. ISS CCP2 Configure Burst Settings

| Step | Bit Field | Value |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| The module can be forced to perform single 64-bit requests or bursts of 2x, 4x, 8x, and 16 x 64 bits. The module must always use 16 x 64. The FIFO size is 64 x 64 bits. | CCP2_CTRL[6:5] BURST CSI2_CTRL[16] BURST_SIZE_EXPAND | 0x0: Single request. 0x1: 2 x 64-bit bursts 0x2: 4 x 64-bit bursts 0x3: 8 x 64-bit bursts 0x4: 16 x 64-bit bursts (with burst expand) |
| Enable 128 bytes (recommended setting) of the DMA CSI2/CCP DMA engine to burst 128 bytes over the L3 interconnect. | CSI2_CTRL[16] BURST_SIZE_EXPAND | 0x0: Use the burst size defined in the BURST_SIZE bit field. 0x1: Allow generation of 16 x 64-bit bursts. |

8.2.4.4.8 ISS CCP2 Programming Debug Mode

[Table 8-61](#) lists the procedure to enable debug mode.

Table 8-61. ISS CCP2 Enable Debug Mode

| Step | Bit Field | Value |
|--------------------|--------------------------------------|-------|
| Enable debug mode. | CCP2_CTRL[13] DBG_EN | 0x1 |

- During debug mode, the input comes from the [CCP2_DBG](#) register, not from the CCP2 physical interface. The full CCP2 receiver function can be debugged in debug mode. Full 32-bit values must always be written to the [CCP2_DBG](#) register.
- The following bit has no effect during debug mode:
 - [CCP2_CTRL\[0\] IF_EN](#)
- The following examples apply to the [CCP2_DBG](#) register:
 - Synchronization codes: [CCP2_DBG](#) = 0xFF000000 (LSC) or 0xFF000001 (LEC) or 0xFF000002 (FSC) or 0xFF000003 (FEC)
 - To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891, 0x326, and 0x547, write [CCP2_DBG](#) = 0x01234567 followed by [CCP2_DBG](#) = 0x89abcdef and [CCP2_DBG](#) = 0x76543210.

NOTE: Each write to the [CCP2_DBG](#) register sends a full 32-bit word through the CCP2 receiver hardware. When 8- or 16-bit writes are performed to the register, the previous 32-bit value is merged with the newly written one. When the driver writes, for example, 0x01234567 followed by 0x0000 00FF from the MPU subsystem informs that only 8 bits are written), the CCP2 receiver pipeline gets 0x01234567 followed by 0x012345FF.

8.2.4.4.9 ISS CCP2 Programming Video Port

[Table 8-62](#) lists the procedure to configure the video port.

Table 8-62. ISS CCP2 Configure Video Port

| Step | Bit Field | Value |
|-------------------------------------------------------------------------------------------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Set the video port output frequency. It varies from ISS_FLCK down to ISS_FLCK/65,536 MHz. | CCP2_CTRL[31:15] FRACDIV | From 1 to 65,536 |
| Enable video port clock during vertical blanking periods or not. | CCP2_CTRL[9] VP_CLK_FORCE_ON | 0x0: The video port clock is gated during vertical blanking periods. 0x1: The video port clock is free-running during vertical blanking periods. |

Table 8-62. ISS CCP2 Configure Video Port (continued)

| Step | Bit Field | Value |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Controls whether the video-port output is the only output interface enabled and applies for all channels. When <code>CCP2_CTRL[11] VP_ONLY_EN = 0x1</code> , the data are output only to the video port; the interface master port is not used. The two parts of the frame (embedded data and pixel data) are output to the video port (instead of pixel data to the video port and embedded data to the interconnect). <ul style="list-style-type: none"> The video port outputs the embedded data defined by the <code>CCP2_LCx_STAT_START</code> and <code>CCP2_LCx_STAT_SIZE</code> registers without decompression. The video port outputs the pixel data defined by the <code>CCP2_LCx_DAT_START</code> and <code>CCP2_LCx_DAT_SIZE</code> registers. | <code>CCP2_CTRL[11] VP_ONLY_EN</code> | |
| Control the video port pixel clock polarity: (Recommended setting: rising edge) | <code>CCP2_CTRL[12] VP_CLK_POL</code> | <p>0x0: The CCP2 receiver writes the data on the video port on the pixel-clock falling edge. The module connected to the video port samples the data on the pixel clock rising edge.</p> <p>0x1: The CCP2 receiver writes the data on the video port on the pixel-clock rising edge. The module connected to the video port samples the data on the pixel clock falling edge. Figure 8-28 shows the settings for <code>CCP2_CTRL.VP_CLK_POL</code>.</p> |

[Figure 8-28](#) shows the settings for `CCP2_CTRL.VP_CLK_POL`.

8.2.4.4.10 ISS CCP2 Programming Logical Channels

The CCP2 receiver supports simultaneous logical channels. Each logical channel is controlled independently with its own set of registers. The four sets of registers are identical, but some reset values are different.

The same description applies to all four logical channels (LCx, where x = 0 to 3).

All the registers in this section can be modified at any time. However, the modifications apply only from the start of the following frame.

8.2.4.4.11 ISS CCP2 Programming Controls

[Table 8-63](#) lists the procedure to enable the logical channels.

Table 8-63. ISS CCP2 Enable Logical Channels

| Step | Bit Field | Value |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------|-------|
| Enable logical channels. It has no effect if CCP2_CTRL[4] MODE = 0x0 . By default, all logical channels except logical channel 0 are disabled. Only the pixel data of one logical channel can go to the video preprocessing hardware; the SOF and EOF lines are always sent to memory through the interconnect interface. | CCP2_LCx_CTRL[0] CHAN_EN | 0x1 |

8.2.4.4.12 ISS CCP2 Programming Region-of-Interest

[Table 8-64](#) lists the procedure to enable the region-of-interest.

Table 8-64. ISS CCP2 Enable Region-of-Interest

| Step | Bit Field | Value |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------|-------|
| Enables the region-of-interest feature (SOF lines, pixel data, and EOF lines): <ul style="list-style-type: none"> If enabled, register settings set the position and size of each region; all data not in a region of interest are ignored. If disabled, all data in the frame are output. CCP2_LCx_CTRL[1] REGION_EN is set to 0x0 for a JPEG bitstream. | CCP2_LCx_CTRL[1] REGION_EN | 0x1 |

8.2.4.4.13 ISS CCP2 Programming CRC

[Table 8-65](#) lists the procedure to enable the CRC.

Table 8-65. ISS CCP2 Enable the CRC

| Step | Bit Field | Value |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|-------|
| Enable the CRC. If the received checksum and the computed checksum do not match, an interrupt is triggered: the corresponding event is LCx_CRC_IRQ . Setting CCP2_LCx_CTRL[2] CRC_EN = 0x1 has no effect if CCP2_CTRL[4] MODE = 0x0 . | CCP2_LCx_CTRL[2] CRC_EN | 0x1 |

8.2.4.4.14 ISS CCP2 Programming Destination Format

Control the destination format:

- The CCP2 receiver reformats received data to store it in memory or to send it to the video preprocessing.
- The [CCP2_LCx_CTRL\[7:3\] FORMAT](#) bit field controls the destination-data format:
 - EXP8 = Data expansion to 8 bits, padding with zeros
 - EXP16 = Data expansion to 16 bits, padding with alpha or zeros. The [CCP2_CTRL\[15:8\] ALPHA](#) bit field can be used to set an alpha value. For RGB444 + EXP16:
 - `data_out [31:28] = ALPHA [3:0]`
 - `data_out [15:12] = ALPHA [3:0]`
 - EXP32 = Data expansion to 32 bits, padding with alpha. The [CCP2_CTRL\[15:8\] ALPHA](#) bit field can be used to set an alpha value. For RGB888 + EXP32: `data_out [31:24] = ALPHA [7:0]`
 - FSP = False synchronization protection code decoding. Applies only to JPEG8 data format.
 - VP = Output to video preprocessing is enabled.

8.2.4.4.15 ISS CCP2 Programming Frame Acquisition

Table 8-66 lists the procedure to acquire frames.

Table 8-66. ISS CCP2 Frame Acquisition

| Step | Bit Field | Value |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| Program the number of frames that the CCP2 receiver acquires. The value of COUNT is decremented after each frame received. | CCP2_LCx_CTRL [31:24] COUNT | 0: The counter is free-running (default value). 1255: Remaining frames to be acquired |
| Writes to the COUNT bit field are controlled by the COUNT_UNLOCK bit. | CCP2_LCx_CTRL [16] COUNT_UNLOCK | |
| Configures PING and PONG addresses | CCP2_LCx_DAT_PING_ADDR and CCP2_LCx_DAT_PONG_ADDR | |
| Indicates whether the PING address or PONG address was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in CCP2_CTRL [0] IF_EN, the pixel data are written in the PING buffer and CCP2_LCx_CTRL [17] PING_PONG = 0x1 (PONG). After the first FEC synchronization code is received, the pixel data are written in the PONG buffer and CCP2_LCx_CTRL [17] PING_PONG = 0x0 (PING). CCP2_LCx_CTRL [17] PING_PONG toggles after every FEC synchronization code. | CCP2_LCx_CTRL [17] PING_PONG | |

After the correct number of frames is received, acquisition is automatically disabled ([CCP2_LCx_CTRL](#)[0] CHAN_EN = 0x0) and the COUNT_IRQ interrupt is triggered. The programmer can re-enable the acquisition by resetting the [CCP2_LCx_CTRL](#)[0] CHAN_EN bit to 0x1.

8.2.4.4.16 ISS CCP2 Programming Synchronization Codes

The FSC, FEC, LSC, and LEC synchronization codes have default values given by the *SMIA CCP2 Specification v1.0*. Also, each logical channel is identified by a default identifier.

The [CCP2_LCx_CODE](#) register enables overwriting of the default values: [CCP2_LCx_CODE](#)[11:8] FSC, [CCP2_LCx_CODE](#)[15:12] FEC, [CCP2_LCx_CODE](#)[3:0] LSC, and [CCP2_LCx_CODE](#)[7:4] LEC overwrite the 4 LSBs of the 32-bit synchronization codes. The default values must not be modified.

8.2.4.4.17 ISS CCP2 Programming Status Data

The SOF and EOF status lines can be output to memory.

The SOF and EOF status lines always cover full lines. No register settings enable the setting of width.

The [CCP2_LCx_STAT_START](#) register enables the setting of the vertical start position of the SOF and EOF status lines. Because the SOF status line comes first in the CCP2 frame, [CCP2_LCx_STAT_START](#)[11:0] SOF = 0x0.

The [CCP2_LCx_STAT_SIZE](#) register enables the setting of the numbers of SOF and EOF status lines. If [CCP2_LCx_STAT_SIZE](#)[11:0] SOF = 0x0 and [CCP2_LCx_STAT_SIZE](#)[27:16] EOF = 0x0, no status data are output.

Figure 8-29 shows the SOF and EOF region settings. The SOF and EOF status lines and the pixel data must not overlap, but can be consecutive.

Figure 8-29. ISS CCP2 SOF and EOF Region Settings

The 32-bit destination addresses of the SOF status lines are set by the [CCP2_LCx_SOF_ADDR](#) register.

NOTE: The destination addresses of the SOF status lines must be aligned on a 32-byte boundary; the 5 LSBs of the address are ignored. The SOF lines are packed together at the destination address.

The 32-bit destination addresses of the EOF status lines are set by the [CCP2_LCx_EOF_ADDR](#) register.

NOTE: The destination addresses of the EOF status lines must be aligned on a 32-byte boundary; the 5 LSBs of the address are ignored. The EOF lines are packed together at the destination address.

NOTE: The CCP2 receiver does not modify the data in the SOF and EOF status lines. The data are received and written with no modifications.

8.2.4.4.18 ISS CCP2 Programming Pixel Data Region

Pixel data can be output to memory or to the video-preprocessing hardware.

The pixel data region covers full lines. The [CCP2_LCx_DAT_SIZE](#) register sets the horizontal size of the pixel region. The vertical size is expressed in lines.

The [CCP2_LCx_DAT_START](#) register enables the setting of the vertical start position of the pixel data. The vertical start position is expressed in lines.

Figure 8-30 shows the pixel region settings.

Figure 8-30. ISS CCP2 Pixel Data Region Settings

camss-502

The 32-bit destination addresses of the pixel data are set by the [CCP2_LCx_DAT_PING_ADDR](#) and [CCP2_LCx_DAT_PONG_ADDR](#) registers.

NOTE: The destination address must be aligned on a 32-byte boundary; the 5 LSBs of the address are ignored. The pixel data lines are packed together at the destination address.

It is possible to perform double-buffering (ping-ponging) at the destination by setting different addresses in the [CCP2_LCx_DAT_PING_ADDR](#) and [CCP2_LCx_DAT_PONG_ADDR](#) registers. It is possible to disable double-buffering by setting up the same address in both registers. The [CCP2_LCx_CTRL\[17\]](#) PING_PONG bit must be used by software to determine which address contains the latest frame.

A destination pitch controls the address jump between the address of the first pixel of the previous line and the address of the first pixel of the current line. The destination pitch is set in bytes with the [CCP2_LCx_DAT_OFST](#) register. It applies for [CCP2_LCx_DAT_PING_ADDR](#) and [CCP2_LCx_DAT_PONG_ADDR](#).

NOTE: The destination pitch must be a multiple of 32 bytes; the 5 LSBs of the address are ignored.

The destination data format is set with the [CCP2_LCx_CTRL\[7:2\]](#) FORMAT bit field.

For the PING frame:

- @Line0 = [CCP2_LCx_DAT_PING_ADDR](#)
- @Line1 = @Line0 + [CCP2_LCx_DAT_OFST](#)

- @Line2 = @Line1 + CCP2_LCx_DAT_OFST

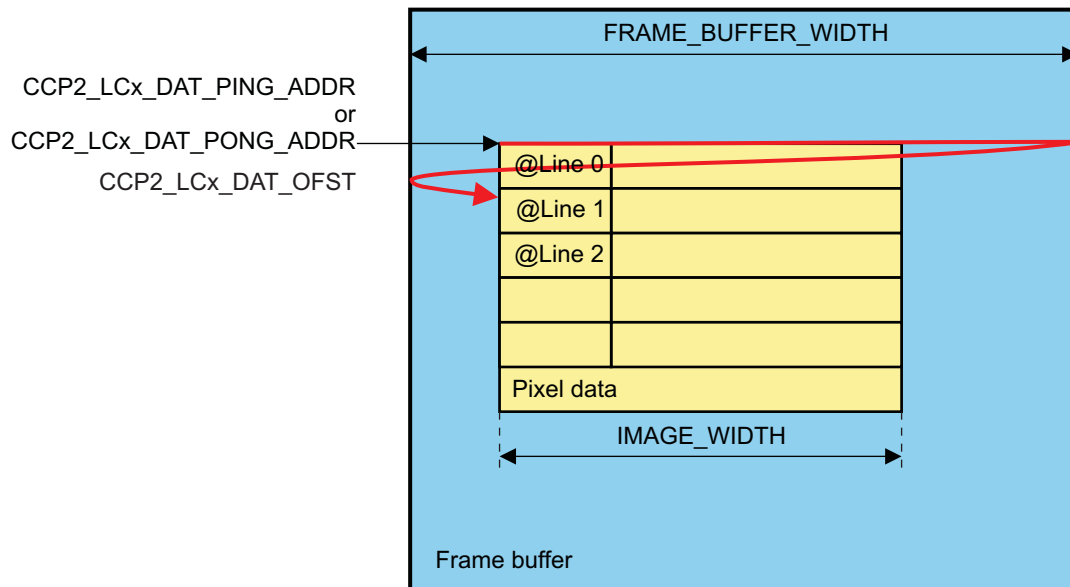

For the PONG frame:

- @Line0 = CCP2_LCx_DAT_PONG_ADDR
- @Line1 = @Line0 + CCP2_LCx_DAT_OFST
- @Line2 = @Line1 + CCP2_LCx_DAT_OFST

When CCP2_LCx_DAT_OFST = 0x0, the lines are written contiguously in memory. The destination pitch enables 2D transfers; it is required to write the pixel data directly in the frame buffer, for instance.

In such cases, CCP2_LCx_DAT_OFST = FRAME_BUFFER_WIDTH. Figure 8-31 shows the pixel data destination settings.

Figure 8-31. ISS CCP2 Pixel Data Destination Settings

camss-503

8.2.4.4.19 ISS CCP2 Programming Memory Read Channel

8.2.4.4.19.1 ISS CCP2 Write Data From Sensor to Memory

Data can be captured from the sensor using any logical channel. To keep the native data format, the channel format must be set to YUV4:2:2 little-endian format.

8.2.4.4.19.2 ISS CCP2 Read Data From Memory

Table 8-67 lists the procedure to configure read data from memory.

Table 8-67. ISS CCP2 Configure Read Data From Memory

| Step | Bit Field | Value |
|------------------------------------------------------------------------------------------------------|-------------------------------|-------|
| Disable all logical channels. | CCP2_CTRL[0] IF_EN | 0x0 |
| Wait until disabling of the physical interface is effective before enabling the memory read channel. | CCP2_CTRL[3] FRAME | 0x1 |
| Configure the burst size. The recommended value for best performance is 0x4 (16 x 64-bit burst). | CCP2_LCM_CTRL[7:5] BURST_SIZE | – |

Table 8-67. ISS CCP2 Configure Read Data From Memory (continued)

| Step | Bit Field | Value |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------|
| Configure the source data format, location, and framing. In addition to the CCP2_LCM_HSIZE[11:0] SKIP and CCP2_LCM_HSIZE[27:16] COUNT bit fields, firmware must specify the amount of data to be fetched from memory. This value is set in 64-bit word steps and must be a multiple of 32 bytes (four words of 64 bits). The value is computed with the following formula: $\text{HWORDS} = 4 \times \text{ceil}((\text{SKIP} + \text{COUNT}) \times \text{bits_per_pixel}) / (8 \times 32)$ (3) The CCP2_LCM_SRC_ADDR and CCP2_LCM_SRC_OFST registers must be aligned on 32-byte boundaries for correct operation. For best performance, both registers must be aligned on 256-byte boundaries. See the example following this table. | CCP2_LCM_CTRL , CCP2_LCM_HSIZE , CCP2_LCM_VSIZE , CCP2_LCM_PREFETCH , CCP2_LCM_SRC_ADDR , CCP2_LCM_SRC_OFST | |
| Select destination. | CCP2_LCM_CTRL[2] DST_PORT | 0x0: Video port 0x1: Memory |
| If destination = video port, configure clock frequency and its gating during frame blanking periods. | CCP2_CTRL[31:15] FRACDIV, CCP2_CTRL[9] VP_CLK_FORCE_ON | |
| If needed, configure READ_THROTTLE to reduce the bandwidth in memory-to-memory operation to prevent system overload. It has no effect when data are sent to the video port (controlled by video port clock in this case). | CCP2_LCM_CTRL[4:3] READ_THROTTLE | |
| If the memory write port is used, the destination format and address must be configured. | CCP2_LCM_DST_ADDR , CCP2_LCM_DST_OFST | |
| Enable memory read channel. After processing a full frame, this bit is automatically cleared by hardware and an EOF event is triggered. | CCP2_LCM_CTRL[0] CHAN_EN | 0x1 |

Example:

- [CCP2_LCM_CTRL\[7:5\]](#) BURST_SIZE is set to 16 × 64 bits
- [CCP2_LCM_HSIZE\[11:0\]](#) SKIP = 0
- [CCP2_LCM_HSIZE\[27:16\]](#) COUNT = 1000
- [CCP2_LCM_CTRL\[23\]](#) SRC_PACK = YES
- [CCP2_LCM_CTRL\[18:16\]](#) SRC_FORMAT = RAW6
- [CCP2_LCM_PREFETCH\[15:3\]](#) HWORDS = 96 (>=94)
 Setting the size to 94 produces the following burst sequence: 16, 16, 16, 16, 16, 8, and 4 (7 interconnect requests). However, when it is set to 96, the burst sequence is 6 × 16 (6 interconnect requests).

| Bits | Field Name | Description | Type | Reset |
|-------|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------|
| 31:15 | FRACDIV | Fractional clock divider control for the video port. The mean video port clock is VPBASECLOCK * FRACDIV/65536. Valid range: 1-65536 | RW | 0x10000 |
| 14 | POSTED | Selects between posted and non posted writes. 0x0: Non posted 0x1: Posted | RW | 0 |
| 13 | DBG_EN | Enables the debug mode. 0x0: Disable 0x1: Enable | RW | 0 |
| 12 | VP_CLK_POL | VP clock polarity 0x0: The CCP2 receiver writes the data on the VP on the L3 falling edge before the next falling PCLK edge. 0x1: The CCP2 receiver writes the data on the VP on the L3 rising edge before the next rising PCLK edge. | RW | 0 |
| 11 | VP_ONLY_EN | VP only enable. 0x0: The VP is enabled and the OCP master port are enabled. 0x1: The VP is enabled and the OCP master port is disabled. The embedded data and pixel data are output on the VP. | RW | 0 |
| 10 | RESERVED | Read returns reset value | RW | 0 |
| 9 | VP_CLK_FORCE_ON | Controls VP_PCLK gating during frame blanking periods. 0x0: The VP_PCLK is gated during vertical blanking periods. 0x1: The VP_PCLK is free-running during vertical blanking periods. | RW | 0 |
| 8 | RESERVED | | R | 0 |
| 7:5 | BURST | Forces the write burst size used by the module. The write burst size shall never exceed the output FIFO size. The output FIFO size can be read with the CCP2_GNQ.FIFODEPTH bit field. 0x0: 1x 64-bit burst = single request. 0x1: 2x 64-bit bursts. 0x3: 8x 64-bit bursts. 0x4: 16x 64-bit bursts. 0x2: 4x 64-bit bursts. | RW | 0x0 |
| 4 | MODE | Selects the receiver operating mode. This bit is only writable when the CCP2MODE input is 1. 0x0: MIPI CSI1 compatible mode. When this bit is set all CCP2 settings are ignored. If the settings are not set correctly to MIPI CSI1 values, the behavior of the receiver is unpredictable. 0x1: CCP2 compatible mode | RW | 0 |
| 3 | FRAME | Set the modality in which IF_EN works. 0x0: When software writes IF_EN = 0 the interface is disabled immediately. 0x1: When software writes IF_EN = 0 the interface is disabled after the next FEC sync code. | RW | 0 |
| 2 | RESERVED | Read returns reset value | RW | 0 |
| 1 | RESERVED | Read returns reset value | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 0 | IF_EN | <p>Enables the physical interface to the module.</p> <p>0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled on the next FEC sync code. If FRAME=1, it is advised to disable the logical channels first (CCP2_LCX_CTRL.CHAN_EN=0) before writing IF_EN=0.</p> <p>0x1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing 1 to this register when the current value is 0 has the effect to clear the output FIFO. The pixel data of the following frame will be written in the PING buffer, that is, the CCP2_LCX_CTRL.PING_PONG bits are reset to 1 as well.</p> | RW | 0 |

| Physical Address | 0x5200 1C78 + (x * 0x30) | Instance | ISS_CCP2 |
| Description | <p>DATA MEM ADDRESS OFFSET REGISTER - LOG CHAN 0</p> <p>This register sets the offset, which is applied on the destination address after each line is written to memory. This register applies for both CCP2_LC0_DAT_PING_ADDR and CCP2_LC0_DAT_PONG_ADDR.</p> <p>For example, it enables to perform 2D data transfers of the pixel data into a frame buffer. In such case, the pixel data and frame buffer data shall have the same data format.</p> <p>The 5 LSBs are ignored: the offset shall be a multiple of 32 bytes.</p> <p>Only full 64-bits words are written to memory at the end of lines.</p> <p>This register is shadowed: modifications are taken into account after the next FSC sync code.</p> | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31 | DST_PACK | <p>Data is packed before it is send to memory.</p> <p>Applies to RAW6, RAW7, RAW10, and RAW12 only.</p> <p>0x0: Disabled</p> <p>0x1: Enabled</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 30 | DST_DPCM_PRED | Selects the DPCM predictor to be used for the RAW6+DPCM10 and RAW7+DPCM10 data formats. The RAW8+DPCM10 data format always use the simple predictor. 0x0: The advanced predictor is used 0x1: The simple predictor is used. | RW | 0 |
| 29:28 | DST_COMPR | Enables data compression of data sent to memory 0x0: No compression 0x1: A-Law compression RAW10 -> RAW8 A-Law when DST_FORMAT=RAW8 other destination formats are invalid. 0x2: DPCM compression RAW10 -> RAW6 DPCM when DST_FORMAT=RAW6 RAW10 -> RAW7 DPCM when DST_FORMAT=RAW7 RAW10 -> RAW8 DPCM when DST_FORMAT=RAW8 other destination formats are invalid. | RW | 0x0 |
| 27 | RESERVED | | R | 0 |
| 26:24 | DST_FORMAT | Output format selection. Not every combination between input and output formats are possible. 0x6: RAW16 0x1: RAW7 0x0: RAW6 0x2: RAW8 0x4: RAW12 0x5: RAW14 0x3: RAW10 | RW | 0x0 |
| 23 | SRC_PACK | Data stored in memory is packed and must be unpacked. 0x0: Disabled 0x1: Enabled | RW | 0 |
| 22 | SRC_DPCM_PRED | Selects the DPCM predictor to be used for the RAW6+DPCM10, RAW7+DPCM10 and RAW8+DPCM12 data formats. The RAW8+DPCM10 and RAW6 + DPCM12 data format always use the simple predictor. 0x0: The advanced predictor is used 0x1: The simple predictor is used. | RW | 0 |
| 21:20 | SRC_DECOMPR | Enable decompression of incoming data 0x0: No decompression 0x1: A-Law decompression RAW8 A-Law -> RAW10 when SRC_FORMAT=RAW8 other source formats are invalid. 0x3: DPCM decompression RAW6 DPCM -> RAW12 when SRC_FORMAT=RAW6 RAW8 DPCM -> RAW12 when SRC_FORMAT=RAW8 other source formats are invalid. 0x2: DPCM decompression RAW6 DPCM -> RAW10 when SRC_FORMAT=RAW6 RAW7 DPCM -> RAW10 when SRC_FORMAT=RAW7 RAW8 DPCM -> RAW10 when SRC_FORMAT=RAW8 other source formats are invalid. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 19:16 | SRC_FORMAT | Data format of the data stored in memory. As there is no header embedded in the data sent to memory the user is responsible of choosing the adequate format. 0x6: RAW16 0x1: RAW7 0xA: Reserved 0x7: Reserved 0xD: Reserved 0x0: RAW6 0x2: RAW8 0x8: Reserved 0x9: Reserved 0xB: Reserved 0x4: RAW12 0x5: RAW14 0xF: Reserved 0xC: Reserved 0x3: RAW10 0xE: Reserved | RW | 0x0 |
| 15:8 | RESERVED | | R | 0x00 |
| 7:5 | BURST_SIZE | Defines the burst size of the master read port 0x0: 1x 64-bit burst = single request. 0x1: 2x 64-bit bursts. 0x3: 8x 64-bit bursts. 0x4: 16x 64-bit bursts. 0x2: 4x 64-bit bursts. | RW | 0x0 |
| 4:3 | READ_THROTTLE | Limit maximum data read speed for memory to memory operation 0x0: Full speed. Throughput is limited by internal processing capabilities. 0x1: 1/2 speed 0x3: 1/8 speed 0x2: 1/4 speed | RW | 0x0 |
| 2 | DST_PORT | Select the destination port 0x0: Data is send to video port, it is always send without compression or packing. The DST_COMPR, DST_DPCM_PRED, DST_PACK, CCP2_LCM_DST_WRITE, and CCP2_LCM_DST_OFST registers have no effect. 0x1: Data is send to memory. | RW | 0 |
| 1 | RESERVED | | R | 0 |
| 0 | CHAN_EN | Enables the read from memory channel. Before enabling the memory read channel software shall: - disable the physical interface using the IF_EN bit - wait until disabling of the physical interface is effective (depends on the FRAME bit) Read from memory starts as soon as this bit is set, therefore all CCP2_LCM_x registers must be configured correctly before. This bit is cleared by hardware at the end of the frame. 0x0: Disabled 0x1: Enabled | RW | 0 |

8.2.5 ISS CSI2

8.2.5.1 ISS CSI2 Environment

8.2.5.1.1 ISS CSI2 Protocol and Data Format

The CSI2 supports MIPI CSI2 multiple data type formats. This section describes MIPI CSI2 protocol and data formats. The CSI2 is compatible with the *MIPI CSI2 Specification v1.0-01-00 r0.03*. [Table 8-136](#) lists the MIPI CSI2 supported by CSI2 formats in addition to JPEG8. Shading in the primary and secondary MIPI CSI2-defined formats indicates special format extensions of the CSI2 receiver.

[Table 8-136](#) summarizes the pixel formats supported by the CSI2 receiver interface.

Table 8-136. ISS CSI2 Pixel Format Modes

| CSI2_CTX_CT RL2_i[9:0] Format | CSI2 Data Format | Bits per Pixel (BPP) | Data Size Increases in Memory | 2D Mode Availability ⁽¹⁾ | Comments |

⁽¹⁾ If 2D mode is available, there are no supplementary constraints on data width. 2D mode does not apply when sending to the video port (VP).

For more information about how the data formats are transmitted and how the data are stored in memory, see [Section 8.2.5.1.1.4, CSI2 Operating Modes](#).

NOTE: The VP formats are not included in [Table 8-136](#), because they are not sent to memory; instead they are sent to the ISP for further processing.

NOTE: Data written by CSI2 can be read back by the CCP2 read channel. CCP2 can get data from a sensor or memory. For more information about supported memory operations, see [Table 8-52](#).

8.2.5.1.1.1 ISS CSI2 Physical Layer

The CSI2-A/CSI2-B receivers are tightly connected to a PHY layer (for more information about the PHY, see [Section 8.2.3, ISS CSI2 PHY](#)). [Table 8-137](#) lists the CSI2-A receiver I/O, and [Table 8-138](#) lists the CSI2-B I/O. The CSI2_RECEIVER provides access to the complex I/O configuration from the [CSI2_COMPLEXIO_CFG](#) register.

Table 8-137. ISS CSI2-A I/O Description

| Signal Name | | I/O ⁽¹⁾ | Description |
|-------------|------------------------|--------------------|-------------------------|
| csi2a_dx0 | lane 0 (position 1) | I | Serial data/clock input |
| csi2a_dy0 | | | |
| csi2a_dx1 | lane 1 (position 2) | I | Serial data/clock input |
| csi2a_dy1 | | | |
| csi2a_dx2 | lane 2 (position 3) | I | Serial data/clock input |
| csi2a_dy2 | | | |
| csi2a_dx3 | lane 3 (position 4) | I | Serial data/clock input |
| csi2a_dy3 | | | |
| csi2a_dx4 | lane 4 (position 5) | I | Serial data input only |
| csi2a_dy4 | | | |

⁽¹⁾ I = Input

Table 8-138. ISS CSI2-B I/O Description

| Signal Name | | I/O ⁽¹⁾ | Description |
|-------------|------------------------|--------------------|-------------------------|
| csi2b_dx0 | lane 0 (position 1) | I | Serial data/clock input |
| csi2b_dy0 | | | |
| csi2b_dx1 | lane 1 (position 2) | I | Serial data/clock input |
| csi2b_dy1 | | | |

⁽¹⁾ I = Input

NOTE: The serial lane can be used as clock lane or data lane (excluding lane 4 on the CSI2-A I/O). The MIPI CSI2 protocol requires one clock lane (others are data lane or unused lane).

Lanes support the two operating modes:

- HS mode: High-speed transmit mode
- Off mode: Lane is off.

8.2.5.1.1.2 ISS CSI2 Lane Merger

The layer consists of lane merger logic to merge the incoming serial stream into a byte stream. The lane merger can merge up to four lanes (CSI2-A) into a single byte stream. The bits are sent with the LSB first. The order of the lanes at the CSI2-A, CSI2-B receiver core depends on the lane configuration. The merger is not used for a single lane.

The number of lanes and their configuration can be changed only in ULPM or when all data lanes are in off mode.

Figure 8-32 to Figure 8-35 show the byte position into each serial link for one to four data lane configurations. The byte stream always starts from lane 1. It finishes on one of the lanes, depending on the number of bytes to receive and the number of lanes.

Figure 8-32. ISS CSI2 One Data-Lane Configuration

Figure 8-33. ISS CSI2 Two Data-Lane Merger Configuration

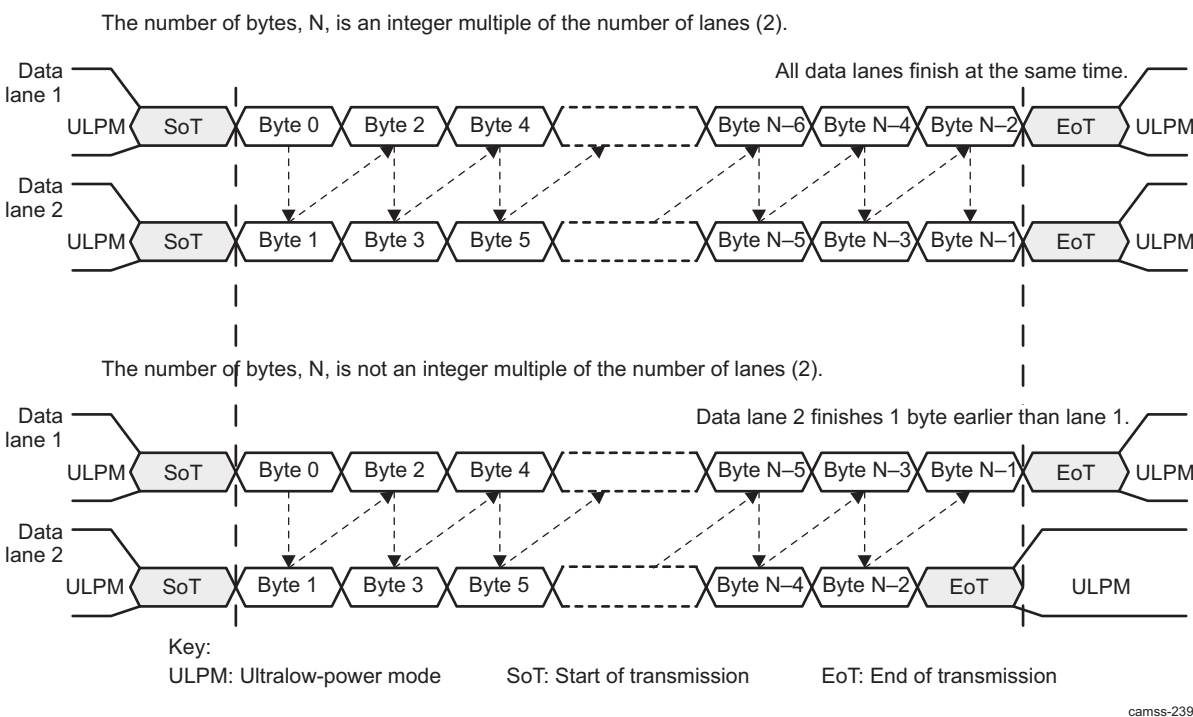

Figure 8-35. ISS CSI2 Four Data-Lane Merger Configuration

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes:

Number of bytes, N, transmitted is not an integer multiple of the number of data lanes:

camss-258

8.2.5.1.1.3 ISS CSI2 Protocol Layer

The low-level protocol (LLP) is a byte-oriented protocol from the lane merger layer. It supports short and long packet formats.

The CSI2 protocol layer defines how image-sensor data is transported onto the physical layer.

The feature set of the protocol layer implemented by the CSI2 receiver is:

- Transport of arbitrary data (payload-independent)
- 8-bit word size
- Support for up to four interleaved virtual channels on the same link
- Special packets for frame-start, frame-end, line-start, and line-end information
- Descriptor for the type, pixel depth, and format of application-specific payload data
- Error-correction code (ECC) for 1-bit error correction or 2-bit error detection in the header
- 16-bit checksum code for payload error detection

Figure 8-36 shows the CSI2 protocol layer with short and long packets.

Figure 8-36. ISS CSI2 Protocol Layer With Short and Long Packets

camss-241

Two packets are always separated from each other with a sequence of ET, ULPM, and ST.

8.2.5.1.1.3.1 ISS CSI2 Short Packet

A short packet is identified by data types 0x00 to 0x0F. A short packet can be used for frame or line synchronization or for generic data. Figure 8-37 shows the structure of a short packet.

Figure 8-37. ISS CSI2 Short Packet Structure

camss-242

For frame-synchronization data types, the short packet data field is the frame number. For line-synchronization data types, the short packet data field is the line number. For generic short packet data types, the content of the short packet data field is user-defined.

The 16-bit frame number, when used, is always nonzero to distinguish it from the use case where the frame number is inoperative and remains set to 0. The behavior of the 16-bit frame number is one of the following:

- The frame number is always 0 and is inoperative.
- The frame number increments by 1 for every FS packet within the same virtual channel and is periodically reset to 1 (1, 2, 1, 2, 1, 2, 1, 2 or 1, 2, 3, 4, 1, 2, 3, 4).

For LSC and LEC synchronization packets, the short packet data field contains a 16-bit line number. This line number is the same for the LS and LE packets corresponding to a given line. Line numbers are logical line numbers and do not necessarily equal physical line numbers. The 16-bit line number, when used, is always nonzero to distinguish it from the use case where the line number is inoperative and remains set to 0.

The behavior of the 16-bit line number is one of the following:

- The line number is always 0 and is inoperative.
- The line number increments by 1 for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to 1 for the first LS packet after an FS packet. The intended use is for progressive scan (noninterlaced) video data streams. The line number must be a nonzero value.
- The line number increments by the same arbitrary step value greater than 1 for every LS packet within the same virtual channel and the same data type. The line number is periodically reset to a nonzero

arbitrary start value for the first LS packet after an FS packet. The arbitrary start value can be different between successive frames. The intended use is for interlaced video data streams.

The ECC byte allows single-bit errors to be corrected and 2-bit errors to be detected in the short packet.

Short packets apply to all contexts using the same virtual channel ID (up to eight contexts support eight dedicated configurations of virtual channel ID and data types). The data type associated with the context is not used to distinguish which context is used when receiving short packets.

8.2.5.1.1.3.2 ISS CSI2 Long Packet

A long packet is identified by data types 0x10 to 0x37. A long packet consists of three elements:

- A 32-bit packet header (PH)
- An application-specific data payload with a variable number of 8-bit data words
- A 16-bit packet footer (PF)

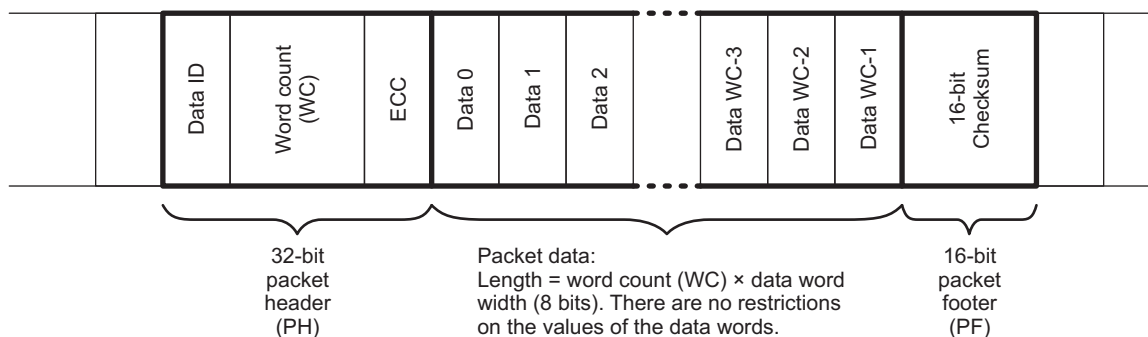

The packet header is composed of three elements:

- An 8-bit data identifier
- A 16-bit word count field
- An 8-bit ECC

The packet footer has one element, a 16-bit checksum.

Figure 8-38 and Table 8-139 show the structure of a long packet.

Figure 8-38. ISS CSI2 Long Packet Structure

camss-243

Table 8-139. ISS CSI2 Long Packet Structure Description

| Packet Part | Field Name | Size (Bits) | Description |
|-------------|------------|-------------|--------------------------------------------------------------------------------------|
| Header | Data ID | 8 | Contains the virtual channel identifier and the data-type information |
| | Word count | 16 | Number of data words in the packet data. A word is 8 bits. |
| | ECC | 8 | ECC for data ID and WC field. Allows 1-bit error recovery and 2-bit error detection. |
| Data | Data | WC-8 | Application-specific payload (WC words of 8 bits) |
| Footer | Checksum | 16 | 16-bit CRC for packet data |

There are no restrictions on the size of the packet data, but each data format can impose additional restrictions on the length of the payload data (for example, a multiple of 4 bytes).

8.2.5.1.1.3.3 ISS CSI2 Data Identifier

The data identifier byte contains the virtual channel (VC) value and the data-type (DT) value, as shown in Figure 8-39. The VC value is in the 2 MSBs of the data identifier byte. The DT value is in the 6 LSBs of the data identifier byte.

Figure 8-39 shows the data identifier structure.

Figure 8-39. ISS CSI2 Data Identifier Structure

camss-244

Virtual Channel

The CSI2 protocol layer transports virtual channels. Virtual channels are built of frames. A frame can comprise embedded data and image-sensor data. Two contexts are used to send the two types of data separately. Each frame is identified by unique mandatory synchronization codes: frame start and frame end. Line start and line end synchronization codes are optional for the transmitter. A set of registers is associated with each context defined by the virtual channel ID and the data type. Figure 8-40 shows a virtual channel.

Figure 8-40. ISS CSI2 Virtual Channel

camss-245

Pixel Formats

8.2.5.1.1.3.4 ISS CSI2 Synchronization Codes

Data reception from the image-sensor module uses four synchronization codes embedded in the serial bitstream:

- FSC: Identifies the start of a new frame
- LSC: Identifies the start of a new line; received for every line
- LEC: Identifies the end of a line; received for every line
- FEC: Identifies the end of the last line and the end of the current frame

Table 8-140 summarizes the synchronization code values.

Table 8-140. ISS CSI2 Synchronization Codes

| Synchronization Code | Value | Comments |
|----------------------|------------|-----------|
| FSC | 0x0 | Mandatory |
| FEC | 0x1 | Mandatory |
| LSC | 0x2 | Optional |
| LEC | 0x3 | Optional |
| Reserved | 0x4 to 0x7 | Not used |

8.2.5.1.1.3.5 ISS CSI2 Generic Short Packet Codes

When the synchronization code value is from 0x8 to 0xF, the short packet is called a generic short packet. Short packets are not processed by the camera interface hardware. A generic short packet is stored in a register without the ECC and an interrupt can be generated. Therefore, generic short packets must be handled by software.

8.2.5.1.1.3.6 ISS CSI2 Generic Long Packet Codes

The code value 0x10 indicates null packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x11 indicates blanking packets, which can be received at any time. They are discarded by the protocol engine.

The code value 0x12 indicates embedded 8-bit nonimage data typically used for JPEG.

Code values from 0x13 to 0x17 are reserved.

8.2.5.1.1.3.7 ISS CSI2 Frame Structure

Each frame consists of short packets to indicate SOF and EOF. Optional short packets for start of line and end of line can be sent by the image sensor.

Some information before and after the picture data can be sent as SOF and EOF information by the image sensor to the memory through the L3 port.

For each frame, the pixel data (arbitrary data or user-defined byte data) are valid only after an SOF short packet. If the data are invalid, they are discarded by the protocol engine.

A frame contains embedded data and image-sensor data. [Figure 8-41](#) shows where the embedded data and image-sensor data are in the frame. The frame is scanned in raster order starting from the top-left corner, as shown in [Figure 8-41](#) and [Figure 8-42](#). The following definitions for a frame apply:

- Zero or more SOF status lines (SOF lines) can be embedded at the beginning of a CSI2 frame.
- The image embedded data is carried using separate data types and virtual channels (see [Section 8.2.4.1.1, ISS CCP2 Protocol and Data Formats](#), and [Section 8.2.5.3.3.4, ISS CSI2 Virtual Channel and Context](#)).
- Zero or more EOF status lines (EOF lines) can be embedded at the end of a CSI2 frame.
- The SOF lines, pixel data, and EOF lines do not overlap.

The CSI2 receiver does not use the information in the status lines. However, it extracts it and stores it in memory for use by software.

Because the data types are different, the data is carried using separate data types called virtual channels. Those must be mapped to the adequate context. The CSI2 receiver uses a different context for embedded data and image-sensor data. See [Section 8.2.5.3.3.4, ISS CSI2 Virtual Channel and Context](#).

Embedded data is supported as a context by the CSI2 receiver; therefore, there is no specific hardware support for embedded data.

camss-247

The period between the LEC and the new LSC is the line blanking period. The time between the FEC and the new FSC is the frame blanking period. The receiver works with the line blanking period set to 0. The image data is stored in memory by selecting one of the various operating modes. [Section 8.2.5.1.1.4](#) explains storing image data frames into memory.

8.2.5.1.1.4 ISS CSI2 Operating Modes**8.2.5.1.1.4.1 ISS CSI2 YUV Operating Modes****8.2.5.1.1.4.1.1 ISS CSI2 YUV4:2:0 8-Bit**

YUV4:2:0 8-bit data can be stored to memory in little-endian and big-endian format. To set the endianness for YUV4:2:0 use the [CSI2_CTRL\[4\]](#) ENDIANNESSESS bit. The line length sent through the CSI2 physical protocol is a multiple of 16 bits for odd lines and 32 bits for even lines.

For correct pixel reconstruction, the line length must be a multiple of 32 bits and the number of lines must be even. Figure 8-43 shows the storage format for YUV4:2:0 8-bit data. It is shown as little endian. If the data format is big endian, the figure changes accordingly. Set the `CSI2_CTX_CTRL2_j[9:0]` FORMAT bit field to 0x18 to select YUV4:2:0 8-bit mode. Even and odd lines do not have the same length. Offset must be set accordingly with the `CSI2_CTX_DAT_OFST_j[16:5]` OFST bit field; for example, if the offset is 0, the data is written in a contiguous way (bit-to-bit of odd and even lines). If the data has an offset, set the destination offset between the first pixel of the previous line and the first pixel of the current line being written to memory.

8.2.5.1.1.4.1.5 Camera ISP CSI2 Byte Swap

The CSI2 receiver incorporates a byte-swapping function. Software can optionally enable byte-swapping of the payload data by setting the CSI2_CTLx_CTRL1[31] BYTESWAP bit. This feature must be used only when the amount of payload data per packet is a multiple of 16 bits. The byte-swapping is performed before pixel reconstruction.

8.2.5.1.1.4.5 ISS CSI2 Generic Format

The CSI2 receiver supports a generic format to send data to memory and/or the video port. The generic mode is entered by setting the `CSI2_CTX_CTRL1_i[30]` GENERIC bit. The `CSI2_CTX_CTRL2_i[9:0]` FORMAT bit field defines how the data stream is decoded. When generic mode is enabled (GENERIC = 1), the MIPI data type code is ignored and data is decoded using the FORMAT bit. Whatever the MIPI data type code, it is ignored (the data stream is processed even if the FORMAT bit does not match the MIPI data type code.) When generic mode is not used (GENERIC = 0), the data stream is processed only when the MIPI data type code matches the FORMAT setting of the enabled context. If not matched, the data stream is not processed by the CSI2 engine. Only the virtual channel information is used to map a received data stream to a context. Software must ensure that a MIPI virtual channel used in generic mode is mapped only to a single context.

[Figure 8-63](#) shows the ISS CSI2 generic format.

8.2.5.2 ISS CSI2 Integration

Figure 8-64 is an overview of the integration of the CSI2-A/CSI2-B interface in the device. The figure is the top-level block diagram of the CSI2-A/CSI2-B receiver. The CSI2-A/CSI2-B receiver receives the serial data coming from a CSI2 compatible image sensor, converts it to parallel data, extracts the logical channels, detects and extracts the synchronization codes, reformats the data, and outputs it through the video port or the ISS interconnect interface.

Figure 8-64. ISS CSI2-A/CSI2-B Integration

camss-352b

The CSI2-A/CSI2-B receiver can send data directly to system memory using the master port or send it to the camera ISP using the video port.

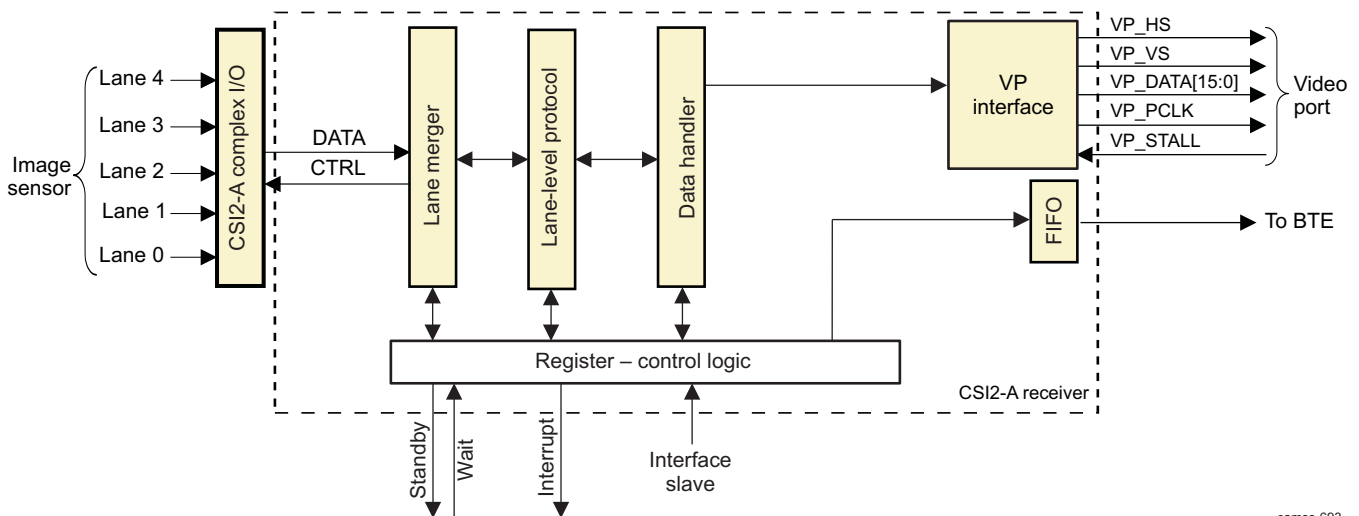

For power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

8.2.5.3 ISS CSI2 Functional Description

8.2.5.3.1 ISS CSI2 Overview

Figure 8-65 is the CSI2-A receiver block diagram (it assumes there are four CSI2 image sensor data lines). The only difference for CSI2-B is the number of lanes coming into the complex I/O. The CSI2 receiver receives the byte data coming from a CSI2 D-PHY receiver (up to four data pairs), converts it to byte stream, detects and corrects errors, extracts the virtual channel ID, detects and extracts the synchronization codes, reformats the data, and outputs it through the video port or the ISS interconnect interface. Data communication between CSI2 and ISP is done through the video port.

Figure 8-65. ISS CSI2-A Receiver Block Diagram

camss-693

8.2.5.3.2 ISS CSI2 Features

The CSI2 receiver is a master on the L3 interconnect for storing data in memory and a slave on the level 4 (L4) interconnect for register access.

The main features of the CSI2 receiver are:

- Transfer pixels and data received by the CSI2 PHY to the system memory or video processor
- Unidirectional data link
- Supports up to four data-configurable links in addition to the clock signaling (minimum of one data link and maximum of four depending on the speed)
- Data merger for two, three, or four data lane configurations
- Error detection and correction by the protocol engine
- DMA engine integrated with dedicated FIFO
- 1D and 2D addressing modes
- Up to eight contexts to support eight dedicated configurations of virtual channel ID and data types
- Ping-pong mechanism for double-buffering
- JPEG support for unknown length transfer (no extraction of the thumbnail)
- Supports all primary and secondary MIPI-defined formats (RGB, RAW, and YUV)
- Storage in progressive mode for interlaced stream (using line numbering)
- Conversion to the RGB formats
- Decompressions of the RAW formats
- RAW frame transcoding, including DPCM and A-Law compression
- Fully configurable interface of the complex PHY I/O: position of the clock and data and order of \pm differential signals for each pair

8.2.5.3.3 ISS CSI2 Functional Description

8.2.5.3.3.1 ISS CSI2 Physical Layer Lane Configuration

The CSI2 serial interface is a unidirectional differential serial interface with data/clock for the physical layer.

The maximum CSI2 receiver data transfer capacity is 1000 Mbps per data lane.

Data-clock signaling consists of two to five differential signal pairs: from one to four data lanes and one clock lane:

- The data signal carries the bit-serial data. The CSI2 transmitter in the image sensor sends the data in-quadrature with the dual-data rate (DDR) clock in HS mode; otherwise, the clock is extracted from the received data in LS mode. Data is transmitted byte-wise, LSB first. The CSI2 complex I/O receives the data and sends the byte stream to the CSI2 receiver.
- The clock signal carries the DDR clock signal.

Each physical lane can be a data or clock lane with a restriction to the fourth line, which can only be data (see [Section 8.2.3.1, ISS CSI2 PHY Overview](#)). The clock/data lane must be configured before transmission to indicate the byte order, while merging the received bytes into a byte stream shows the reachable speed per data lane function of data lane numbers.

Lanes are configured through the [CSI2_COMPLEXIO_CFG](#) registers for CSI2-A and CSI2-B PHY, respectively. The [CSI2_COMPLEXIO_CFG\[2:0\] CLOCK_POSITION](#) bit field and the [CSI2_COMPLEXIO_CFG\[3\] CLOCK_POL](#) bit configure which lane transmits the clock and define its polarity. [DATAI_POSITION](#) and [DATAI_POL](#) configure the data lanes and their polarity, where *I* is the number of the data lane (*I* = 1 to 4). When the [DATAI_POSITION](#) field is set to 0, data lane *I* is not used.

CAUTION

Lane 4 (position 5) supports only data. [CLOCK_POSITION](#) must not be set at position 5.

8.2.5.3.3.2 ISS CSI2 ECC and Checksum Generation

The CSI2 receiver includes an ECC in the packet header and a checksum in the packet footer for long-packet transmission. These two fields can be used to detect and/or correct errors in the received packet.

8.2.5.3.3.2.1 ISS CSI2 ECC

To detect and correct transmission errors of the header of short and long packets, an 8-bit ECC is included in the header of packets (short and long packet).

The ECC concerns all the fields for a short packet (data ID and short-packet data field) and the packet header for a long packet (data ID and word count). The ECC can only correct one error. Additional errors cannot be repaired, but they are flagged.

The CSI2 receiver ECC is compared against the CSI2 transmitter ECC embedded in the bitstream. If the ECC does not match, an interrupt is triggered to the host central processing unit (CPU).

For long and short packets, the correction is always done if there is only one error per packet header.

An ECC error with or without correction can be reported at two levels, depending on the type of packet. [Table 8-142](#) describes the field in which events are logged. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_IRQENABLE](#) and [CSI2_CTX_IRQENABLE_i](#) registers to prevent event generation at a higher level.

Table 8-142. ISS CSI2 ECC Event Logging

| | Short Packet | Long Packet |
|--------------------|------------------------------------------------------------------------|---------------------------------------------------------------------------|
| With correction | Global CSI2_IRQSTATUS [12] ECC_CORRECTION_IRQ | Context CSI2_CTX_IRQSTATUS_i [8] ECC_CORRECTION_IRQ |
| Without correction | Global CSI2_IRQSTATUS [11] ECC_NO_CORRECTION_IRQ | Global CSI2_IRQSTATUS [11] ECC_NO_CORRECTION_IRQ |

The ECC check can be disabled (short and long packet) by setting the [CSI2_CTRL](#)[2] ECC_EN bit to 0. Setting the bit to 1 enables the ECC check.

8.2.5.3.3.2 ISS CSI2 Checksum

To detect errors in transmission of the payload of long packets, a 16-bit CRC checksum is computed on the payload of the long packets in the transmitter. This CRC is stored in the packet footer. A CRC is also computed in the CSI2 receiver. If the checksums do not match, an interrupt is triggered to the host CPU.

CRC errors are logged in the CS_IRQ field of the corresponding context register, [CSI2_CTX_IRQSTATUS_i](#). Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_CTX_IRQENABLE_i](#) register to prevent event generation at a higher level.

The CRC can be disabled for a specific context by setting the [CSI2_CTRL](#)[5] CS_EN bit to 0. Setting the bit to 1 enables the CRC.

8.2.5.3.3.3 ISS CSI2 Short Packet

There are two types of short packets in the CSI2 receiver:

- Synchronization short packet: Used by the protocol engine to synchronize frame and line (data ID from 0x0 to 0x7)
- Generic short packet: User-dependent; not treated by the protocol engine (data ID from 0x8 to 0xF)

When a generic short packet is received by the CSI2 receiver, the ECC check is performed if it is enabled. Then, the short packet is written in the [CSI2_SHORT_PACKET](#)[23:0] SHORT_PACKET bit field. The ECC field is deleted from the short packet. [Figure 8-66](#) shows the SHORT_PACKET bit field format.

Figure 8-66. ISS CSI2 SHORT_PACKET Bit Field Format

When a short packet is stored, an event is logged in the [CSI2_IRQSTATUS](#)[13] SHORT_PACKET_IRQ bit. Logging cannot be disabled, but users can set the corresponding bit in the [CSI2_IRQENABLE](#) register to prevent event generation at a higher level.

The application reads the [CSI2_SHORT_PACKET](#) register before the next short packet with a code from 0x8 to 0xF. There is a single register for capturing the generic short packet, because no data type in it is associated with context.

8.2.5.3.3.4 ISS CSI2 Virtual Channel and Context

The CSI2 protocol layer transports virtual channels. The virtual channels separate different data flows interleaved in the same data stream. Each virtual channel is identified by a unique channel identification number in the packet header. This channel identification number is encoded in the 2-bit code.

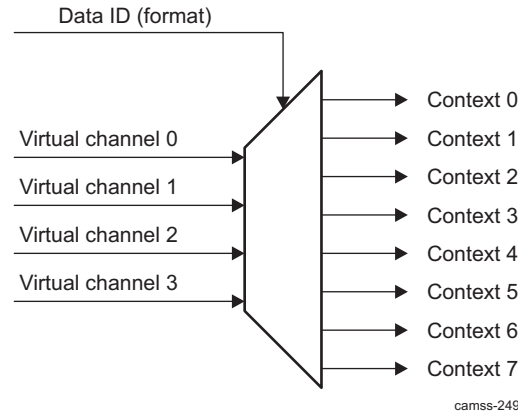

The CSI2 receiver monitors the channel identifier number and demultiplexes the interleaved data streams. The CSI2 receiver supports up to four concurrent virtual channels.

The CSI2 receiver supports eight contexts with their events to control the four possible virtual channels and the different data transmitted through them. A context is linked to a specific data type transported by a given virtual channel. The following bit fields permit configuration of a context:

- [CSI2_CTX_CTRL2_i\[12:11\]](#) VIRTUAL_ID: Configures the virtual ID linked to the current context
- [CSI2_CTX_CTRL2_i\[9:0\]](#) FORMAT: Configures the data format linked to the current context

Figure 8-67 shows the relationships between virtual channels and contexts.

Figure 8-67. ISS CSI2 Virtual Channel to Context

camss-249

Each context consists of eight registers: six registers to control the corresponding context and two to log and enable events from the context. All registers in a context can be modified at any time; however, modifications apply only from the start of the following frame.

A context can be enabled independently by setting the [CSI2_CTX_CTRL1_i\[0\]](#) CTX_EN bit to 1; setting this bit to 0 disables the corresponding context.

When acquiring frames on a context, users can write the number of frames to capture in the [CSI2_CTX_CTRL1_i\[15:8\]](#) COUNT bit field. Acceptable values are 0 to 255; 0 stands for infinite capture (no count). After each frame is acquired, the count value is decremented by 1. When the count value reaches 0, the [CSI2_CTX_IRQSTATUS_i\[6\]](#) FRAME_NUMBER_IRQ event is set and the CTX_EN bit is set to 0. To write a value in the COUNT bit field, the [CSI2_CTX_CTRL1_i\[4\]](#) COUNT_UNLOCK bit must be set to 1. If the value of the COUNT_UNLOCK bit is 0, a write in the COUNT bit field has no effect.

The [CSI2_CTX_CTRL3_i\[15:0\]](#) LINE_NUMBER bit field configures the generation of the [CSI2_CTX_IRQSTATUS_i\[7\]](#) LINE_NUMBER_IRQ event. The [CSI2_CTX_CTRL1_i\[1\]](#) LINE_MODULO bit configures how the LINE_NUMBER event is generated:

- 0: The event is generated one time by frame.
- 1: The event is generated modulo LINE_NUMBER (the event can be generated more than once in a frame).

During a frame capture, the [CSI2_CTX_CTRL2_i\[31:16\]](#) FRAME_NUMBER bit field shows the number that identifies the frame received.

8.2.5.3.3.5 ISS CSI2 DMA Engine

The CSI2 receiver integrates its own DMA engine with dedicated FIFO.

Global DMA configuration is common to the eight channels and is defined in the [CSI2_CTRL](#) register. Configuration of the ping-pong address and the offset between lines is specific for a given context; therefore, each context has its own DMA configuration registers.

The DMA engine supports:

- 1D addressing mode (no address line offset, [CSI2_CTX_DAT_OFST_i = 0](#))
- 2D addressing mode (address line offset different than 0, [CSI2_CTX_DAT_OFST_i = 0](#))

The burst size is defined in the [CSI2_CTRL\[6:5\] BURST_SIZE](#) bit field and the [CSI2_CTRL\[16\] BURST_SIZE_EXPAND](#) bit. The DMA uses the burst size or smaller sizes down to single open-core protocol (OCP) writes depending on the alignment at the end of lines. The DMA engine can handle burst requests. When the burst requests can be used, as soon as one burst of data is present in the FIFO, the DMA engine initiates a burst write. The burst size is defined in the [CSI2_CTRL\[6:5\] BURST_SIZE](#) bit field and the [CSI2_CTRL\[16\] BURST_SIZE_EXPAND](#) bit.

NOTE: Unless there are specific requirements, CSI2 (also applies to all other ISS initiators) must be configured to use only a burst size of 128 bytes and nonposted writes.

When single requests must be used, as soon as one element (the size depends on the data type and the post-processing: DPCM, EXT, etc.) is present in the FIFO, the DMA engine initiates a single write.

Interleave mode is dedicated by the CSI2 receiver only when the line numbers are received (short packets). The line number is used to calculate the start address of the line.

The DMA starts to write in memory using the [CSI2_CTX_DAT_PING_ADDR_i\[31:5\] ADDR](#) bit field for the first frame to be transferred, and then uses the [CSI2_CTX_DAT_PONG_ADDR_i\[31:5\] ADDR](#) bit field and the ping address alternately. Thus, the first frame uses the ping address, the second frame uses the pong address, the third frame uses the ping address, and so on.

The [CSI2_CTX_CTRL1_i\[3\] PING_PONG](#) status bit indicates whether the ping address ([CSI2_CTX_DAT_PING_ADDR_i](#)) or the pong address ([CSI2_CTX_DAT_PONG_ADDR_i](#)) was used to store the pixel data of the last frame. After reset or after a 0-to-1 edge transition in the [CSI2_CTRL\[0\] IF_EN](#) bit, the pixel data is written in the ping buffer and the [CSI2_CTX_CTRL1_i\[3\] PING_PONG](#) bit = PONG. When the number of FECs received equals the value programmed in the [CSI2_CTX_CTRL1_i\[23:16\] FEC_NUMBER](#) bit field, the pixel data are written in the pong buffer and [CSI2_CTX_CTRL1_i\[3\] PING_PONG](#) = PING. [CSI2_CTX_CTRL1_i\[3\] PING_PONG](#) toggles after the [CSI2_CTX_CTRL1_i\[23:16\] FEC_NUMBER](#) FEC sync code with the virtual channel ID defined is received in the [CSI2_CTX_CTRL2_i\[12:11\] VIRTUAL_ID](#) bit field.

The [CSI2_CTX_CTRL1_i\[23:16\] FEC_NUMBER](#) bit field must be set as follows:

- In progressive mode, set to 1.
- In interlaced mode, set to the number of interlaced frames to recreate a progressive image in the [PING_PONG](#) buffer.

8.2.5.3.3.5.1 ISS CSI2 Progressive Frame to Progressive Storage

After each line, a new start line address is computed, depending on the value of the [CSI2_CTX_DAT_OFST_i\[31:5\] OFST](#) bit field:

- If [OFST](#) = 0, the new line starts immediately after the last pixel (data are written contiguously in memory).
- Otherwise, the value of [OFST](#) sets the offset between the first pixel of the previous line and the first pixel of the current line in memory.

For the ping frame:

```
@Line0 = CSI2_CTX_DAT_PING_ADDR_i@Line1 = @Line0 + CSI2_CTX_DAT_OFST_i@Line2 = @Line1 + CSI2_CTX_DAT_OFST_i
```

For the pong frame:

```
@Line0 = CSI2_CTX_DAT_PONG_ADDR_i@Line1 = @Line0 + CSI2_CTX_DAT_OFST_i@Line2 = @Line1 + CSI2_CTX_DAT_OFST_i
```

8.2.5.3.3.5.2 ISS CSI2 Interlaced Frame to Progressive Storage

The mode is functional only when the line numbers are transmitted. It is automatically enabled without setting.

For the ping frame:

```
@LineX = CSI2_CTX_DAT_PING_ADDR_i + CSI2_CTX_DAT_OFST_i * Line_Number
```

For the pong frame:

$$\text{@LineX} = \text{CSI2_CTX_DAT_PONG_ADDR}_i + \text{CSI2_CTX_DAT_OFST}_i * \text{Line_Number}$$

Figure 8-68 shows how data are stored in memory regarding the DMA configuration.

Figure 8-68. ISS CSI2 Pixel Data Destination Setting in Progressive and Interlaced Mode

camss-250

The burst size is defined in the [CSI2_CTRL\[6:5\] BURST_SIZE](#) bit field for bursts up to 16 × 64 bits or the [CSI2_CTRL\[16\] BURST_SIZE_EXPAND](#) bit for 16 × 128-bit bursts. It can be changed only while the [CSI2_CTRL\[0\] IF_EN](#) bit is reset to 0. The recommended value is the [CSI2_CTRL\[16\] BURST_SIZE_EXPAND](#) bit set to 1, which defines a burst of 16 × 64 bits (the maximum value); otherwise, by default it is set to 8 × 64 bits. When the [BURST_SIZE_EXPAND](#) bit is set, the [BURST_SIZE](#) setting has no effect. The DMA uses nonposted writes by default. The [CSI2_CTRL\[13\] NON_POSTED_WRITE](#) bit must be set to 1 to match DMA default configuration. It can be changed only while the [CSI2_CTRL\[0\] IF_EN](#) bit is reset to 0.

8.2.5.3.3.6 ISS CSI2 MFLAG Mechanism and Arbitration

The MFLAG mechanism allows a dynamic increase of the priority of CSI2 real-time traffic, when required, based on the fullness of the CSI2 DMA read and write buffers. Programmable buffer thresholds indicate when the local MFLAG signal is generated. The MFLAG signal is then provided to the L3 interconnect for granting or prioritizing OCP requests. The out band CSI2 MFLAG signal is asynchronous to any on-going OCP transaction. The threshold corresponds to the fullness of DMA buffer, and is defined by the following threshold parameters:

- High threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes high (asserted). The value is set in the [CSI2_CTRL\[22:20\] MFLAG_LEVH](#) register.
- Low threshold – When the corresponding pipeline buffer reaches the programmed value, the associated local MFLAG signal goes low (deasserted). The value is set in the [CSI2_CTRL\[19:17\] MFLAG_LEVL](#) register.

8.2.5.3.3.7 ISS CSI2 Transcoding

Image transcoding is used mainly to reduce memory footprint and bandwidth when:

- The sensor does not support DPCM compression. In fact, A-Law and DPCM compressed pixels occupy only 6, 7, or 8 BPP of storage.
- Digital zoom is used
 - Data that is not going to be used by further processing does not need to be stored in system

memory.

- Pixels cannot be accessed from random locations in a DPCM-compressed frame. Transcoding avoids memory-to-memory processing of unused pixels.

Figure 8-69 shows the logical representation of the image transcoding operation.

- Data is extracted from the CSI2 stream by the protocol engine.
- It is DPCM decompressed if necessary. That is the case when the received stream is DPCM-compressed and transcoding has been enabled using the `CSI2_CTX_CTRL1_i[27:24]` TRANSCODE bit field.
- Data sent to the video port cannot be compressed: it is intended to be processed by the ISS ISP. Data sent to system memory can be optionally compressed.
- Internal data are aligned on MSB when they enter the cropping stage. For example:
 - 4 LSBs are 0s when RAW10 data are handled.
 - 2 LSBs are 0s when RAW12 data are handled.

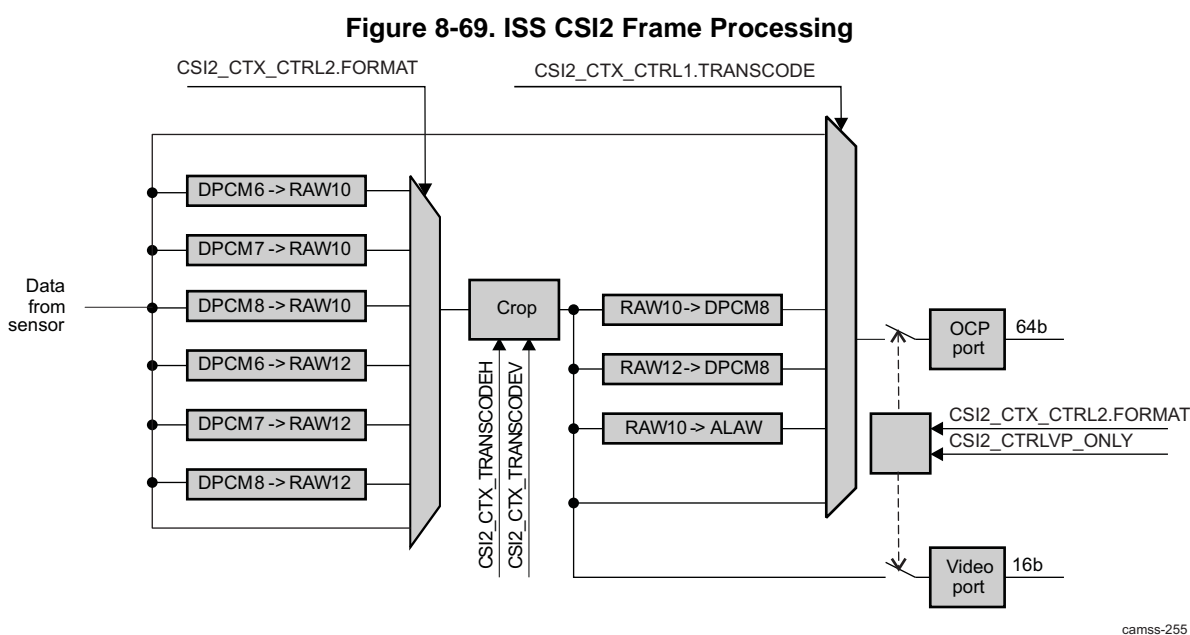

Table 8-143 shows the input format provided to the cropping engine for a given pixel format provided by the sensor. Formats not listed in the table are not supported for transcoding. The FORMAT and Corresponding Setting Value column corresponds to the value set in the `CSI2_CTX_CTRL2_i[9:0]` FORMAT register.

Table 8-143. ISS CSI2 Supported Transcoding Input Formats

| CSI2_CTX_CTRL2_i[9:0] FORMAT and Corresponding Setting Value | | Cropping Engine Input Format | DPCM Decomposition Enabled | Video Port Enabled |
|--------------------------------------------------------------|--------------------|------------------------------|----------------------------|--------------------|
| 0x028 | RAW6 | RAW6 | | |
| 0x068 | RAW6 + EXP8 | | | |
| 0x029 | RAW7 | RAW7 | | |
| 0x069 | RAW7 + EXP8 | | | |

| 0x3A8 | RAW6 + DPCM12 + EXP16 | Yes | | | |
| 0x368 | RAW6 + DPCM12 + VP | Yes | | Yes | |
| 0x369 | RAW7 + DPCM12 + EXP16 | Yes | | | |
| 0x3A9 | RAW7 + DPCM12 + VP | Yes | | Yes | |
| 0x02D | RAW14 | RAW14 | | | |
| 0x0AD | RAW14 + EXP16 | | | | |
| 0x12D | RAW14 + VP | | | | Yes |

Image cropping parameters are controlled by software. [Figure 8-70](#) shows the cropping operation.

Figure 8-70. ISS CSI2 Frame Cropping

CAUTION

Hardware does not check for validity of the settings. The following rules must be respected:

- [CSI2_CTX_TRANSCODEH_i\[12:0\]](#) HSKIP + [CSI2_CTX_TRANSCODEH_i\[28:16\]](#) HCOUNT \leq image width
- [CSI2_CTX_TRANSCODEV_i\[12:0\]](#) VSKIP + [CSI2_CTX_TRANSCODEV_i\[28:16\]](#) VCOUNT \leq image height

Furthermore, the [CSI2_CTX_TRANSCODEH_i\[28:16\]](#) HCOUNT bit field must comply with the following alignment constraints; otherwise, undefined behavior occurs. [Table 8-144](#) shows the transcode alignment constraints

Table 8-144. ISS CSI2 Transcode Alignment Constraints

| CSI2_CTX_CTRLi[27:24] TRANSCODE Value | Transcode | HCOUNT Must Be Multiple of |
|---------------------------------------|---------------|----------------------------|
| 0x0 | Disabled | 1 |
| 0x1 | DPCM10 RAW8 | 1 |
| 0x2 | DPCM12 RAW8 | 1 |
| 0x3 | ALAW10 RAW8 | 1 |
| 0x4 | RAW8 | 1 |
| 0x5 | RAW10 + EXP16 | 1 |
| 0x6 | RAW10 | 4 |
| 0x7 | RAW12 + EXP16 | 1 |
| 0x8 | RAW12 | 2 |
| 0x9 | RAW10 + EXP16 | 4 |

The [CSI2_CTX_CTRL1_i\[28\]](#) HSCALE configuration register enables horizontal downscaling of RAW data. It reduces the horizontal size and pixel clock by a factor of 2. The scaler uses a 2-tap horizontal filter operating on samples of the same color plane. The coefficients are: $[1/2 ; 0 ; 1/2]$

[Figure 8-71](#) shows the scaler operation.

Figure 8-71. ISS CSI2 Horizontal Scaler

camss-710u

The scaler can send data to the video port or the interface port. When data goes to the video port, no additional alignment constraints apply. But when data goes to the interface port, HCOUNT/2 must comply with the constraints from [Table 8-144](#) (for example, for RAW10, HCOUNT must be a multiple of 8).

[Table 8-145](#) lists possible combinations of input and output formats supported by the transcoding engine. The Transcode column corresponds to the [CSI2_CTX_CTRL1_i\[27:24\]](#) TRANSCODE bit field of a context.

Table 8-145. ISS CSI2-Supported Transcoding Output Formats

| Cropping Engine Output | Transcode | | Supported | Cropping Engine Output | Transcode | | Supported |
|------------------------|-----------|---------------|-----------|------------------------|-----------|---------------|-----------|
| | | | | | | | |
| RAW6 | 0 | Disabled | Yes | RAW10 | 0 | Disabled | Yes |
| | 1 | DPCM10 RAW8 | | | 1 | DPCM10 RAW8 | Yes |

| | 4 | RAW8 | Yes | | 4 | RAW8 | |
| | 5 | RAW10 + EXP16 | | | 5 | RAW10 + EXP16 | |
| | 6 | RAW10 | | | 6 | RAW10 | |
| | 7 | RAW12 + EXP16 | | | 7 | RAW12 + EXP16 | |
| | 8 | RAW12 | | | 8 | RAW12 | |
| | 9 | RAW14 | | 9 | RAW14 | Yes | |

RAW pixels are packed into 64-bit words sent to the OCP master port, as defined in:

- [Section 8.2.5.1.1.4.3.3, ISS CSI2 RAW8](#)
- [Section 8.2.5.1.1.4.3.4, ISS CSI2 RAW10](#)
- [Section 8.2.5.1.1.4.3.5, ISS CSI2 RAW12](#)
- [Section 8.2.5.1.1.4.3.6, ISS CSI2 RAW14](#)

For RAW10 and RAW12, software can choose among packed and nonpacked storage. A-Law and DPCM-compressed pixels are stored as RAW8 data: each RAW8 container holds a compressed data point.

Similarly, RAW data is sent over the video port, as described in:

- [Section 8.2.5.1.1.4.3.3, ISS CSI2 RAW8](#)
- [Section 8.2.5.1.1.4.3.4, ISS CSI2 RAW10](#)
- [Section 8.2.5.1.1.4.3.5, ISS CSI2 RAW12](#)
- [Section 8.2.5.1.1.4.3.6, ISS CSI2 RAW14](#)

Enabling of the OCP/video port is controlled by the [CSI2_CTX_CTRL2_i\[9:0\] FORMAT](#) bit field and the [CSI2_CTRL\[11\] VP_ONLY_EN](#) and [CSI2_CTX_CTRL1_i\[2\] VPFORCE](#) bits.

To enable transcoding, software configures the context normally and also configures the framing using the [CSI2_CTX_TRANSCODEV_i](#) and [CSI2_CTX_TRANSCODEH_i](#) registers. Software defines the after transcoding with the [CSI2_CTX_CTRL1_i\[27:24\]](#) TRANSCODE bit field.

8.2.5.3.3.8 ISS CSI2 EndOfFrame and EndOfLine (EOF and EOL) Pulses

The CSI2 receiver generates two signals to qualify the last pixel of a frame and the last pixel of a line to the TCTRL. It is active during or after the adequate interface bridge transaction and becomes inactive before the first transaction of the next line. Software can enable/disable generation of those signals for each context using the [CSI2_CTX_CTRL1_i\[7\]](#) EOF_EN and [CSI2_CTX_CTRL1_i\[6\]](#) EOL_EN bits. When data is sent to both OCP and video ports, the EOL/EOF timing defined for the OCP port is used.

8.2.5.3.3.9 ISS CSI2 Data Decompression

The data compression technique used is DPCM and PCM.

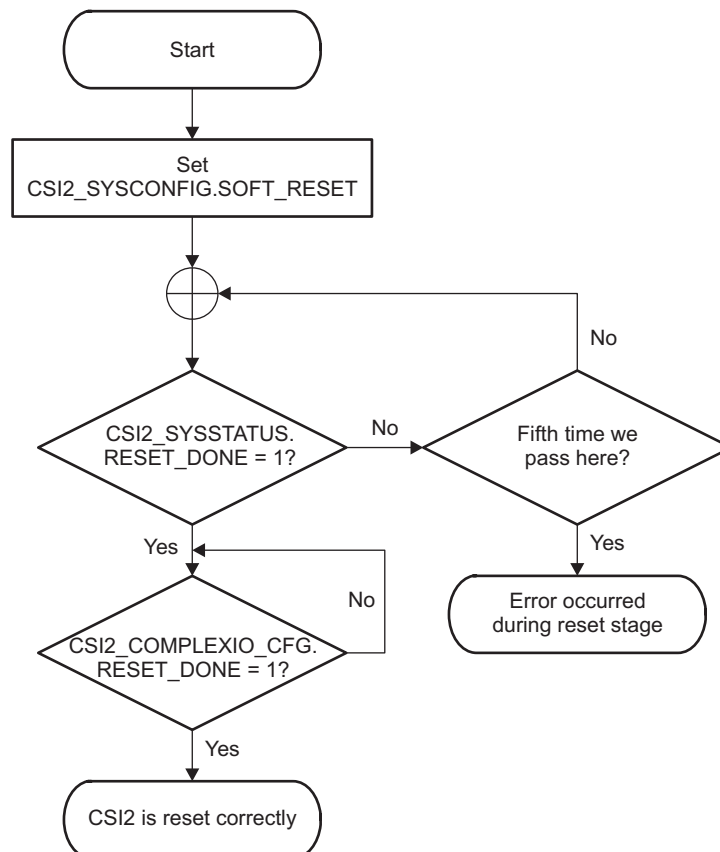

To select the DPCM decompression predictor for the CSI2 Interface, set the [CSI2_CTX_CTRL2_i\[10\]](#) DPCM_PRED bit to 1 for simple predictor or to 0 for advanced predictor.

8.2.5.4 ISS CSI2 Programming Model

8.2.5.4.1 ISS CSI2 Programming Reset Management

The CSI2 receiver accepts a general software reset, propagated throughout the hierarchy. This reset can be done to initialize the CSI2 receiver and the complex I/O (A or B) and has the same effect as a hardware reset. [Figure 8-72](#) shows how to reset CSI2 globally.

Figure 8-72. ISS CSI2 Receiver Global Reset Flow Chart

camss-252

NOTE: Before setting the software reset bit to 1 in the [CSI2_SYSCONFIG](#) register, the user must have access to a CSI2 receiver register.

NOTE: The [CSI2_COMPLEXIO_CFG](#)[29] RESET_DONE bit is set to 1 only after the initialization of the CSI2 receiver, CSI2 complex I/O, and external camera completes.

8.2.5.4.2 ISS CSI2 Programming Enable Video/Picture Acquisition

Before using the receiver, a CSIPHY initialization in CSI2 mode must be made for CSI2-A CAMERARX, which is associated with the CSI2 receiver. See [Section 8.2.3.2.2, ISS CSI2 PHY and Link Initialization Sequence](#). To start a video/picture acquisition, perform the steps listed in [Table 8-146](#).

Table 8-146. ISS CSI2 Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------|------------|
| Reset the CSI2 receiver. | See Section 8.2.5.4.1, Reset Management . | |
| Configure the module power management. The module tries to enter smart-standby mode during the vertical blanking period. The CSI2_SYSCONFIG [0] AUTO_IDLE bit keeps its reset value; by default, an automatic port clock gating strategy is applied based on port interface activity. | CSI2_SYSCONFIG [13:12] MSTANDBY_MODE | 0x2 |
| Configure the interrupt generation as required. To enable context and/or complex I/O event reporting, enable the corresponding bit field in the CSI2_IRQENABLE register. If the enable bit is at 0, logging is still effective if an event occurs, but is not reported to a higher level. | CSI2_IRQSTATUS and CSI2_IRQENABLE | |
| Configure the complex I/O interrupt generation as required. If the enable bit is at 0, logging is still effective if an event occurs, but is not reported to a higher level. | CSI2_COMPLEXIO_IRQSTATUS and CSI2_COMPLEXIO_IRQENABLE) | |
| Start complex I/O: Set the CSI2_COMPLEXIO_CFG [28:27] PWR_CMD bit field to 0x1 to pass the complex I/O to the ON state, and then check that the state status reaches the ON state (CSI2_COMPLEXIO_CFG [26:25] PWR_STATUS = 0x1) (for complex I/O A). | CSI2_COMPLEXIO_CFG [28:27] PWR_CMD | 0x1 |
| Configure the complex I/O: <ul style="list-style-type: none"> The complex I/O is fully functional with CSI2_COMPLEX_CFG set at its reset value. CSI2_COMPLEX_CFG must be changed according to the data rate being used. | CSI2_COMPLEXIO_CFG | |
| Set RXMODE and STOPSTATE FSM to RXMODE state. Users can also configure the delay for the FSM to return from RXMODE to NORXMODE when all lines reach STOPSTATE. | CSI2_TIMING [15] FORCE_RX_MODE_IO1 | 0x1 |
| Activate ECC correction and error detection on short packets and packet headers. The ECC check corrects the packet if there is one error and generates an error if there is more than one error (unrecoverable error). | CSI2_CTRL [2] ECC_EN | 0x1 |
| Start the CSI2 receiver. | CSI2_CTRL [0] IF_EN | 0x1 |
| Configure the different contexts to be used. | | |
| Link the context to a virtual channel and a data type. | See Section 8.2.5.4.6, Linking a Context to a Virtual Channel and a Data Type . | |
| Set the FEC_NUMBER bit field to 0x1 for a progressive video and to 0x2 for an interlaced video. For more information, see Section 8.2.5.3.3.5, DMA Engine . | CSI2_CTX_CTRL1_i [26:23] FEC_NUMBER | 0x1 or 0x2 |

Table 8-146. ISS CSI2 Global Initialization (continued)

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|-------|
| Capture an infinite number of frames (until the interface or the context is disabled). | CSI2_CTX_CTRL1_i[15:8] COUNT and CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK | 0x0 |
| Enable the CRC checksum on long packet payload. This allows detection of errors, but cannot correct errors like the ECC for header and short packet. On error detection, an event is triggered (the CSI2_CTX_IRQSTATUS_i[5] CS_IRQ bit). | CSI2_CTX_CTRL1_i[5] CS_EN | |
| Configure the DMA engine for the current channel: Configure the ping and pong addresses. | CSI2_CTX_DAT_PING_ADDR_i[31:5] ADDR and CSI2_CTX_DAT_PING_ADDR_i[31:5] ADDR | |
| Set the CSI2_CTX_DAT_OFST_i[15:5] OFST bit field to 0x0 so consecutive lines are stored consecutively in memory (image width and frame-buffer width are equal). | CSI2_CTX_DAT_OFST_i[15:5] OFST | |
| Keep the ALPHA setting at its reset value (0x0) for RGB padding. | CSI2_CTX_CTRL3_i[29:16] ALPHA | |
| Enable the contexts. | CSI2_CTX_CTRL1_i[0] CTX_EN | 0x1 |

8.2.5.4.3 ISS CSI2 Programming Disable Video/Picture Acquisition

There are two ways to end picture acquisition:

- Disable the corresponding context by setting the [CSI2_CTX_CTRL1_i\[0\] CTX_EN](#) bit to 0. This stops the acquisition for the current context. Other enabled contexts are still capturing frames and writing them in memory.
- Disable the CSI2 receiver interface by setting the [CSI2_CTRL\[0\] IF_EN](#) bit to 0. This can have an immediate effect if the [CSI2_CTRL\[3\] FRAME](#) bit is set to 0, or it can be effective after all the enabled contexts receive the FEC if the [CSI2_CTRL\[3\] FRAME](#) bit is set to 1.

8.2.5.4.4 ISS CSI2 Programming Capture a Finite Number of Frames

The CSI2 receiver can be configured to capture a finite number of frames. To configure the CSI2 receiver in this mode, perform the steps listed in [Table 8-147](#).

Table 8-147. ISS CSI2 Capture a Finite Number of Frames

| Step | Bit Field | Value |
|---------------------------------------------------------------------------|--------------------------------------------------|--------------------------------------------------------------------------------------------------------|
| Enable a write to the COUNT bit field. | CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK | 0x1 |
| Set the bit field to the number of frames the CSI2 receiver must capture. | CSI2_CTX_CTRL1_i[15:8] COUNT | Valid values are 0 to 255; 0 is infinite capture and 1 to 255 defines the number of frames to capture. |
| Disable a write to the COUNT bit field. | CSI2_CTX_CTRL1_i[4] COUNT_UNLOCK | 0x0 |

During frame capture, the COUNT bit field is decremented by 1 at each frame capture. Software reads the COUNT bit field to know how many frames must still be captured.

The COUNT bit can be updated during capture if the COUNT_UNLOCK bit is set to 1.

8.2.5.4.5 ISS CSI2 Programming a Periodic Event During Frame Acquisition

The CSI2 receiver can generate a periodic event. This line number is defined in the [CSI2_CTX_CTRL3_i\[15:0\] LINE_NUMBER](#) bit field. The event can be generated once or multiple times per frame, depending on the value of the [CSI2_CTX_CTRL1_i\[1\] LINE_MODULO](#) bit:

- If the LINE_MODULO bit = 0, the event is generated when the line number corresponding to the LINE_NUMBER bit field is received.
- If the LINE_MODULO bit = 1, the event is generated when the line number received corresponds to a multiple of the LINE_NUMBER value (LINE_NUMBER is used as a modulo).

8.2.5.4.6 ISS CSI2 Programming a Context to a Virtual Channel and a Data Type

The CSI2 receiver supports eight contexts and the CSI2 protocol defines four virtual channels. Therefore, a CSI2 receiver context can be associated with a virtual channel and a data type. Virtual channels are defined by a 2-bit field. Valid data types for the CSI2 receiver with their associated values are described in the [CSI2_CTX_CTRL2_i\[9:0\]](#) FORMAT bit field.

For each context, a [CSI2_CTX_CTRL2_i](#) register defines with which channel and data type the context is associated:

- The VIRTUAL_ID bit field defines the associated virtual ID transported by the CSI2 protocol from the camera sensor.
- The FORMAT bit field defines the associated data type. The data type is a combination of the data type transported by the CSI2 protocol and the type of storage in memory. A given data type (RGB888) can be stored in memory in different ways (RGB888 or RGB888 + EXP32). Therefore, the FORMAT bit field also defines how DMA stores data in memory.

For example, for the current context to capture a frame from virtual channel 2 and data type RAW12 with data expansion (RAW12 + EXP16), write the value 0x10AC (0x2 11 + 0xAC) in the 16 LSBs of the [CSI2_CTX_CTRL2_i](#) register.

8.2.5.4.7 ISS CSI2 Programming Progressive and Interleaved Frame Configuration

The CSI2 receiver can treat progressive and interlaced frames. There is no progressive or interleaved mode, but the [CSI2_CTX_CTRL1_i\[23:16\]](#) FEC_NUMBER bit field controls the number of FECs before swapping to the other (ping or pong) buffer. Therefore, two modes are possible:

- FEC_NUMBER = 1: This is equivalent to progressive mode. After a FEC on the context, the current buffer is switched (ping to pong or pong to ping). The image in the memory buffer consists of one transmitted frame.
- FEC_NUMBER 1: The current buffer is switched (ping to pong or pong to ping) after the FEC_NUMBER FEC is received for the context. The image in the memory buffer consists of the FEC_NUMBER transmitted frame.

For more information about how data is stored in memory through the DMA, see [Section 8.2.5.3.3.5, DMA Engine](#).

NOTE: If FEC_NUMBER 1, the camera sensor must send the line number information with the current line. Otherwise, the CSI2 receiver cannot calculate each line address.

8.2.5.4.8 ISS CSI2 Programming Progressive and Interleaved Frame Configuration

[Table 8-148](#) lists the procedure to enable debug mode.

Table 8-148. ISS CSI2 Enable Debug Mode

| Step | Bit | Value |
|--------------------|-------------------------------------|-------|
| Enable debug mode. | CSI2_CTRL[7] DBG_EN | 0x1 |

- During debug mode the input does not come from the CSI2 receiver interface but from the [CSI2_DBG_H](#) and [CSI2_DBG_P](#) registers. The full CSI2 receiver function can be debugged in debug mode. Full 32-bit values must always be written to the [CSI2_DBG_H](#) register. The [CSI2_CTRL\[0\]](#) IF_EN bit has no affect during debug mode. To reset the FIFO in case of overflow, the [CSI2_CTRL\[7\]](#) DBG_EN bit must be reset to 0, and the interface must be enabled by setting the [CSI2_CTRL\[0\]](#) IF_EN bit to 0x1.
- The [CSI2_DBG_H](#) register is used to provide short packet and long packet headers.
- The [CSI2_DBG_P](#) register is used to provide long packet payload.

The following examples apply to the [CSI2_DBG_H](#) register:

- The sync codes for virtual channel 0 are written as [CSI2_DBG_H](#) = 0xFF00 0000 or 0xFF00 0001, or 0xFF00 0002 or 0xFF00 0003. To send the RAW12 pixels 0x673, 0x452, 0x01d, 0xefc, 0xab0, 0x891,

0x326, 0x547, write `CSI2_DBG_H` = 0x0123 4567, followed by `CSI2_DBG_H` = 0x89abcdef, and `CSI2_DBG_H` = 0x7654 3210.

8.2.5.5 ISS CSI2 Register Manual

8.2.5.5.1 ISS CSI2 Instance Summary

Table 8-149 summarizes the CSI2 instance.

Table 8-149. ISS CSI2 Instance Summary

| Module Name | L3 Base Address | Size |

| RESERVED | | | | | | | | | | | | | | | | BURST_SIZE_EXPAND | VP_CLK_EN | RESERVED | NON_POSTED_WRITE | RESERVED | VP_ONLY_EN | STREAMING_32_BIT | VP_OUT_CTRL | DBG_EN | BURST_SIZE | ENDIANNESS | FRAME | ECC_EN | RESERVED | IF_EN | | | | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:17 | RESERVED | Reserved | R | 0x0000 |
| 16 | BURST_SIZE_EXPAND | Sets the DMA burst size on the L3 interconnect. 0x0: Use the burst size defined in the BURST_SIZE register 0x1: Allow generation of 16x64-bit bursts | RW | 0 |
| 15 | VP_CLK_EN | VP clock enable. 0x0: The VP clock is disabled. 0x1: The VP clock is enabled. | RW | 0 |
| 14 | RESERVED | Read returns reset value | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 13 | NON_POSTED_WRITE | Not posted writes 0x0: Disable 0x1: Enable | RW | 0 |
| 12 | RESERVED | | R | 0 |
| 11 | VP_ONLY_EN | VP only enable. 0x0: The VP is enabled and the OCP master port is enabled. 0x1: The VP is enabled and the OCP master port is disabled. | RW | 0 |
| 10 | STREAMING_32_BIT | Indicates if 64-bit or 32-bit streaming burst is used. Valid only if CSI2_CTRL.STREAMING=1 0x0: 64-bit streaming burst is used; byte enable pattern is 0xFF 0x1: 32-bit streaming burst is used; byte enable pattern is 0x0F | RW | 0 |
| 9:8 | VP_OUT_CTRL | VP_PCLK control. Sets the VP_PCLK as a function of the ISS interconnect interface clock (OCPCLK). 0x0: No division: VP_PCLK = OCPCLK. 0x1: Division by 2: VP_PCLK = OCPCLK / 2. 0x3: Division by 4: VP_PCLK = OCPCLK / 4. 0x2: Division by 3: VP_PCLK = OCPCLK / 3. Example scenarios: - Low VP_PCLK, Memory -> VP: Same as typical memory -> VP, but VP_PCLK = OCPCLK/2 - Typical sensor -> VP: Autoidle enabled, FCLK at optimal rate, sensor provides DPCM compressed RAW12 data at 650 Mbps. Image timings VP_PCLK = (OCPCLK/2) and CCP2_CTRL[31:15] FRACDIV = 0xD000 2600 active pixels/line, 128 blanking pixels, no vertical blanking. (This scenario corresponds to the OTF operation at maximum CCP2 speed.) | RW | 0x0 |
| 7 | DBG_EN | Enables the debug mode. 0x0: Disable 0x1: Enable | RW | 0 |
| 6:5 | BURST_SIZE | Sets the DMA burst size on the L3 interconnect. 0x0: 1x64 OCP writes 0x1: 2x64 OCP writes 0x3: 8x64 OCP writes 0x2: 4x64 OCP writes | RW | 0x0 |
| 4 | ENDIANNESS | Select endianness for YUV4:2:2 8 bit and YUV4:2:0 legacy formats. 0x0: Use native MIPI CSI2 endianness: Little endian for all formats except for YUV4:2:2 8b and YUV4:2:0 Legacy which a big endian. 0x1: Store all pixel formats little endian. | RW | 0 |
| 3 | FRAME | Set the modality in which IF_EN works. 0x0: If IF_EN = 0 the interface is disabled immediately. 0x1: If IF_EN = 1 the interface is disabled after all FEC sync code have been received for the active contexts. | RW | 0 |
| 2 | ECC_EN | Enables the Error Correction Code check for the received header (short and long packets for all virtual channel ids). 0x0: Disabled 0x1: Enabled | RW | 0 |
| 1 | RESERVED | Read returns reset value | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 0 | IF_EN | <p>Enables the physical interface to the module.</p> <p>0x0: The interface is disabled. If FRAME = 0, it is disabled immediately. If FRAME = 1, it is disabled when each context has received the FEC sync code.</p> <p>0x1: The interface is enabled immediately, the data acquisition starts on the next FSC sync code. Writing 1 to this register when the current value is 0 has the effect to clear the output FIFO. The pixel data of the following frame will be written in the PING buffer, that is, the CSI2_CTX_CTRL.PING_PONG bits are reset to 0 as well.</p> | RW | 0 |

|-------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31 | RESERVED | | R | 0 |
| 30 | RESET_CTRL | Controls the reset of the complex I/O 0x0: Complex I/O reset active. 0x1: Complex I/O reset deasserted. | RW | 0 |
| 29 | RESET_DONE | Internal reset monitoring of the power domain using the byte clock provided by the associated CSIPHY (see Section 8.1.1, ISS Clock Domains). Caution: For the CSI2_COMPLEXIO_CFG[29] RESET_DONE bit to be set to 0x1 (reset completed), the external sensor must be active and sending the MIPI HS BYTECLK. Read 0x1: Reset completed. Read 0x0: Internal module reset is on going. | R | 0 |
| 28:27 | PWR_CMD | Command for power control of the complex I/O 0x0: Command to change to OFF state 0x1: Command to change to ON state 0x2: Command to change to Ultralow-Power state | RW | 0x0 |
| 26:25 | PWR_STATUS | Status of the power control of the complex I/O Read 0x2: Complex I/O in Ultralow-Power state Read 0x1: Complex I/O in ON state Read 0x0: Complex I/O in OFF state | R | 0x0 |
| 24 | PWR_AUTO | Automatic switch between ULP and ON states based on ULPM signals from complex I/O 0x0: Disable 0x1: Enable | RW | 0 |
| 23:20 | RESERVED | | R | 0x0 |
| 19 | DATA4_POL | +/- differential pin order of data lane 4. 0x0: +/- pin order 0x1: -/+ pin order | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 18:16 | DATA4_POSITION | <p>Position and order of the data lane 4. The values 6 and 7 are reserved. This lane is not available to the CSI2-B receiver.</p> <p>0x0: This data lane is not used.</p> <p>0x1: Data lane 4 is at position 1. This position is not available to the CSI2-B receiver.</p> <p>0x2: Data lane 4 is at position 2. This position is not available to the CSI2-B receiver.</p> <p>0x3: Data lane 4 is at position 3. This position is not available to the CSI2-B receiver.</p> <p>0x4: Data lane 4 is at position 4. This position is not available to the CSI2-B receiver.</p> <p>0x5: Data lane 4 is at position 5. This position is not available to the CSI2-B receiver.</p> <p>0x6: Reserved</p> <p>0x7: Reserved</p> | RW | 0x0 |
| 15 | DATA3_POL | <p>+/- differential pin order of data lane 3.</p> <p>0x0: +/- pin order</p> <p>0x1: -/+ pin order</p> | RW | 0 |
| 14:12 | DATA3_POSITION | <p>Position and order of the data lane 3. The values 6 and 7 are reserved. This lane is not available to the CSI2-B receiver.</p> <p>0x0: This data lane is not used.</p> <p>0x1: Data lane 3 is at position 1. This position is not available to the CSI2-B receiver.</p> <p>0x2: Data lane 3 is at position 2. This position is not available to the CSI2-B receiver.</p> <p>0x3: Data lane 3 is at position 3. This position is not available to the CSI2-B receiver.</p> <p>0x4: Data lane 3 is at position 4. This position is not available to the CSI2-B receiver.</p> <p>0x5: Data lane 3 is at position 5. This position is not available to the CSI2-B receiver.</p> <p>0x6: Reserved</p> <p>0x7: Reserved</p> | RW | 0x0 |
| 11 | DATA2_POL | <p>+/- differential pin order of DATA lane 2.</p> <p>0x0: +/- pin order (csi2_dx=+ and csi2_dy=-)</p> <p>0x1: -/+ pin order (csi2_dx=- and csi2_dy=+)</p> | RW | 0 |
| 10:8 | DATA2_POSITION | <p>Position and order of the data lane 2. The values 6 and 7 are reserved. This lane is not available to the CSI2-B receiver.</p> <p>0x0: This data lane is not used.</p> <p>0x1: Data lane 2 is at position 1. This position is not available to the CSI2-B receiver.</p> <p>0x2: Data lane 2 is at position 2. This position is not available to the CSI2-B receiver.</p> <p>0x3: Data lane 2 is at position 3. | Bits | Field Name | Description | Type | Reset |
|------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31 | BYTESWAP | Allows swapping bytes two by two in the payload data. It does not affect: - short packets - long packet header or footers - CRC calculation The purpose is to by swap data send to the OCP port and/or video port 0x0: Disabled 0x1: Enabled | RW | 0 |
| 30 | GENERIC | Enables the generic mode. 0x0: Disabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is used. 0x1: Enabled. Data is received according to CSI2_CTX_CTRL1.FORMAT and the long packet code transmitted in the MIPI stream is ignored. | RW | 0 |
| 29 | RESERVED | | R | 0x0 |
| 28 | HSCALE | Enable horizontal downscaling by a factor of two. Applies to RAW data when transcoding is enabled. 0x0: Disable 0x1: Enable | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 27:24 | TRANSCODE | <p>Enables image transcoding. When this features is enabled:</p> <ul style="list-style-type: none"> - the data format from the camera is defined by the FORMAT register - the format after transcode is defined by the TRANSCODE register. The memory storage / video port formats is defined by the TRANSCODE register <p>0x6: Outputs uncompressed RAW10 data. Data in memory is organized as regular packed RAW10 data</p> <p>0x1: Outputs DPCM compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data</p> <p>0x7: Outputs uncompressed RAW12 data. Data in memory is organized as regular RAW12+EXP16 data</p> <p>0x0: Feature disabled.</p> <p>0x2: Outputs DPCM compressed RAW12 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data</p> <p>0x8: Outputs uncompressed RAW12 data. Data in memory is organized as regular packed RAW12 data</p> <p>0x9: Outputs uncompressed RAW14 data.</p> <p>0x4: Outputs uncompressed RAW8 data. Data in memory is organized as regular RAW8 data</p> <p>0x5: Outputs uncompressed RAW10 data. Data in memory is organized as regular RAW10+EXP16 data</p> <p>0x3: Outputs A-Law compressed RAW10 data. After compression, pixels are coded on 8 bits. Data in memory is organized as regular RAW8 data.</p> | RW | 0x0 |
| 23:16 | FEC_NUMBER | <p>Number of FEC to receive between using swap of CSI2_CTX_DAT_PING_ADDR and CSI2_CTX_DAT_PONG_ADDR for the calculation of the address in memory (must be used only in interlace mode, otherwise set to 1).</p> | RW | 0x01 |
| 15:8 | COUNT | <p>Sets the number of frame to acquire. Once the frame acquisition starts, the COUNT value is decremented after every frame. When COUNT reaches 0, the FRAME_NUMBER_IRQ interrupt is triggered and CTX_EN is set to 0.</p> <p>Writes to this bit field are controlled by the COUNT_UNLOCK bit. During the same OCP write access, the bit field COUNT_UNLOCK shall be written in addition to COUNT bit field in order to change the COUNT value. COUNT can be overwritten dynamically with a new count value.</p> <p>0: Infinite number of frames (no count). 1: 1 frame to acquire ... 255: 255 frames to acquire</p> | RW | 0x00 |
| 7 | EOF_EN | <p>Indicates if the end of frame signal shall be asserted at the end of the line.</p> <p>Read 0x1: The end of frame signal is asserted at the end of each frame.</p> <p>Read 0x0: The end of frame signal is not asserted at the end of each frame.</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|--------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 6 | EOL_EN | Indicates if the end of line signal shall be asserted at the end of the line. Read 0x1: The end of line signal is asserted at the end of each frame. Read 0x0: The end of line signal is not asserted at the end of each frame. | RW | 0 |
| 5 | CS_EN | Enables the checksum check for the received payload (long packet only). 0x0: Disabled 0x1: Enabled | RW | 0 |
| 4 | COUNT_UNLOCK | Unlock writes to the COUNT bit field. Write 0x0: COUNT bit field is locked. Writes have no effect Write 0x1: COUNT bit field is unlocked. Writes are possible. | W | 0 |
| 3 | PING_PONG | Indicates whether the PING or PONG destination address (CSI2_CTX_DAT_PING_ADDR or CSI2_CTX_DAT_PONG_ADDR) was used to write the last frame. This bit field toggles after every FEC_NUMBER FEC sync code received for the current context. Read 0x1: PONG buffer Read 0x0: PING buffer | R | 1 |
| 2 | VP_FORCE | Forces sending of the data to both VPORT and OCP. Only applies to formats that existing in two versions: - One sending data to OCP port only - One sending data to VPORT only (tagged with the +VP extension) The format version sending data only to OCP should be chosen. 0x0: Disabled 0x1: Enabled | RW | 0 |
| 1 | LINE_MODULO | Line modulo configuration 0x0: CSI2_CTX_CTRL3.LINE_NUMBER is used once per frame for the generation of the LINE_NUMBER_IRQ. 0x1: CSI2_CTX_CTRL3.LINE_NUMBER is used as a modulo number for the generation of the LINE_NUMBER_IRQ (multiple times the interrupt can be generated for each frame) | RW | 0 |
| 0 | CTX_EN | Enables the context 0x0: Disabled 0x1: Enabled | RW | 0 |

8.2.6 ISS TCTRL

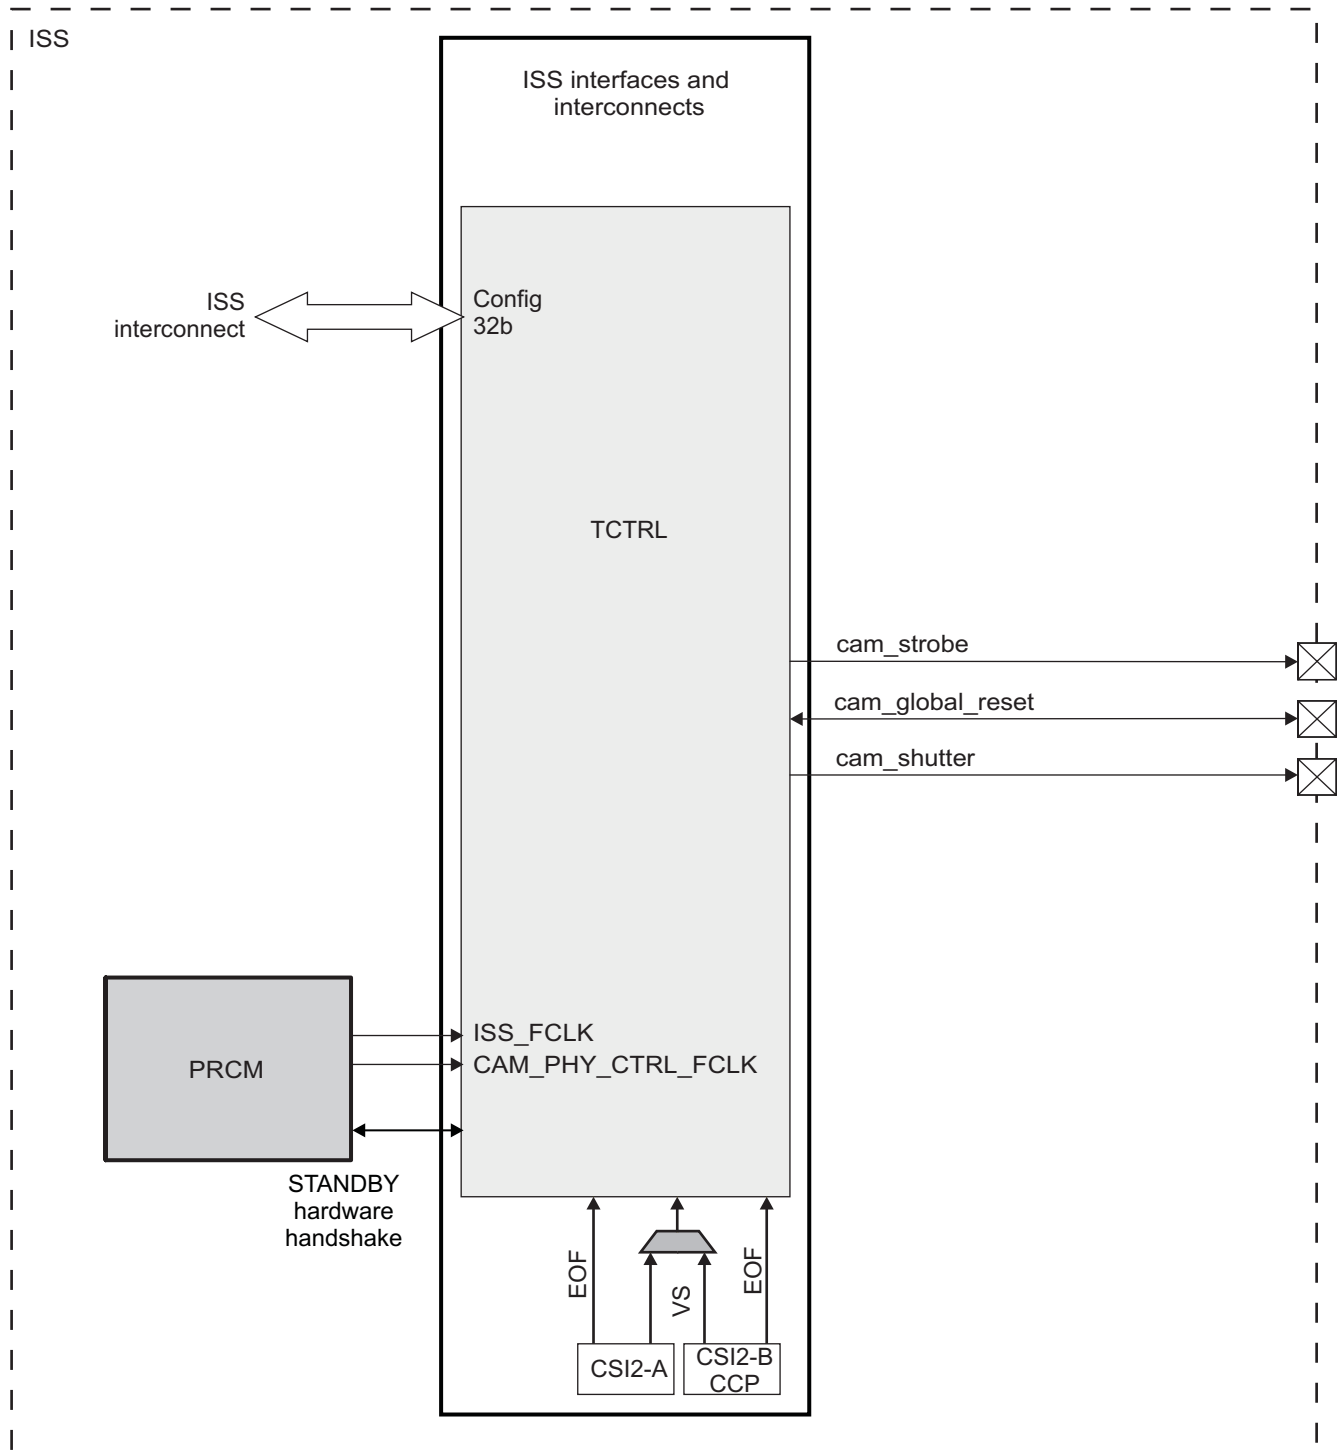

8.2.6.1 ISS TCTRL Environment

There are no particular environment attributes. See [Section 8.2.2](#), *ISS Interfaces Environment*.

8.2.6.2 ISS TCTRL Integration

[Figure 8-73](#) shows the integration of the TCTRL.

Figure 8-73. ISS TCTRL Integration

camss-355

For information about the power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

8.2.6.3 ISS TCTRL Functional Description

8.2.6.3.1 ISS TCTRL Features

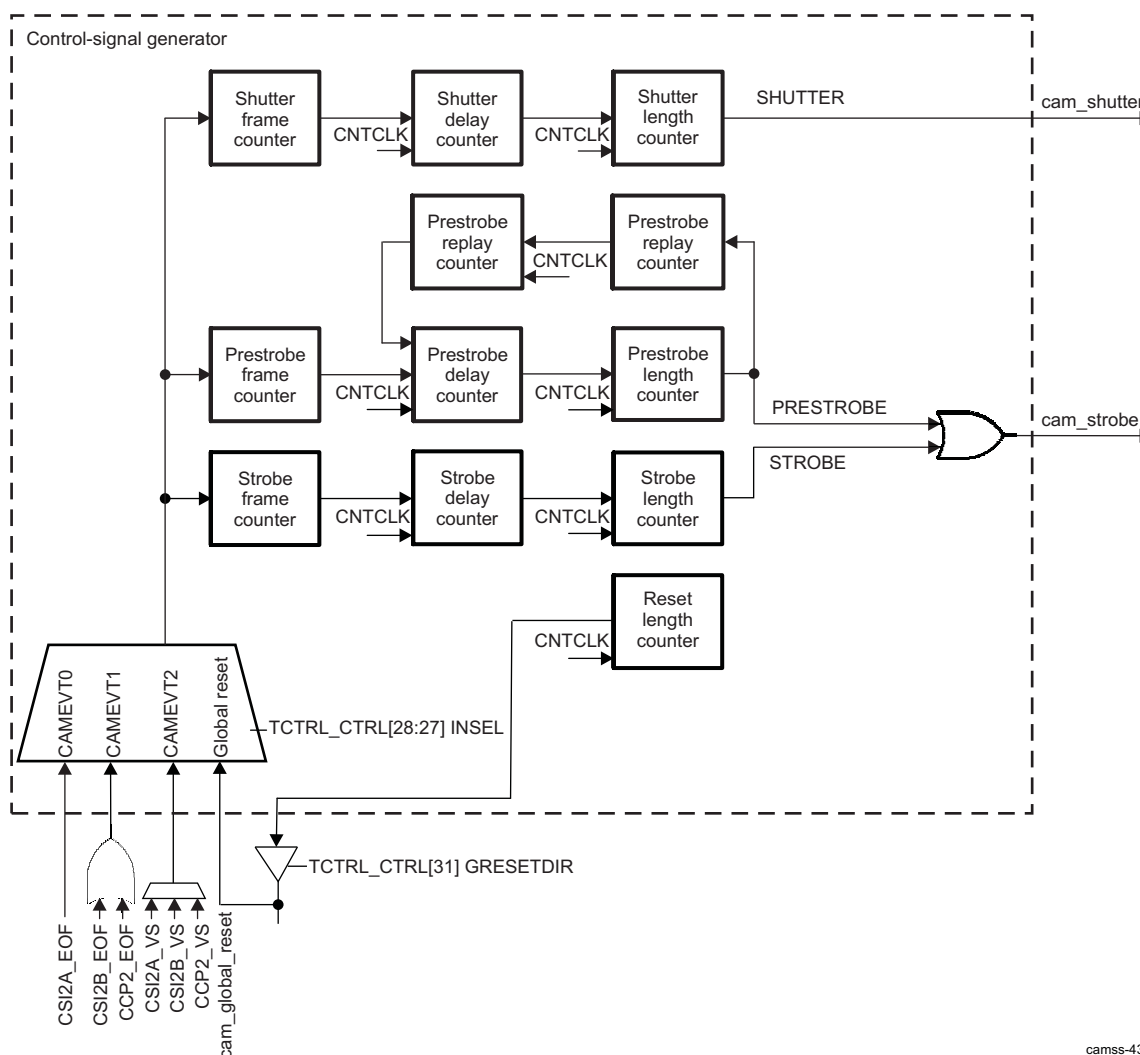

The TCTRL generates the control signals (cam_strobe and cam_shutter) for the flash prestrobe, flash strobe, and mechanical shutters.

The TCTRL includes a timing generator and a control-signal generator.

8.2.6.3.2 ISS TCTRL Control-Signal Generator

The control-signal generator generates the prestrobe, strobe, and shutter signals: cam_strobe and cam_shutter. Figure 8-74 shows the principle of control-signal generation.

Figure 8-74. TCTRL Control-Signal Generation

camss-433

The control-signal generator gathers precise timings for the cam_strobe and cam_shutter signals, to assert and deassert the signals at known times. The timing control-signal generator can be synchronized on the vertical synchronization signal coming from the CSI2-A, CSI2-B, CCP2 or on an externally generated cam_global_reset signal.

A multiplexer controls which of the CSI2-A, CSI2-B, or CCP2 interfaces drives control-signal generation. This multiplexer can also select the externally generated cam_global_reset signal as the trigger event. The TCTRL_CTRL[31] GRESETDIR bit defines the direction of cam_global_reset.

- The externally generated cam_global_reset is used as a trigger when TCTRL_CTRL[31] GRESETDIR

= 0 and **TCTRL_CTRL[28:27]** INSEL = 3.

- The internally generated `cam_global_reset` is used as a trigger when **TCTRL_CTRL[31]** GRESETDIR = 1 and **TCTRL_CTRL[28:27]** INSEL = 3.

The `cam_global_reset` signal can also be generated internally by the control-signal generator under software control. In this case, the prestrobe and shutter signals are synchronized on internally generated `cam_global_reset`. The multiplexer controls whether control-signal generation must be triggered by the internal or external `cam_global_reset`.

The prestrobe-, strobe-, and shutter-control signals can be individually enabled at any time. These signals must not be disabled by software.

The clock divider generates the CNTCLK clock based on the functional clock. The clock divider is programmable. [Table 8-198](#) lists the possible frequencies as a function of the divisor values.

Table 8-198. ISS TCTRL Control-Signal Generator: CNTCLK Frequencies

| Divisor Value TCTRL_CTRL[18:10] DIVC | CNTCLK Clock | CNTCLK Precision (ns) |
|------------------------------------------------|------------------------|-----------------------|
| 0 (default) | Clock gated. No clock. | N/A |
| 1 | 200 MHz | 5 |
| 2 | 100 MHz | 10 |
| 3 | 66,667 MHz | 15 |
| 4 | 50 MHz | 20 |
| ... | ... | ... |
| 510 | 0.392 MHz | 2550 |
| 511 | 0.391 MHz | 2555 |

There are three counters per control signal, for a total of nine counters. Each counter is programmable.

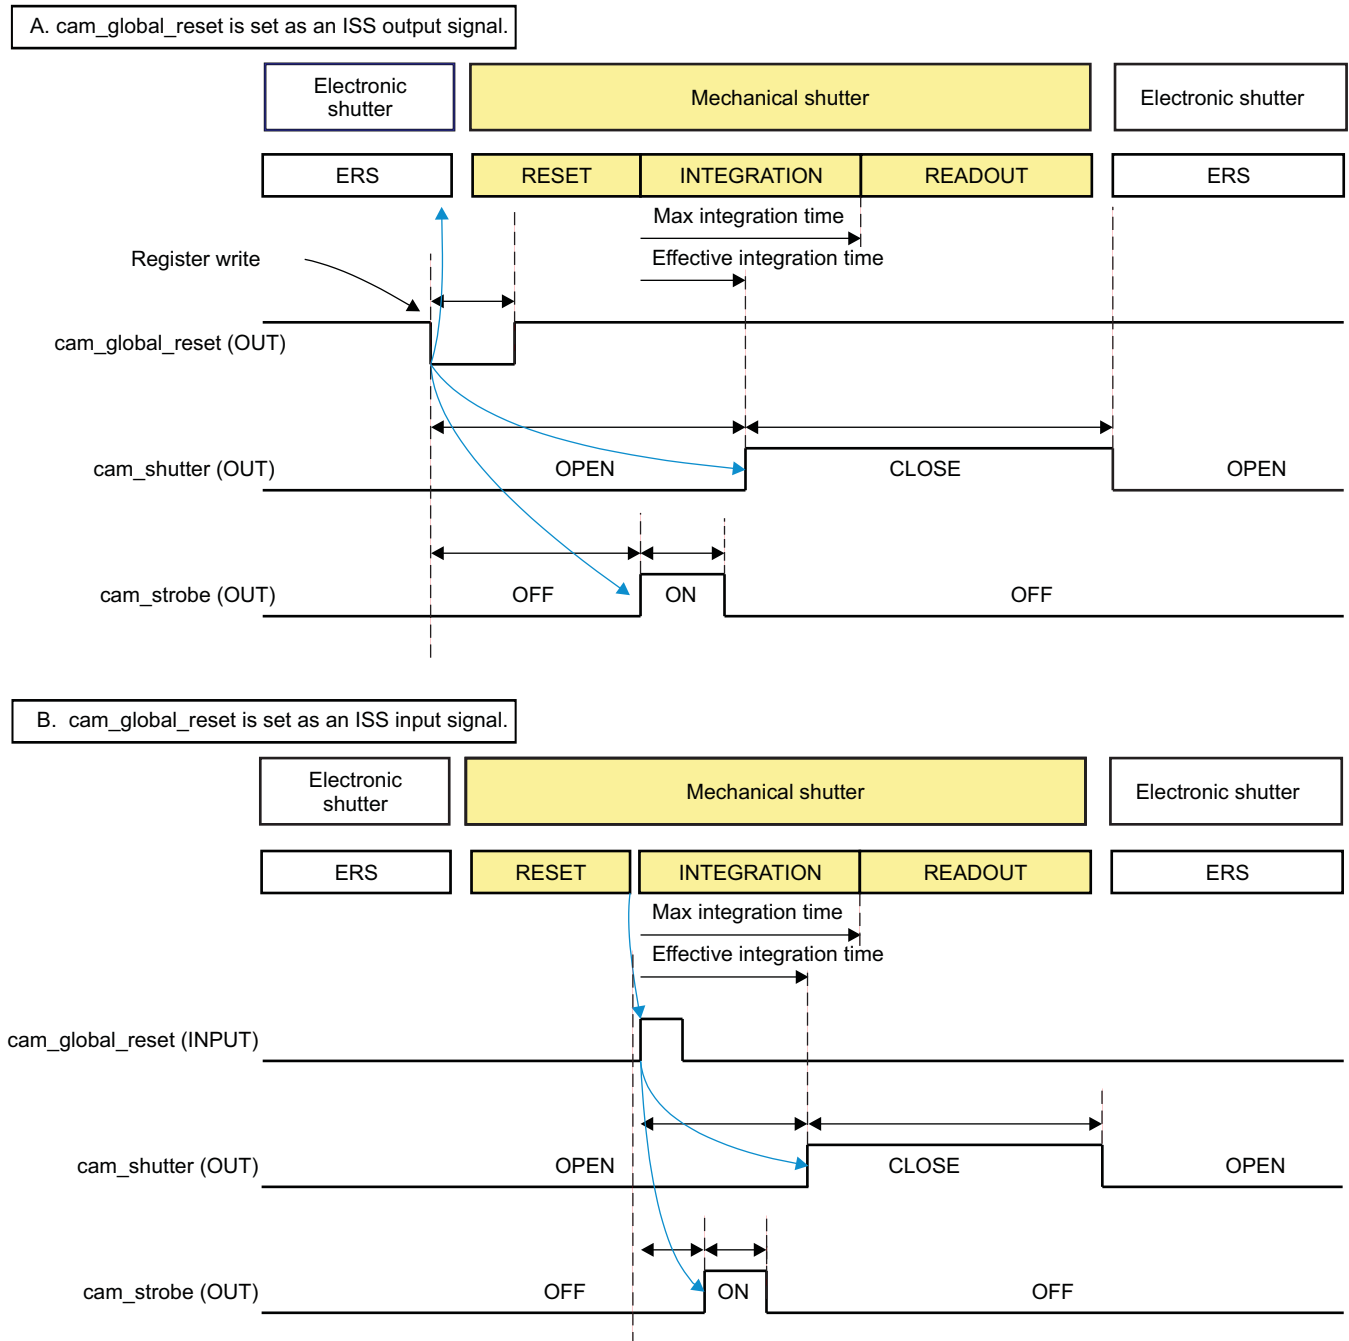

- The frame counter is decreased each time a full new frame is received.
 - A new frame is detected by the TCTRL module when CAMEVTx is received.
 - The frame counter determines how many whole frames must be ignored before the delay counter is triggered. The frame counters can be set to 0 to bypass the frame counters.
- The delay counter determines the control-signal activation delay. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the control signal is asserted. If the delay counter is set to 0, the control signal is asserted immediately.
- The activation-length counter determines the length of control-signal assertion. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the control-signal enable bit is disabled. If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled.

The polarity of the following signals can be individually selected:

- **TCTRL_CTRL[26]** STRBPSTRBPOL for the prestrobe and strobe signals
- **TCTRL_CTRL[24]** SHUTPOL for the shutter signal
- **TCTRL_CTRL[30]** GRESETPOL for `cam_global_reset`

Software can trigger the generation of `cam_global_reset` to the camera module. The length of signal-activation is programmable. The counter is decreased at every CNTCLK clock cycle. When the counter reaches 0, the signal is deasserted and the global reset enable bit is disabled (the **TCTRL_CTRL[29]** GRESETEN bit). If the activation length is set to 0, the control signal is not asserted and the control-signal enable bit is disabled. The polarity of `cam_global_reset` can be selected (the **TCTRL_CTRL[30]** GRESETPOL bit).

[Figure 8-75](#) shows the use of `cam_global_reset` set as an input or output signal. `cam_global_reset` is asynchronous, edge-sensitive, and asserted for at least one interconnect clock cycle.

Figure 8-75. ISS TCTRL Use of cam_global_reset With Global Reset Release Camera Modules

camss-434

There are two types of shutter mechanisms: mechanical and electronic. A mechanical shutter is used only for high-resolution sensors. The three control signals (cam_global_reset, cam_shutter, and cam_strobe) are useful with a mechanical shutter. High frame rates can be achieved only with an electronic shutter. When an electronic shutter is used, none of the three control signals is used.

- Mechanical shutter mechanism:
 - Reset: All pixels of the sensor are reset to their black value. When the sensor has a global reset feature, the mechanical shutter can be open during reset.
 - Integration: The light received by the sensor is transformed into electrical charges that are stored inside pixels. At the end of the integration time, the shutter must be closed. Exposure time is

defined by the time between reset release and shutter close.

- Readout: The charges accumulated in pixels are converted to digital values that are sent to the camera receiver.
- Electronic rolling shutter (ERS) mechanism:
 - Each line of the sensor is reset separately and read after a fixed amount of time. Exposure time is defined by the time between reset and read.

8.2.6.4 ISS TCTRL Programming Model

The following settings must be done before enabling the TCTRL.

8.2.6.4.1 ISS TCTRL Camera-Control Signal Generator

Two configurations apply:

- First configuration: The control signals are based on the vertical synchronization information coming from the camera module or from externally generated `cam_global_reset`.
- Second configuration: The control signals are based on internally generated `cam_global_reset`.

8.2.6.4.1.1 ISS TCTRL Vertical Sync-Based Control-Signal Generation or Externally Generated `cam_global_reset`

To enable control-signal generation in the first configuration, follow the procedure listed in [Table 8-199](#).

Table 8-199. ISS TCTRL Enabling the Control-Signal Generation in First Configuration

| Step | Bit Field | Value |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Select the input that triggers the control signals. The trigger signal can come from the CSI2-A, or CSI2-B/CCP2 interface, or the externally generated <code>cam_global_reset</code> signal. | TCTRL_CTRL[28:27] INSEL | 0x0: CSI2A 0x1: CSI2B or CCP2 0x2: VS signal 0x3: Global reset |
| Set the global reset as input signal. Writes to the TCTRL_CTRL[29] GRESETEN bit do not trigger the CAM_STROBE and CAM_SHUTTER signals and do not generate the CAM_GLOBAL_RESET signal. | TCTRL_CTRL[31] GRESETDIR | 0x0 |
| The following bits are cleared automatically to 0 after the signal assertion: | <ul style="list-style-type: none"> • TCTRL_CTRL[21] SHUTEN • TCTRL_CTRL[22] PSTRBEN • TCTRL_CTRL[23] STRBEN | |
| Set the polarity of the SHUTTER, STROBE/PRESTROBE, and <code>cam_global_reset</code> signals. | <ul style="list-style-type: none"> • TCTRL_CTRL[24] SHUTPOL • TCTRL_CTRL[26] STRBPSTRBPOL • TCTRL_CTRL[30] GRESETPOL | |
| Set the clock divisor value, which generates the CNTCLK clock. The clock is set by <code>CNTCLK = ISS_FCLK/TCTRL_CTRL[18:10] DIVC</code> . | TCTRL_CTRL[18:10] DIVC | 0x0: Disable CNTCLK 0 to 511: Divider |
| Set the frame counters. | <ul style="list-style-type: none"> • TCTRL_FRAME[5:0] SHUT • TCTRL_FRAME[11:6] PSTRB • TCTRL_FRAME[17:12] STRB | 0: TCTRL does not delay any frame in input. 1 to 63 |
| Set the delay counters. | <ul style="list-style-type: none"> • TCTRL_SHUT_DELAY • TCTRL_PSTRB_DELAY • TCTRL_STRB_DELAY | The possible values are 0 to $2^{25} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 511/200$ MHz = 85.73157376 s (TCTRL_CTRL[18:10] DIVC = 511). |

Table 8-199. ISS TCTRL Enabling the Control-Signal Generation in First Configuration (continued)

| Step | Bit Field | Value |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Set the signal durations. | <ul style="list-style-type: none"> TCTRL_SHUT_LENGTH TCTRL_PSTRB_LENGTH TCTRL_STRB_LENGTH | The possible values are 0 to $2^{24} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 200 MHz input clock is $(2^{24} - 1) \times 511/200 \text{ MHz} = 42.865784325 \text{ s}$ (TCTRL_CTRL.DIVC = 511). |
| Enable the SHUTTER signal. | TCTRL_CTRL[21] SHUTEN | 0x1 |
| Enable the PRESTROBE signal. | TCTRL_CTRL[22] PSTRBEN | 0x1 |
| Enable the STROBE signal. | TCTRL_CTRL[23] STRBEN | 0x1 |

8.2.6.4.1.2 ISS TCTRL Internally Generated cam_global_reset-Based Control-Signal Generation

To enable control-signal generation in the second configuration, follow the procedure listed in [Table 8-200](#).

Table 8-200. ISS TCTRL Enabling the Control-Signal Generation in Second Configuration

| Step | Bit Field | Value |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Select the input to global reset, to loop back the internally generated GLOBAL_RESET. Vertical synchronization events do not trigger the CAM_STROBE and CAM_SHUTTER signals. | TCTRL_CTRL[28:27] INSEL | 0x3: Global reset |
| Set the global reset as output signal. | TCTRL_CTRL[31] GRESETDIR | 0x1 |
| The following bits are cleared automatically to 0 after the signal assertion: | <ul style="list-style-type: none"> TCTRL_CTRL[21] SHUTEN TCTRL_CTRL[22] PSTRBEN TCTRL_CTRL[23] STRBEN TCTRL_CTRL[29] GRESETEN | 0x0 |
| Set the polarity of the SHUTTER, STROBE/PRESTROBE, and cam_global_reset signals. | <ul style="list-style-type: none"> TCTRL_CTRL[24] SHUTPOL TCTRL_CTRL[26] STRBPSTRBPOL TCTRL_CTRL[30] GRESETPOL | |
| Set the clock divisor value, which generates the CNTCLK clock. The clock is set by CNTCLK = ISS_FCLK/TCTRL_CTRL[18:10] DIVC. | TCTRL_CTRL[18:10] DIVC | 0x0: Disable CNTCLK 0 to 511: Divider |
| Set the frame counters. | <ul style="list-style-type: none"> TCTRL_FRAME[5:0] SHUT TCTRL_FRAME[11:6] PSTRB TCTRL_FRAME[17:12] STRB | 0: TCTRL does not delay any frame in input. 1 to 63 |
| Set the delay counters. | <ul style="list-style-type: none"> TCTRL_SHUT_DELAY TCTRL_PSTRB_DELAY TCTRL_STRB_DELAY | The possible values are 0 to $2^{25} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 511/200 \text{ MHz} = 85.73157376 \text{ s}$ (TCTRL_CTRL[18:10] DIVC = 511). |

Table 8-200. ISS TCTRL Enabling the Control-Signal Generation in Second Configuration (continued)

| Step | Bit Field | Value |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Set the signal durations. | <ul style="list-style-type: none"> TCTRL_SHUT_LENGTH TCTRL_PSTRB_LENGTH TCTRL_STRB_LENGTH | The possible values are 0 to $2^{24} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 200 MHz input clock is $(2^{24} - 1) \times 511 / 200 \text{ MHz} = 42.865784325 \text{ s}$ (TCTRL_CTRL.DIVC = 511). |
| Set the cam_global_reset assertion time. | TCTRL_GRESET_LENGTH | The possible values are 0 to $2^{24} - 1$ cycles. The cycles are at the CNTCLK clock frequency. The maximum signal duration for a 200 MHz input clock is $(2^{24} - 1) \times 511 / 200 \text{ MHz} = 42.865784325 \text{ s}$ (TCTRL_CTRL.DIVC = 511). |
| Enable the SHUTTER signal. | TCTRL_CTRL[21] SHUTEN | 0x1 |
| Enable the PRESTROBE signal. | TCTRL_CTRL[22] PSTRBEN | 0x1 |
| Enable the STROBE signal. | TCTRL_CTRL[23] STRBEN | 0x1 |
| Enable the cam_global_reset control-signal generation. | TCTRL_CTRL[29] GRESETEN | 0x1 |

NOTE: Setting the following bits to 1 simultaneously leads to unpredictable behavior:

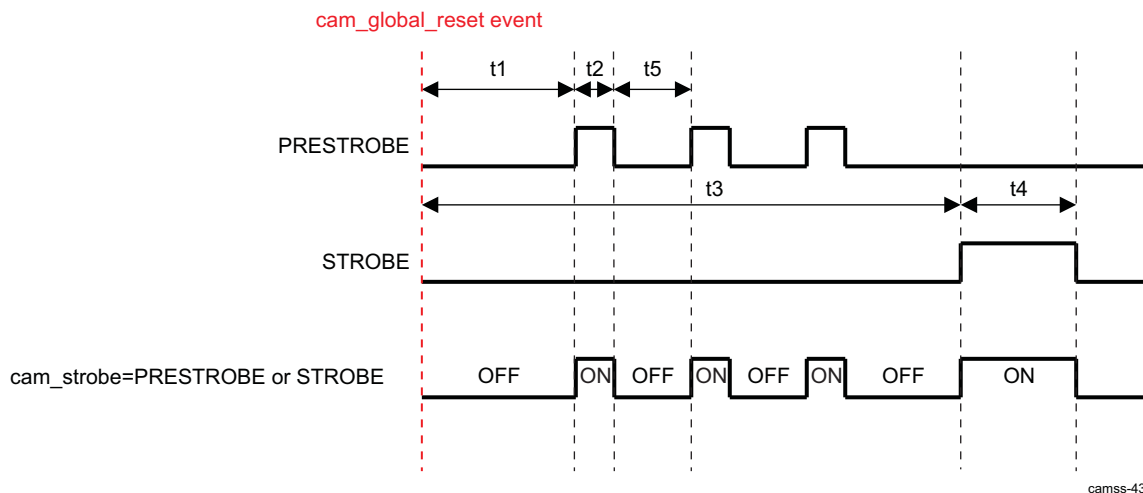

- TCTRL_CTRL[21] SHUTEN
- TCTRL_CTRL[22] PSTRBEN
- TCTRL_CTRL[23] STRBEN
- TCTRL_CTRL [29] GRESETEN

The following bits must be set before TCTRL_CTRL[29] GRESETEN is enabled:

- TCTRL_CTRL[21] SHUTEN
- TCTRL_CTRL[22] PSTRBEN
- TCTRL_CTRL[23] STRBEN

8.2.6.4.1.3 ISS TCTRL STROBE and PRESTROBE Signal Generation for Red-Eye Removal

The STROBE and PRESTROBE signal generation enables a strobe flash for red-eye removal. The process is shown in [Figure 8-76](#). The dotted line corresponds to known timings from which the delay counters start decreasing: cam_global_reset event.

Figure 8-76. cam_strobe Signal-Generation for Red-Eye Removal

- t1: Set by the [TCTRL_PSTRB_DELAY](#) register
- t2: Set by the [TCTRL_PSTRB_LENGTH](#) register
- t5: Set by the [TCTRL_PSTRB_REPLAY\[24:0\]](#) DELAY bit field. The number of times the pulse is repeated is controlled by the [TCTRL_PSTRB_REPLAY\[31:25\]](#) COUNTER bit field.
In the previous example, [TCTRL_PSTRB_REPLAY\[31:25\]](#) COUNTER = 2.
 - The possible delay values are 0 to $2^{25} - 1$ cycle. The cycles are at the CNTCLK clock frequency. The maximum signal duration is $(2^{25} - 1) \times 511/200$ MHz = 85.73157376 s ([TCTRL_CTRL\[18:11\]](#) DIVC = 511).
 - The possible count values are 0 to 127 additional pulses.
- t3: Set by the [TCTRL_STRB_DELAY](#) register
- t4: Set by the [TCTRL_STRB_LENGTH](#) register

| 31:24 | RESERVED | | R | 0x00 |
| 23:0 | LENGTH | Sets the length of the CAM_GLOBAL_RESET signal assertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. After signal assertion, the TCTRL_CTRL.GRESETEN bit is automatically cleared. The possible values are 0 to $2^{24}-1$ cycles. The polarity of the CAM_GLOBAL_RESET signal is set by the TCTRL_CTRL.GRESETPOL bit. | RW | 0x000000 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-----------|
| 31:25 | COUNTER | Sets the number of PRESTROBE pulses after the original pulse. If this bit is set to 0, the PRESTROBE signal behavior is only controlled by TCTRL_FRAME.STRB, TCTRL_PSTRB_DELAY, and TCTRL_PSTRB_LENGTH. If TCTRL_PSTRB_LENGTH=0, there is no replay. This bit is useful when one wants to enable red-eye removal. | RW | 0x00 |
| 24:0 | DELAY | Sets the delay for the PRESTROBE signal reassertion in cycles of the CNTCLK clock. The CNTCLK frequency is generated with the TCTRL_CTRL.DIVC bit field. The possible values are 0 to $2^{25}-1$ cycles. If TCTRL_PSTRB_LENGTH=0, there is no replay. This bit field shall not be set to 0 if the COUNTER is set to a value different of 0. This bit is useful when one wants to enable red-eye removal. | RW | 0x0000000 |

8.2.7 ISS BTE

8.2.7.1 ISS BTE Environment

There are no particular environment attributes (see [Section 8.2.2, ISS Interfaces Environment](#)).

8.2.7.2 ISS BTE Integration

Figure 8-77. ISS BTE Integration

camss-318

For power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

8.2.7.2.1 ISS BTE PRCM Interface

8.2.7.2.1.1 ISS BTE Power Management

8.2.7.2.1.1.1 ISS BTE PRCM Handshake

The BTE supports the IDLE protocol to flush outstanding transactions. When an IDLE request is received, the BTE:

- Completes ongoing requests on OCPI (request, data and response phases) and stalls the port (SCmdAccept = 0)
- Flushes all contexts (same behavior than when the [BTE_CONTEXT_CTRL_i\[2\]](#) FLUSH bit is set by software) when the [BTE_CONTEXT_CTRL_i\[11\]](#) AUTOFLUSH bit is set. Otherwise, no context flushing is triggered by an IDLE request.
- Completes ongoing requests on OCPO (request, data and response phases)
- Acknowledges the IDLE request.

8.2.7.3 ISS BTE Functional Description

8.2.7.3.1 ISS BTE Features

The BTE increases access efficiency of raster initiators to tiled SDRAM. In fact, the TILER expects 2D-bursts corresponding to a row or column of subtiles for maximal efficiency. For more information about SDRAM and TILER, see [Section 15.2, Dynamic Memory Manager](#).

The BTE is connected between one or multiple raster initiators. It can translate reads and writes. For reads, BTE prefetches sufficient data from tiled memory to translate raster requests. For writes, BTE buffers raster requests until it has sufficient data to generate requests to tiled memory. The features of the BTE are:

- Interfaces:
 - 32-bit-wide configuration interface (OCPC)
 - 128-bit-wide slave data port (OCPI)
 - 128-bit-wide master data port (OCPO)
- Incrementing to 2D burst translation for read and writes:
 - Four contexts. A context is a virtual frame buffer attached to a data flow requiring translation.
 - One-shot and continuous mode
- Local memories for temporal storage:
 - Cannot use external memories for temporal data storage
- Transparent for accesses that do not require translation. Requests are forwarded from OCPI to OCPO without modification.
- Local buffer

8.2.7.3.2 ISS BTE Functional Description Details

The main tasks and capabilities of the BTE are:

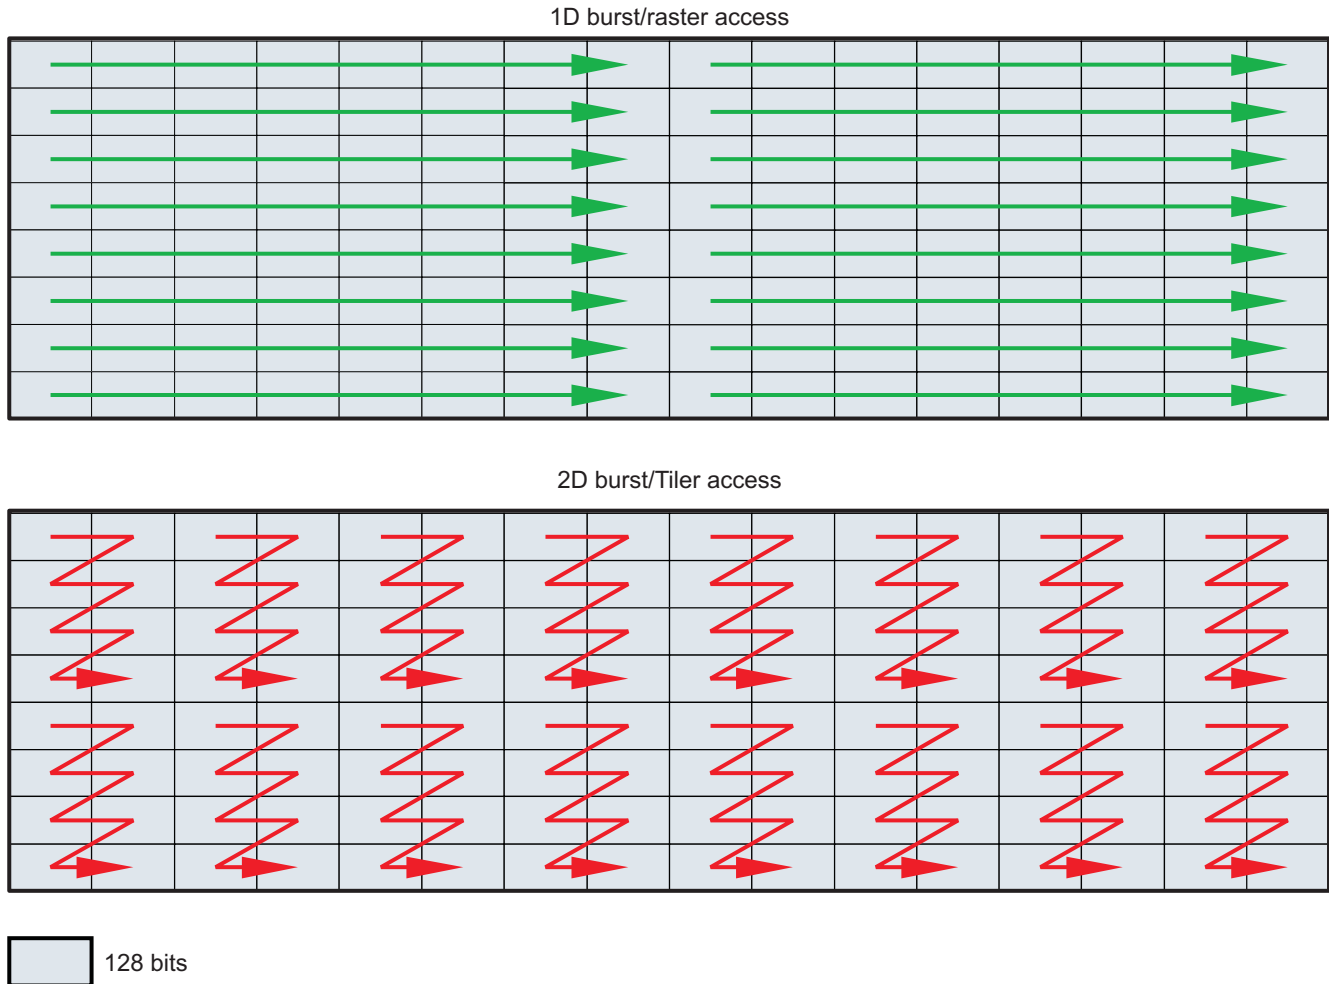

- Forward OCP transactions that do not need translation.
- For OCP writes requiring translation:
 - Store data received from OCPI to local buffers.
 - Read data from local buffers and send it to OCPO.
- For OCP read requiring translation:
 - Store data received from OCPO to local buffers.
 - Read data from local buffers and send it to OCPI.
- BTE DMA capability

8.2.7.3.2.1 ISS BTE Burst Translation Principle

The BTE receives raster accesses from the OCPI port and generates TILER accesses on OCPO.

The BTE keeps track of the amount of data written into the local memories. For translated writes, 2D bursts are sent to OCPO when there is sufficient data in the local memory to generate TILER accesses. For translated reads, 2D burst are generated to fill the local memory with data that is returned when raster accesses are received on OCPI. [Figure 8-78](#) shows the BTE burst translation principle.

Figure 8-78. ISS BTE Burst Translation Principle

camss-320

In the following sections, three address spaces are described:

- Virtual: Corresponds to the translated address region on OCPI. Accesses performed to this address space are translated by the BTE. It can be seen as a 64KB x 8 k lines frame buffer. Locations in this space are expressed as byte addresses for OCP compliance. However, the access granularity is 128-bit (4 LSBs expected to be zeros). For more information about this space, see [Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping](#).
- Physical: Corresponds to the addresses used to access the physical buffer of the BTE. The physical space is addressed in 128-bit-wide words. However, this document refers to byte addresses to preserve homogeneity.
- Tiler: Corresponds to addresses used by translated accesses. Locations in this space are expressed as byte addresses for OCP compliance. However, the access granularity is 128-bit (4 LSBs expected to be zeros). For more information about this space, see [Section 8.2.7.3.2.5, ISS BTE TILER Space Accesses: 2D Burst Generation](#).

8.2.7.3.2.2 ISS BTE Virtual Address Space and Context Mapping

The location of the virtual space in the address map of OCPI is set by the `BTE_CTRL[11:8]` BASE bit field. It always occupies 64KB × 8k lines = 512MB. Software must map a virtual space into an unused region (a region, for example, that the ISS top level cannot access).

The virtual space is decomposed into contexts. A context corresponds to a 2D region in the virtual space that requires burst translation. It can also be seen as a virtual frame buffer.

Accesses to different contexts can be interleaved at OCP transaction level. OCP transactions spanning multiple contexts are not allowed.

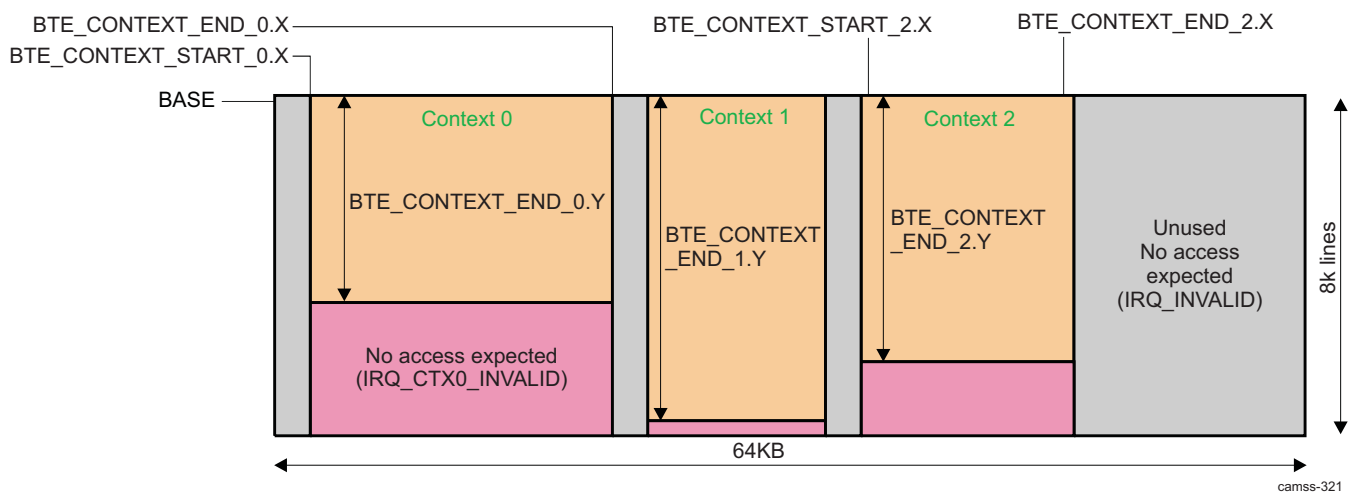

When the BTE receives an access from the OCPI port, it performs the following checks:

- If the access address is not between BASE 512MB and (BASE + 1) 512MB 1, it is handled as a transparent: request and data phases are simply forwarded to the OCPO without modification.
- If the access falls into the translated region:
 - If the access is a 2D burst, an `IRQ_INVALID` event is generated.
 - If the access does not map to an active context, an `IRQ_INVALID` event is generated. The BTE ignores bits [28:16] for this test.
 - Otherwise, context mapping is performed (see [Figure 8-79](#)).

Invalid requests are not forwarded to the OCPO.

Software must ensure that contexts do not overlap. The BTE hardware does not check for this condition. Wrong setup is likely to lead to corrupted data.

Figure 8-79. ISS BTE Context Mapping

The BTE internally keeps track of every context where the next access is expected. It internally maintains a 2D pointer, referred to as (SX_i, SY_i) in the remainder of this document. The expected byte address for an access into context x is:

$$\text{ADDR} = \text{BTE_CTRL}[11:8] \text{ BASE } 512\text{MB} + \text{SX}_i \text{ 16 bytes} + \text{SY}_i \text{ 64KB}$$

If an access to an unexpected location in a given context is received from OCPI, the BTE generates an `IRQ_CTXx_INVALID` event. The BTE provides a valid response on OCPI but does not store any data into the internal buffer. Subsequent accesses are handled normally: in other words, the BTE does not enter any specific error mode. When this happens, typically an initiator configuration is not aligned with the BTE context configuration.

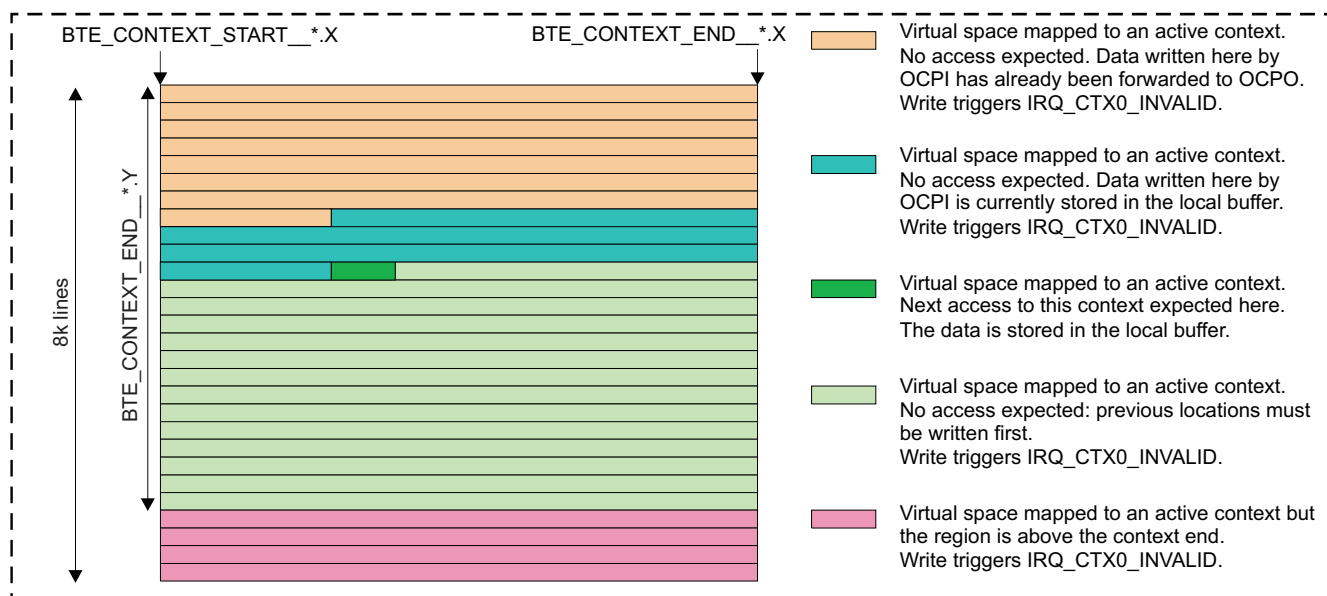

The (SX_i, SY_i) pointer of a context is updated on every access to this context. It is reset to SX_i = BTE_CONTEXT_START_i[15:7] X and SY_x = 0 when a context is enabled. SX_i is incremented by 1 for every received 16-byte word, except when it equals BTE_CONTEXT_END_i[15:4] X. In that case it is reset to BTE_CONTEXT_START_i[15:7] X and SY_i is incremented. SY_i is reset when it reaches the bottom-right corner of the context.

Therefore, the BTE can only translate raster accesses:

- Image data must be provided line by line, starting from the top-left corner of the context.
- A line stride of 64KB is expected.
- The maximum supported image height is 8k lines.

Figure 8-80 is an example of an active context. There is only one location in an active context where an access from OCPI is expected (green). Accesses to any other location trigger an IRQ_CTXx_INVALID event. Reads to contexts in write mode (BTE_CONTEXT_CTRL_i[7:6] MODE = 0) or writes to contexts in read mode (BTE_CONTEXT_CTRL_i[7:6] MODE = 1) trigger an IRQ_CTXx_INVALID event. When an access to an expected location is received but the burst length exceeds the context end, an IRQ_CTXx_INVALID event is triggered.

Figure 8-80. ISS BTE Expected Access Locations in the Virtual Space

camss-322

Some alignment constraints are summarized as follows and are shown in Figure 8-81. They apply only to translated accesses.

- The context start addresses are aligned on 16-byte boundaries.
- The context width is aligned on 16-byte boundaries.
- The OCPI initiator must not use BYTEEN to qualify subwords in the middle of lines. The BTE interprets each BYTEEN as 0xFFFF. Access of partial words triggers an IRQ_CTXx_INVALID error.
- The line length sent by the initiator can be 1-byte aligned. The initiator can use BYTEEN to qualify valid data for the last access of the line. The BTE treats those accesses as full 16-byte writes and writes 0 data into its local buffers to complete the access. Those 0s are forwarded to OCPO when burst translation is performed. Software must ensure this data is discarded when the buffer is read back.
- The BTE does not impose any specific constraint on vertical alignment on the TILER tile and subtile grids. However, it is strongly recommended to configure the burst generation in such a way the requests performed to the TILER do not cross tile or subtile boundaries. For more information, see Section 8.2.7.3.2.5, ISS BTE TILER Space Accesses: 2D Burst Generation.
- The BTE accepts only one outstanding transaction per OCP tag on the OCPI port. When an initiator

tries to generate an OCP request on a tag ID that is already used (no response has been returned on OCPI), the OCPI port is stalled.

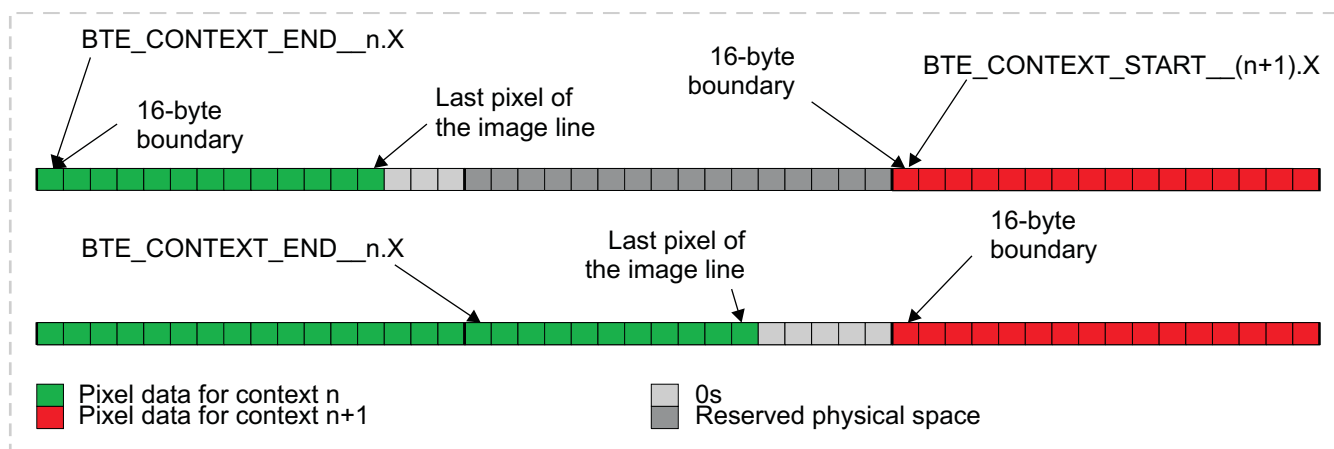

- The amount of memory allocated for each context must be a multiple of 512 bytes. Software must leave $\text{mod}(\text{BTE_CONTEXT_END}_i - \text{BTE_CONTEXT_START}_i + 1, 8)$ unused locations between the end of the context and the start of the next one. No accesses to this space from OCPI are allowed, but the BTE can use it to store data.
- While programming a BTE context, the BTE context End X value of all contexts must be less than $\text{MEMORY}/64$ in 128-bit address (equals $\text{MEMORY}/4$ in byte address)

NOTE: The generic BTE MEMORY size can be found by reading the [BTE_HL_HWINFO\[18:0\]](#) MEMORY bit field.

- While reading from a BTE-translated location, the CCP2 read burst size must be greater than or equal to (\geq) 16 bytes (128 bits) for correct operation. Bus width translation is performed in the ISS. Therefore, 64-bit accesses lead to 128-bit accesses with $\text{BYTEEN} = 0x00FF$. On the BTE side, BYTEEN is always processed as $0xFFFF$; thus, access to a BTE-translated 128-bit location is not correct if software uses 64-bit access.

Figure 8-81 shows the BTE context alignment constraints.

Figure 8-81. ISS BTE Context Alignment Constraints

camss-323

8.2.7.3.2.3 ISS BTE TILER Context Configuration Example

Global configuration and context configuration must be done before traffic from the master can be enabled.

This section provides a configuration example used to write YUV4:2:0 data into a 90-degree rotated buffer ($S = 1, Y = 1, X = 0$). The YUV frame is made up of two objects: Y data (8 bits) and UV data (16 bits).

The BTE provides data orientation and format information to the TILER using a 33-bit address. It can be controlled by software using the [BTE_CONTEXT_BASE_i](#) and [BTE_CONTEXT_CTRL_i\[12\]](#) ADDR32 bits. ADDR32 must be set to 1. Bits [31:27] of the address control the accessed view format. [Table 8-229](#) is an example of a BTE TILER context configuration.

Figure 8-82 shows BTE TILER mode addressing in 90- or 270-degree orientation.

Table 8-229. ISS BTE TILER Context Configuration Example

| 32 | 31 | 30 | 29 | 28 | 27 | 26 ... 4 | 3 ... 0 |
|----|-------------|----|----|------|----|-----------------|---------|
| T | Orientation | | | Mode | | Virtual Address | |
| 1 | S | /Y | /X | M1 | M0 | A26 ... A4 | 0 |

For the example described here, the following settings are used:

90-degree view, 8-bit data ADDR[32:27] = 0b1 110 00
 90-degree view, 16-bit data ADDR[32:27] = 0b1 110 01

Software must also configure the [BTE_CONTEXT_CTRL_i\[9:8\]](#) GRID bit field to match the view and format set by the base address:

90-degree view, 8-bit data GRID = 1 Stride = 8k
 90-degree view, 16-bit data GRID = 1 Stride = 8k

Figure 8-82. ISS BTE TILER Mode Addressing in 90- or 270-Degree Orientation

camss-701

Bits [26:0] of the [BTE_CONTEXT_BASE_i](#) register are used to address a pixel in the virtual space of TILER. It must point to the top-left corner of the 2D object.

Software must also configure the other context register before it can start it by setting the [BTE_CONTEXT_CTRL_i\[0\]](#) START bit.

8.2.7.3.2.4 ISS BTE Local Memory Management

8.2.7.3.2.4.1 ISS BTE Introduction

The amount of data buffered is defined by the [BTE_CONTEXT_CTRL_i\[29:16\]](#) TRIGGER bit field. In write mode, translated 2D writes to OCPO are issued when the buffer fill level is greater than or equal to the value of the [BTE_CONTEXT_CTRL_i\[29:16\]](#) TRIGGER bit field. In read mode, translated 2D reads are sent to OCPO when the buffer level is less than the value of the [BTE_CONTEXT_CTRL_i\[29:16\]](#) TRIGGER bit field.

8.2.7.3.2.4.2 ISS BTE Buffer Flushing

8.2.7.3.2.4.2.1 ISS BTE One-Shot Mode

One-shot mode is enabled by setting the [BTE_CONTEXT_CTRL_i\[10\]](#) ONESHOT bit.

During normal operation, a data transfer from local memory to the TILER is automatically triggered when sufficient data is available in the buffer.

Three lines of data remain in the buffer once the OCPI initiator stops sending data into the context.

The BTE supports two ways to flush data remaining in the buffer:

- The last data (bottom-right corner) in a context is written. The last data is defined by the [BTE_CONTEXT_END_i\[15:4\]](#) X and [BTE_CONTEXT_END_i\[28:16\]](#) Y bit fields.
- Software writes the [BTE_CONTEXT_CTRL_i\[2\]](#) FLUSH bit. This is typically done when the context has been stopped before the full frame has been written.

An autoflush mode controls automatic context flushing when an IDLE request is received. It can be activated by setting the [BTE_CONTEXT_CTRL_i\[11\]](#) AUTOFLUSH bit to 1.

During a context flush, all remaining data in the buffer are written to the TILER.

Buffer flushing has lower priority than burst translation active contexts or forwarding transparent accesses. This prevents performance degradation.

If software wants to abort context operation at a random location, it must disable the context.

8.2.7.3.2.4.2 ISS BTE Continuous Mode

When continuous mode is selected (the `BTE_CONTEXT_CTRL_i[10]` ONESHOT bit set to 0), reception of frame *n* pushes the data remaining from frame 1 out of the memory to OCPO. This mode is particularly useful when vertical blanking periods are too short to perform a buffer flush at the end of the frame. Also, it avoids creating traffic peaks due to buffer flushing.

The frame height must be a multiple of eight lines and the `BTE_CONTEXT_CTRL_i[14:13]` INITSY bit field must be 0x0 in continuous mode.

8.2.7.3.2.4.3 ISS BTE Buffer Prefetch

The buffer must be prefilled before read requests requiring translation can be accepted. Buffer prefetch starts with the top-left corner of the frame when a context is enabled by setting the `BTE_CONTEXT_CTRL_i[0]` START bit. When enough lines have been prefetched, an `IRQ_CTXx_DONE` event is triggered to inform software that the context is ready to perform request translation. Typically, software enables the data flow requiring translation in response to this event. Context ready for transaction and last transaction can be controlled by `BTE_CONTEXT_START` and `BTE_CONTEXT_END`, respectively.

When a read request requiring translation is received while prefetch is ongoing, an `IRQ_CTXx_ERR` event is triggered. It informs software that the read traffic was enabled too early. The BTE returns 0s to OCPI for the failing request (it does not hold the response until real data is available).

After prefetch completion, when a request requiring translation is received but the required data is missing (the BTE is waiting for a response from OCPO), the BTE delays the response on OCPI until the missing data is received on OCPI.

This behavior avoids stalling the OCPI port for too long (that is, a prefetch of up to 3.25 lines of data). However, it avoids getting errors because of slow OCPI responses.

8.2.7.3.2.4.4 ISS BTE Bandwidth Limiter

Translated and transparent traffic has higher priority than prefetch and flushing traffic. However, overall system bandwidth is limited. Requesting too much bandwidth for prefetch and flushing traffic may increase latencies for higher priority traffic. That could affect higher priority traffic.

Software can limit the speed of prefetching and buffer flushing by using the `BTE_CTRL[31:22]` `BW_LIMITER` bit field. Typically, this register is used to avoid the buffer prefetch and flush traffic using all the available system bandwidth. This register does not slow down the translated or transparent traffic.

The example in [Figure 8-83](#) assumes:

- 200-MHz functional clock
- 800 Mbps of transparent traffic = one 8 × 128-bit burst every 32 cycles

Without the bandwidth limiter, prefetch and flush traffic may use up to $3.2 \times 0.8 = 2.4$ Gbps. Using `BTE_CTRL[31:22]` `BW_LIMITER` = 24 ensures that at a maximum one flush/prefetch request is issued every 32 cycles. A prefetch/flush request may be delayed by higher priority traffic of OCP port stalls. To avoid excessive traffic slowdown, the BTE tries to catch up by requesting the next flush/prefetch transaction earlier.

Figure 8-83. BTE Bandwidth Limiter Example

camss-332

8.2.7.3.2.5 ISS BTE TILER Space Accesses: 2D Burst Generation

8.2.7.3.2.5.1 ISS BTE Buffer Fill Level

The BTE maintains an internal counter to keep track of the buffer fill level. This internal counter is used to detect when a translated OCP request is sent to the OCPO port. The counter also accounts for padding data. Figure 8-84 shows the BTE buffer fill-level padding.

Figure 8-84. ISS BTE Buffer Fill-Level Padding

camss-333

In BTE context, the preferred parameter is a 128-bit word as the unit. The `BTE_CONTEXT_START_i` and `BTE_CONTEXT_END_i` registers are usually written as byte-aligned; however, the `BTE_CONTEXT_START_i.X` and `BTE_CONTEXT_END_i.X` bit fields are more readily understood (nominally) as (128 bytes = 8 x 128 bits = 8 words).

The (lower half) `BTE_CONTEXT_END_i` register must be written as byte-aligned, but the `BTE_CONTEXT_END_i.X` bit field is understood (nominally) as (128 bits = 1 word).

The BTE TRIGGER is based on word size (128 bits), but the related (upper half) `BTE_CONTEXT_CTRL_i` register is not byte-aligned; it is word-aligned (128 bits).

$$LINE_LENGTH = ((BTE_CONTEXT_END_i[15:4] X) - BTE_CONTEXT_START_i[15:7] X) \& 0xFF8 + 8$$

NOTE: `LINE_LENGTH` is measured as a 128-bit word and can be used directly for TRIGGER calculation ($3 * LINE_LENGTH + x$)

Example 1: 64 x 15 pixels line = 64 x 15 Nb bytes in a line
 (Nb bytes in a line - 16(128-bit word)) 4 = 0x3B
`LINE_LENGTH` = (0x3B & 0xFF8) + 8 = 0x40
`TRIGGER` = 0x40 * 3 + 2 = 0xC2

Example 2: 64 x 11 pixel line = 64 x 11 Nb bytes in a line
 (Nb bytes in a line - 16(128-bit word)) 4 = 0x2B
`LINE_LENGTH` = (0x2B & 0xFF8) + 8 = 0x30
`TRIGGER` = 0x30 * 3 + 2 = 0x92

Figure 8-84 is a visual representation of the following explanation about how read or write events are triggered determined by the internal buffer size.

When context is started, the buffer fill level is initialized to $\text{LINE_LENGTH} \times \text{BTE_CONTEXT_CTRL_i}[14:13] \text{ INITSY} + \text{BTE_CONTEXT_CTRL_i}[15] \text{ INITSX}$ (see the previous equation for the LINE_LENGTH calculation). If the BTE reads or writes, the level of the internal buffer is incremented or decremented, respectively, by the burst size. Here, only full 16-byte accesses are performed. Other OCP BYTEEN patterns are forced to 0xFF.

The $\text{BTE_CONTEXT_CTRL_i}[29:16] \text{ TRIGGER}$ bit field triggers a buffer level read or write even. In write mode, if flushing, the data level is greater than 0; if not flushing, the BTE translates to OCPO when the level is greater than or equal to the value set by the register. If the level is smaller than the $\text{BTE_CONTEXT_CTRL_i}[29:16] \text{ TRIGGER}$ software setup, then the BTE reads data.

8.2.7.3.2.5.2 ISS BTE OCP Request Generation

Except on borders:

- TILER bursts are 32 bytes \times 4 lines of data blocks.
- Bursts are aligned on subtile boundaries.

The BTE maintains an internal 2D pointer (DX_i, DY_i) that corresponds to the top-left corner of the next access to be issued to the TILER. It is initialized to (0, 0) when a context is enabled or wraps around. It is updated each time an access to the TILER is performed.

[Table 8-230](#) lists all supported TILER formats and views.

Table 8-230. ISS BTE Supported TILER Formats and Views

| Modes | View | | | Description | OFST | Subtile Grid | | 1KB Tile Grid | | X | | Y | | GRID | Subtile Aligned | | Tile Aligned | |
|--------|------|----|----|---------------------------------------|-------|--------------|---|---------------|----|-----|-----|-----|-----|------|-----------------|---------|--------------|---------|
| | S | /Y | /X | | | X | Y | X | Y | LSB | MSB | LSB | MSB | | X | Y | X | Y |
| | | | | | | | | | | | | | | | | | | |
| 8-bit | 0 | 0 | 0 | 0-degree view | 16384 | 4 | 4 | 32 | 32 | 0 | 13 | 14 | 26 | 0 | [1:0] | [15:14] | [4:0] | [18:14] |
| | 0 | 0 | 1 | 0-degree view with vertical mirror | | | | | | | | | | | | | | |
| | 0 | 1 | 0 | 0-degree view with horizontal mirror | | | | | | | | | | | | | | |
| | 0 | 1 | 1 | 180-degree view | | | | | | | | | | | | | | |
| | 1 | 0 | 0 | 90-degree view with vertical mirror | 8192 | 4 | 4 | 32 | 32 | 0 | 12 | 13 | 26 | 1 | [1:0] | [14:13] | [4:0] | [17:13] |
| | 1 | 0 | 1 | 270-degree view | | | | | | | | | | | | | | |
| | 1 | 1 | 0 | 90-degree view | | | | | | | | | | | | | | |
| | 1 | 1 | 1 | 90-degree view with horizontal mirror | | | | | | | | | | | | | | |
| 16-bit | 0 | 0 | 0 | 0-degree view | 32768 | 8 | 2 | 64 | 16 | 0 | 14 | 15 | 26 | 2 | [2:0] | [15] | [5:0] | [18:15] |
| | 0 | 0 | 1 | 0-degree view with vertical mirror | | | | | | | | | | | | | | |
| | 0 | 1 | 0 | 0-degree view with horizontal mirror | | | | | | | | | | | | | | |
| | 0 | 1 | 1 | 180-degree view | | | | | | | | | | | | | | |
| | 1 | 0 | 0 | 90-degree view with vertical mirror | 8192 | 4 | 4 | 32 | 32 | 0 | 12 | 13 | 26 | 1 | [1:0] | [14:13] | [4:0] | [17:13] |
| | 1 | 0 | 1 | 270-degree view | | | | | | | | | | | | | | |
| | 1 | 1 | 0 | 90-degree view | | | | | | | | | | | | | | |
| | 1 | 1 | 1 | 90-degree view with horizontal mirror | | | | | | | | | | | | | | |
| 32-bit | 0 | 0 | 0 | 0-degree view | 32768 | 8 | 2 | 64 | 16 | 0 | 14 | 15 | 26 | 2 | [2:0] | [15] | [5:0] | [18:15] |
| | 0 | 0 | 1 | 0-degree view with vertical mirror | | | | | | | | | | | | | | |
| | 0 | 1 | 0 | 0-degree view with horizontal mirror | | | | | | | | | | | | | | |
| | 0 | 1 | 1 | 180-degree view | | | | | | | | | | | | | | |
| | 1 | 0 | 0 | 90-degree view with vertical mirror | 16384 | 8 | 2 | 64 | 16 | 0 | 13 | 14 | 26 | 3 | [2:0] | [14] | [5:0] | [17:14] |
| | 1 | 0 | 1 | 270-degree view | | | | | | | | | | | | | | |
| | 1 | 1 | 0 | 90-degree view | | | | | | | | | | | | | | |
| | 1 | 1 | 1 | 90-degree view with horizontal mirror | | | | | | | | | | | | | | |

The `BTE_CONTEXT_BASE_i` and `BTE_CONTEXT_CTRL_i[9:8]` GRID registers must be configured by software to choose the format and view. The format must match the data stored into the virtual space. The choice of the view depends on the desired behavior.

The GRID bit field controls the used OCP stride and OCP address generation. The OCP address is generated using the following formula:

$$\text{OCP_ADDR} = \text{BTE_CONTEXT_BASE_n} + \text{DX_x} + \text{DY_x} \ll \text{Y_LSB}$$

`Y_LSB` corresponds to the Y LSB column of [Table 8-230](#).

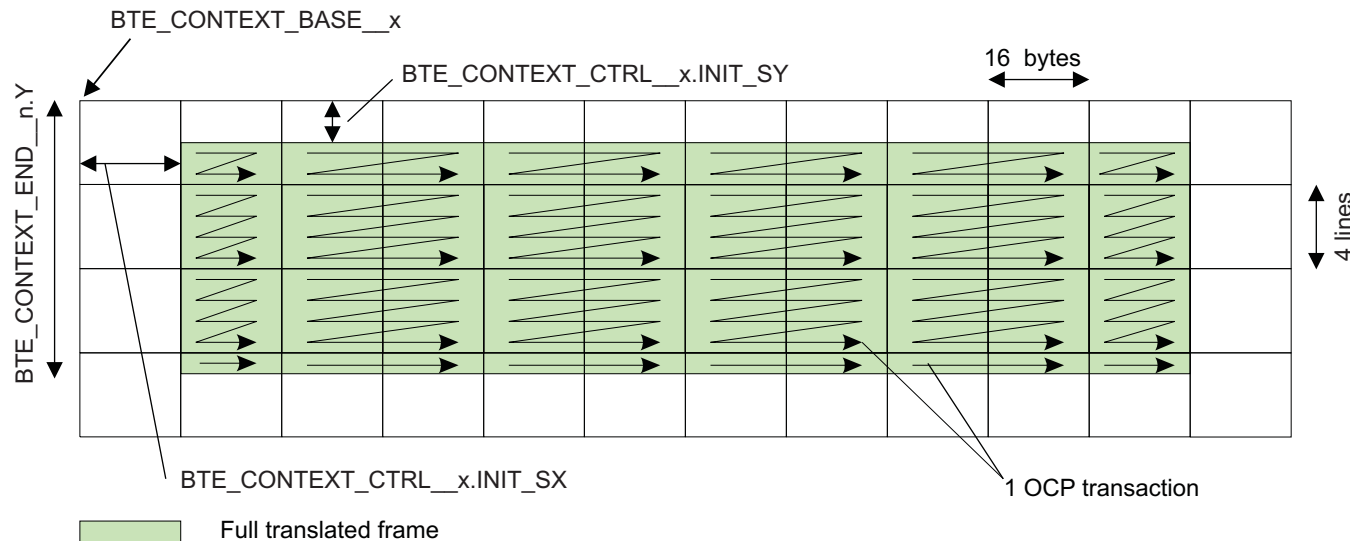

The OCP stride corresponds to the OFST column of [Table 8-230](#). The tile and subtile grid information is currently not used by hardware.

The BTE does not automatically realign 2D bursts on tile or subtile boundaries. However, software can force the $(\text{SX}_i, \text{SY}_i)$ (see [Section 8.2.7.3.2.4, ISS BTE Local Memory Management](#), for the definition of SY_i) reset value to be used. It is set through the `BTE_CONTEXT_CTRL_i[15]` `INITSX` bit and the `BTE_CONTEXT_CTRL_i[14:13]` `INITSY` bit field.

The length and height of the 2D burst is adapted by the BTE to avoid sending dummy data to the TILER.

[Figure 8-85](#) is an example of BTE 2D burst generation. The vertical start and end of the full 2D frame are not vertically aligned on the grid.

Figure 8-85. ISS BTE 2D Burst Generation

camss-336

8.2.7.3.2.6 ISS BTE Posted and Nonposted Write Support

The BTE can handle posted and nonposted writes received on OCPI. Normally, only nonposted writes should be used.

For transparent accesses, posted and nonposted writes are forwarded to OCPO. The response provided by OCPO is returned to OCPI.

For translated accesses, the response to posted and nonposted writes is provided by the BTE. It does not wait for the response of the translated request that is sent to the TILER. In other words, the BTE has no true nonposted write support for translated accesses. The BTE does not ensure that the data has effectively been written to the destination memory when it returns the response to a nonposted translated write.

True nonposted write support is ensured for transparent accesses. Only nonposted writes must be used. Select nonposted write mode through the [BTE_CTRL\[5\] POSTED](#) bit.

8.2.7.3.2.7 ISS BTE Error Reporting

Unexpected accesses are flagged using interrupts. Also, when an SResp = ERR is received on OCPO, an interrupt is triggered. If the response corresponds to a transparent access, it is forwarded to OCPI.

The BTE is not an OCP checker: It expects only valid and supported transactions from the external world.

Also, it is not intended to detect all types of software errors; few cases are detected. Those cases are described in the functional description sections.

8.2.7.3.2.8 ISS BTE Interrupts

All events generated by the module are merged into a single event at ISS level. This event can be enabled from ISS level by the [ISS_HL_IRQENABLE_SET_j\[11\] BTE_IRQ](#) bit. [Table 8-231](#) lists the BTE interrupt events.

Table 8-231. ISS BTE Interrupt Events

| Event | Description |
|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IRQ_OCP_ERR | OCP error received from OCPO master port |
| IRQ_INVALID | An access to a location that is not mapped to any context has been performed. For more information, see Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| IRQ_CTXx_DONE | Context has been fully transferred to the TILER. This interrupt is triggered when flushing completes in one-shot mode. It is triggered once per frame in continuous mode. |
| IRQ_CTXx_INVALID | Unexpected address sequence or access direction (read of a context in write mode or write of a context in read mode). For more information, see Section 8.2.7.3.2.2, ISS BTE Virtual Address Space and Context Mapping . |
| IRQ_CTXx_ERR | Can occur only when a context is configured in read mode. This request triggers when a read request is received but insufficient data is buffered to perform the translation. For more information, see Section 8.2.7.3.2.4.3, ISS BTE Buffer Prefetch . |

8.2.7.3.2.9 ISS BTE Debug Support

The BTE has no specific debug support.

8.2.7.4 ISS BTE Programming Model

8.2.7.4.1 ISS BTE Reset

The BTE can accept a general software reset, propagated through all the hierarchy. This reset can be done to initialize the module and has the same effect as the hardware reset.

1. Set the [BTE_HL_SYSCONFIG\[0\] SOFTRESET](#) bit to 1.
2. Read the [BTE_HL_SYSCONFIG\[0\] SOFTRESET](#) bit to check whether it is set to 1, which means the reset occurred.

If after five reads, the [BTE_HL_SYSCONFIG\[0\] SOFTRESET](#) bit still returns 0, assume that an error occurred during the reset stage.

Programmers must not set the [BTE_HL_SYSCONFIG\[0\] SOFTRESET](#) bit to 1 if the BTE is integrated in a subsystem; it is safer to use the software reset at subsystem level.

NOTE: A software reset does not reset the IDLE protocol signals.

8.2.7.4.2 ISS BTE Interrupts

All events are mapped to a single interrupt output, BTE_IRQ. [Table 8-232](#) lists the procedure to configure or manage the BTE interrupts.

Table 8-232. ISS BTE Configure/Manage Interrupts

| Step | Bit Field | Value |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|-------|
| Each event that generates an interrupt can be individually enabled by setting the appropriate bit. | BTE_HL_IRQENABLE_SET | |
| Each event that generates an interrupt can be individually disabled by setting the adequate bit. | BTE_HL_IRQENABLE_CLR | |
| When an event occurs, the corresponding bit in the BTE_HL_IRQSTATUS_RAW register is set, regardless of whether or not the event is enabled. Bits in the BTE_HL_IRQSTATUS registers are set only when an enabled event occurs. | BTE_HL_IRQSTATUS_RAW and BTE_HL_IRQSTATUS | |
| Software can clear a pending event by setting the adequate bit in the BTE_HL_IRQSTATUS register. | BTE_HL_IRQSTATUS | |

8.2.7.4.3 ISS BTE Context Configuration

Global configuration and context configuration must be done before traffic from the master can be enabled.

This section provides a configuration example used to write YUV4:2:0 data into a 90-degree rotated buffer (S = 1, Y = 1, X = 0). The YUV frame consists of two objects: Y data (8 bits) and UV data (16 bits).

The BTE provides data orientation and format information to the TILER using a 33-bit address. It can be controlled by software using the [BTE_CONTEXT_BASE_i](#) and [BTE_CONTEXT_CTRL_i\[12\]](#) ADDR32 registers.

ADDR32 must be set to 1. Bits [31:27] of the address control the accessed view and data format. [Table 8-233](#) gives the format of the TILER address. [Figure 8-86](#) shows BTE tiled mode addressing in 90- or 270-degree orientation.

Table 8-. TILER Address Format

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|-------------|----|------|----|-----------------|------------|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|--|--|--|--|
| 32 | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | | | |
| T | Orientation | | Mode | | Virtual Address | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
| 1 | S | ▷ | ⊗ | M1 | M0 | A26 ... A4 | | | | | | | | | | | | | | | | | | | | | | | | | | 0 | | | | |

For the example described here, the following settings are used.

- 90-degree view, 8-bit data ADDR[32:27] = 0b1 110 00
- 90-degree view, 16-bit data ADDR[32:27] = 0b1 110 01

Software must also configure the [BTE_CONTEXT_CTRL_i\[9:8\]](#) GRID bit field to match the view and format set by the base address:

- 90-degree view, 8-bit data GRID = 1 Stride = 8k
- 90-degree view, 16-bit data GRID = 1 Stride = 8k

Figure 8-86. ISS BTE Tiled Mode Addressing in 90- or 270-Degree Orientation (S = 1)

camss-340

Bits [26:0] of the [BTE_CONTEXT_BASE_i](#) register are used to address a pixel in the virtual space of the TILER. It must point to the top-left corner of the 2D object.

Software must also configure the other context registers before it can start it by setting the [BTE_CONTEXT_CTRL_i\[0\]](#) START bit.

8.2.7.4.4 ISS BTE Change Context Configuration

All contexts operate independently. Software can change the configuration of an inactive context while other contexts are active and perform request translation.

When software must change the configuration of an active context, it must follow the sequence in [Table 8-234](#).

Table 8-234. ISS BTE Change Context Configuration

| Step | Bit Field | Value |
|------|-----------|-----------------------------------------------------------------------------------------------|
| 1 | | Ensure that the initiator does not send any more data to this context until it is re-enabled. |

Table 8-234. ISS BTE Change Context Configuration (continued)

| Step | Bit Field | Value |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|----------|
| Disable the context. <ul style="list-style-type: none"> The STOP condition is considered on a valid OCP boundary. It preserves the internal states so that buffer flushing can be done. The BTE no longer translates requests received for this context. Any transactions received for an inactive context trigger error interrupts. The BTE completes all outstanding transactions on OCPO. | BTE_CONTEXT_CTRL_i[1] STOP | 0x1 |
| Flush all remaining data for the context, if needed. If software simply wants to abort the transfer to recover from some error condition, flushing is not needed. The context is automatically reset when it is enabled again. | BTE_CONTEXT_CTRL_i[2] FLUSH | 0x1 |
| Wait until the context completes pending OCP transaction and buffer flush (if enabled). It sets the IRQ_CTXx_DONE when it becomes idle. | BTE_HL_IRQSTATUS . IRQ_CTXx_DONE | Read 0x0 |
| Change the context configuration. | | |
| Enable the context by setting the BTE_CONTEXT_CTRL_i[0] START bit. Setting the START bit resets the internal state-machine of the context. | BTE_CONTEXT_CTRL_i[0] START | 0x1 |

Alternatively, software can change the context mode to one-shot and wait until the [CTXx_DONE_IRQ](#) is triggered.

NOTE: Once a context is disabled it cannot be resumed simply by writing the START bit. In fact, doing so resets the internal FSM. If data is lost in the buffer, it will be lost.

8.2.8 ISS CBUFF

8.2.8.1 ISS CBUFF Environment

There are no particular environment attributes. See [Section 8.2.2](#), *ISS Interfaces Environment*.

8.2.8.2 ISS CBUFF Integration

[Figure 8-87](#) shows the integration of the CBUFF in the ISS. Because the CBUFF maps a virtual memory space from the physical memory, it therefore communicates with the ISS ISP and ISS interface modules for data to and from memory. This figure shows the normal data flow for further processing by the ISP and/or still-image coprocessor (SIMCOP) (in green) and the stall functionality of CBUFF (in red), which stall the data for a certain amount of time. An example of stalling is when the ISP processes the data faster than the input from CCP2 to memory. The CBUFF then must stall the data flow until a sufficient amount of data can be read from memory by the ISP.

Figure 8-87. ISS CBUFF Integration

RED - Stalled data flow
GREEN - Normal data flow

camss-679

For power domain, clocks, reset, and hardware requests, see [Section 8.1.2.4, ISS Power Management](#).

8.2.8.2.1 ISS CBUFF PRCM Interface

8.2.8.2.1.1 ISS CBUFF Reset and Idle Mechanism

A reset signal is provided by the PRCM module to the top-level ISS power and clock-management module.

For standby, when none of the ISS modules require CBUFF execution actions, ISS PM executes the standby sequence, which reaches the CBUFF. When an IDLE request arrives, the CBUFF data is drained. After all transactions are drained, the CBUFF acknowledges the IDLE request to the ISS PM/CM. The IDLE request/acknowledge steps are:

When an IDLE request is received in smart-idle mode:

1. CBUFF stops accepting any new OCP requests on a clean OCP transaction boundary.
2. Waits until the interrupt output becomes inactive (no more enabled event pending)
3. Waits until all outstanding OCP transactions are complete on OCPO and OCPI. CBUFF keeps track of issued requests, data phases, and responses for that purpose.
4. CBUFF disconnects the OCPO port.
5. CBUFF acknowledges the IDLE request.

When a wake-up request is received in smart-idle mode:

1. CBUFF connects the OCPO port.
2. Starts accepting new requests from OCPI
3. Acknowledges the functional state

Idle mode is controlled through the [CBUFF_HL_SYSCONFIG\[3:2\]](#) IDLEMODE bit field. For software reset, it is recommended to use the global ISS reset; if a reset is required, it can be set from the [CBUFF_HL_SYSCONFIG\[0\]](#) SOFTRESET bit.

8.2.8.2.2 ISS CBUFF Interrupts

All events generated by the module are merged into a single event at ISS level. This event can be mapped to the MPU subsystem by enabling the [ISS_HL_IRQENABLE_SET_i\[10\]](#) CBUFF_IRQ bit. [Table 8-263](#) lists the procedure to manage CBUFF interrupts.

Table 8-263. ISS CBUFF Interrupt Management

| Description | Bit Field | Value |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------|-------|
| Each event that generates an interrupt can be individually enabled by setting the appropriate bit. | CBUFF_HL_IRQENABLE_SET | |
| Each event that generates an interrupt can be individually disabled by setting the appropriate bit. | CBUFF_HL_IRQENABLE_CLR | |
| When an event occurs, the corresponding bit in the CBUFF_HL_IRQSTATUS_RAW register is set regardless of whether or not the event is enabled. Bits in the CBUFF_HL_IRQSTATUS registers are only set only when an enabled event occurs | CBUFF_HL_IRQSTATUS_RAW and CBUFF_HL_IRQSTATUS | |
| Software can clear a pending event by setting the appropriate bit in the CBUFF_HL_IRQSTATUS register. | CBUFF_HL_IRQSTATUS | |

The CBUFF can generate three events per context and one global event. All events are merged into one physical interrupt line. [Table 8-264](#) describes the CBUFF-generated events.

Table 8-264. ISS CBUFF-Generated Events

| Event | Description |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| IRQ_CTXx_READY | Read mode: CPU can write data to the physical window pointed by CBUFF_CTX_STATUS_i[3:0] WB. |
| | Write mode: CPU can read data from the physical window pointed by CBUFF_CTX_STATUS_i[3:0] WB. |
| | Read/write mode: The OCPI initiator has completed writing a physical window. |
| IRQ_CTXx_INVALID | Invalid access |
| | OCPI writes the virtual space of context i in read mode. |
| | OCPI reads the virtual space of context i in write mode. |
| | OCPI writes the virtual space of context i outside the CBUFF_CTX_STATUS_i[11:8] WA window in write or read/write mode. |

Table 8-264. ISS CBUFF-Generated Events (continued)

| Event | Description |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | OCPI reads the virtual space of context i outside the <code>CBUFF_CTX_STATUS_i[11:8]</code> WA window in read mode. |
| | OCPI reads the virtual space of context i outside the <code>CBUFF_CTX_STATUS_i[3:0]</code> WB window in read/write mode. |
| | CPU writes the DONE bit when physical windows are not ready for the CPU. |
| | This event indicates a wrong configuration of the CBUFF, the OCPI initiator or bogus software. When it happens, context i goes into an error state. In this state all accesses to the virtual space of context i are cancelled: they are not forwarded to the physical space. The purpose is to prevent corruption of the physical memory. Of course, the CBUFF still returns OCP responses to OCPI to ensure the integrity of the OCP. |
| | The error state can be left by disabling the context i and re-enabling it. Before doing so, software must ensure that there are no more outstanding requests to the virtual space of context i. |
| IRQ_CTXx_OVR | Physical space overflow or underflow event This event indicates a bandwidth mismatch between data producer and data consumer. When it happens, context i does not go into error state. However, the data in the physical space is likely to be corrupted. |
| IRQ_OCP_ERR | OCP error received in the OCPO master port. The OCP response is forwarded to OCPI normally. |

8.2.8.3 ISS CBUFF Functional Description

The CBUFF maps a virtual space to a physical space by address translation. It does not change the data or store it locally.

8.2.8.3.1 ISS CBUFF Features

The ISS CBUFF features are:

- Fully transparent for accesses out of the configured virtual space
- Three functional modes:
 - Read mode: Read requests received from OCPI and forwarded after translation to OCPO. Writes are handled by an external process and acknowledged by the CPU.
 - Write mode: Write request received from OCPI and forwarded after translation to OCPO. Reads are handled by an external process and acknowledged by the CPU.
 - Read/write mode: Read and write requests received from OCPI and forwarded after translation to OCPO
- Four independent contexts
- Virtual address space (linear) mapped into a physical space (circular)
- Maximum physical buffer size of 16 × 16MB:
 - Physical space consists of 2, 4, 8, or 16 windows.
 - Maximum allowed window size is 16MB.
- Support of 2D addressing modes
- Strong error detection mechanisms to prevent data corruption caused by bogus configuration
- Addresses are 128-bit aligned, but window fill level managing is byte accurate
- Bandwidth control feedback loop to stall in initiator connected to OCPI

8.2.8.3.2 ISS CBUFF Functional Description

The CBUFF maps a virtual address space to a physical space also called circular buffer.

The CBUFF can handle up to eight contexts. For most data formats, primarily four contexts are used. In cases where YUV4:2:0 data is exchanged, two contexts are consumed by the SIMCOP (JPEG encode) coming from the resizer module, which is the ISP output module. Moreover, a context is a virtual full-frame buffer that maps to a configurable number of physical windows.

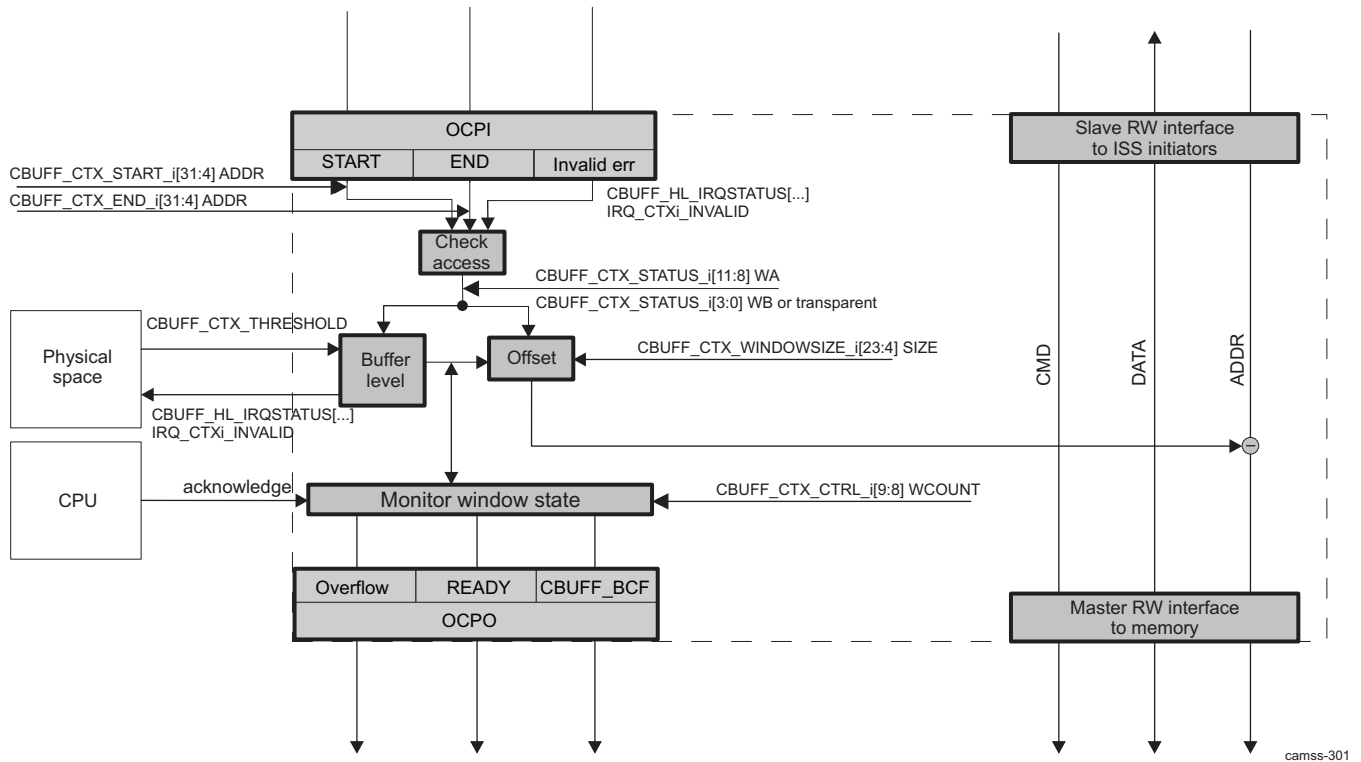

This section gives an overview of typical uses of the CBUFF.

8.2.8.3.2.1 ISS CBUFF Top-Level Diagram

Figure 8-88 shows the functional principle diagram. It does not include an exhaustive list of the interface signals or internal status registers.

A more detailed functional description is provided in the following sections.

Figure 8-88. ISS CBUFF Top-Level Diagram

camss-301

8.2.8.3.2.2 ISS CBUFF Functional Modes

The CBUFF supports three functional modes (see Table 8-265).

Table 8-265. ISS CBUFF Functional Modes

| Mode | Data Written by | Data Read by |
|-----------------|------------------------|------------------------|
| Write mode | ISS initiator | CPU-controlled process |
| Read mode | CPU-controlled process | ISS initiator |
| Read/write mode | ISS initiator | ISS initiator |

8.2.8.3.2.2.1 ISS CBUFF Write Mode

In write mode, the physical space is written by the CBUFF and it is read by the CPU. An IRQ_CTXx_READY event is set each time a physical window is available to be read by the CPU. This happens when the CBUFF_CTX_STATUS_i[11:8] WA pointer is moved by the CBUFF.

The CBUFF sets an IRQ_CTXx_READY event to inform the CPU that it can access the CBUFF_CTX_STATUS_i[3:0] WB physical window. The CBUFF cannot monitor CPU accesses to the physical window. The CPU must indicate when it has completed the processing of the CBUFF_CTX_STATUS_i[3:0] WB window by setting the CBUFF_CTX_CTRL_i[2:1] DONE bit field. This increments the window index CBUFF_CTX_STATUS_i[3:0] WB by one modulo the window count (defined by the CBUFF_CTX_CTRL_i[9:8] WCOUNT bit field).

The CBUFF ensures that one `IRQ_CTXx_READY` event is sent to the CPU per physical window to be read. In other words, when a new `IRQ_CTXx_READY` event occurs before the previous one(s) is acknowledged by the CPU, it is not lost. The CBUFF memorizes the event and triggers the interrupt line again when the CPU clears it.

When the CPU reads the physical space too slowly, the `CBUFF_CTX_STATUS_i[11:8]` WA window pointer falls into the `CBUFF_CTX_STATUS_i[3:0]` WB window. This generates an `IRQ_CTXx_OVR` event when the OCPI initiator performs an access to that window. The CPU receives the `IRQ_CTXx_READY` event only if it is allowed to access a physical window. Therefore, it cannot generate an `IRQ_CTXx_OVR` event in a normal case. The OCPI initiator accesses are tracked based on activity on the OCP port.

When an `IRQ_CTXx_OVR` event occurs, the buffer content is likely to be corrupted. However, the CBUFF context continues processing data normally; it does not go into error state. Software must reset data generation and the CBUFF in a clean manner.

Figure 8-89 shows an example scenario with `CBUFF_CTX_CTRL_i[9:8]` `WCOUNT = 1` (four windows). In normal operation, the CPU processes data at least at the same speed as it is written to the physical space. When this is not true, the number of windows to be read by the CPU increases. When no more physical windows are available for OCPI writes, an overflow occurs.

In the previous example, the CPU takes more time than expected to read the third buffer. Therefore, physical windows are not freed up. The OCPI initiator continues to write data into the physical window. That leads to an overflow when the OCPI initiator writes into the physical window that is read by the CPU (`CBUFF_CTX_STATUS_i[11:8]` WA = `CBUFF_CTX_STATUS_i[3:0]` WB and writes into `CBUFF_CTX_STATUS_i[11:8]` WA detected).

Figure 8-89. ISS CBUFF Write Mode CPU Interaction Example

- (1) When there is no physical window available to be read by the CPU and the CPU writes the DONE bit, an `IRQ_CTXx_INVALID` event occurs.
- (2) The bandwidth control feedback (BCF) feature can be used to prevent overflow. It must be supported by the module writing data into the virtual space (typically, an ISS).

8.2.8.3.2.2 ISS CBUFF Read Mode

In read mode, the physical space is read by the CBUFF and it is written by the CPU. An `IRQ_CTXx_READY` event is set each time a physical window is available to be written by the CPU. This is true until all free buffers are used.

The CBUFF sets an `IRQ_CTXx_READY` event to inform the CPU that it can write the `CBUFF_CTX_STATUS_i[3:0]` WB window. The CBUFF cannot monitor CPU accesses to the physical space. It must indicate when it completes writing the `CBUFF_CTX_STATUS_i[3:0]` WB window by setting the `CBUFF_CTX_CTRL_i[2:1]` DONE bit field. This increments the CPU window index `CBUFF_CTX_STATUS_i[3:0]` WB by one modulo the window count (defined by the `CBUFF_CTX_CTRL_i[9:8]` `WCOUNT` bit field).

The CBUFF ensures that one `IRQ_CTXx_READY` event is sent to the CPU per physical window to be written. In other words, when a new `IRQ_CTXx_READY` event occurs before the previous one(s) is acknowledged by the CPU, it is not lost. The CBUFF memorizes the event and triggers the interrupt line again when the CPU clears it.

The following is an example of a normal operation in which the CPU writes data faster than it is read by the OCPI initiator. [Figure 8-90](#) uses two physical windows (CBUFF_CTX_CTRL_i[9:8] WCOUNT = 0).

Figure 8-90. ISS CBUFF CPU Writes Data Faster Than it Is Read by the OCPI Initiator

Software must enable the ISS initiator only when at least one window is written by the CPU. Otherwise, an OVERFLOW event occurs when BCF is not used.

The CPU receives an interrupt each time a physical window is available to receive data. It clears the interrupt and then starts filling the physical window. When the buffer is completely written, it sets the CBUFF_CTX_CTRL_i[2:1] DONE bit field. This happens before the OCPI initiator has read all data from the previous physical window: the CPU must wait until the next IRQ_CTXx_READY event is received before it can write again to the physical space.

When the CPU writes buffers too slowly, the CBUFF_CTX_STATUS_i[11:8] WA window falls into the CBUFF_CTX_STATUS_i[3:0] WB window. This generates an IRQ_CTXx_OVR event only when the OCPI initiator performs reads to that window. The CPU receives the IRQ_CTXx_READY event only if it is allowed to access a physical window. Therefore, it does not generate an IRQ_CTXx_OVR event in a normal case. ISS accesses are tracked based on activity on the OCPI port.

When no buffer is available to be written by the CPU and the CPU writes the DONE bit, an IRQ_CTXx_INVALID event occurs.

When an IRQ_CTXx_OVR event occurs, the OCPI initiator reading the virtual space is likely to receive dummy data. However, the CBUFF context continues to process data normally; it does not go into error state. Software must reset the data consumer (OCPI initiator) and CBUFF context in a clean manner.

[Figure 8-91](#) is an example of CBUFF read mode CPU interaction.

Figure 8-91. CBUFF Read Mode CPU Interaction Example

The BCF feature can be used to prevent overflow. It must be supported by the module reading data from the virtual space (typically, an ISS).

8.2.8.3.2.2.3 ISS CBUFF Read/Write Mode

Reads and writes are performed by OPCI initiators such as a camera interface, ISP, or SIMCOP. Address translation is performed for read and write data flows. The WA pointer is used for the write data flow, and the WB pointer is used for the read data flow. Therefore, address translation for the write data flow is the same as for write mode.

In this mode, the OPCI read data flow is stalled when there is not enough data to read in the physical space. A typical application is to store data from the camera in a CBUFF and to read it back by the ISP. When the camera is slower than the ISP, the ISP stalls.

This mode does not rely on CPU synchronization. Synchronization is always performed using the BCF hardware mechanism. IRQ_CTXx_READY events are triggered in this mode when the OPCI write initiator has filled a physical window. Software can use this event for debug or performance bench marking purposes. Writes to the CBUFF_CTX_CTRL_i[2:1] DONE bit field are ignored in this mode.

The IRQ_CTXx_OVR event is triggered when an underflow occurs. In a normal case this should not occur, because the BCF signal is used to stall the read data flow when insufficient data is available in the physical space.

Figure 8-92 assumes:

- Read/write mode
- Four physical windows
- CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i
- The OPCI read initiator is faster than the OPCI write initiator. The BCF feature is used to stall the read initiator. CBUFF_CTX_CTRL_i[7:4] BCF = 2

Figure 8-92. ISS CBUFF Read/Write Mode Example

camss-305

8.2.8.3.2.3 ISS CBUFF Events and Status Checking

8.2.8.3.2.3.1 ISS CBUFF Operations

A CBUFFx_READY_IRQ event is generated each time the CPU can read data from the CBUFF. The CPU can clear the event when it starts processing the data to avoid masking other events. The CPU can keep track of the location on the data internally or use the CBUFF registers to compute it.

The formula used is: ADDR = CBUFF_CTX_STATUS_i[3:0] WB CBUFF_CTX_WINDOWSIZE_i + CBUFF_CTX_PHY_i

When the CPU is done with processing, it must free the buffer by setting the CBUFF_CTX_CTRL_i[10] DONE bit. Otherwise, an overflow event may occur.

The CBUFF does not keep track of EOF events. They must be managed by the CPU using the EOF event of the module that writes into the CBUFF. At the EOF, data may remain in the current write windows. For example, when the window size is set to 8 lines and the image size is 20 lines, only two window-ready events are generated for a linear addressing scheme. The remaining four lines can be read after the EOF event.

No automatic reset of the CBUFF FSM occurs at the end of the image frame. Software must reset the context by clearing the [CBUFF_CTX_CTRL_i\[0\] ENABLEABLE](#) bit when the frame is completely processed. A new frame can start only when the [CBUFF_CTX_CTRL_i\[0\] ENABLEABLE](#) bit is set.

8.2.8.3.2.3.2 ISS CBUFF Status Checking

The CBUFF provides read-only access to the [CBUFF_CTX_STATUS_i\[11:8\]](#) WA and [CBUFF_CTX_STATUS_i\[3:0\]](#) WB pointers through the [CBUFF_CTX_STATUS_i](#) register. For example, the [CBUFF_CTX_STATUS_i\[3:0\]](#) WB index can be used by the CPU to compute the address of a physical window. Those indexes can also be used to evaluate latency margins.

8.2.8.3.2.3.3 ISS CBUFF Register Accessibility During Frame Processing

All registers are busy-writeable registers. These registers/fields can be read or written even if the module is busy. Changes to the underlying settings occur instantly. However, module behavior is unpredictable when registers are changed during processing.

For correct operation, software must:

1. Disable all accesses to the virtual space managed by the context.
2. Disable the context by clearing the [CBUFF_CTX_CTRL_i\[0\] ENABLEABLE](#) bit.
3. Change the configuration.
4. Re-enable CBUFFx by setting the [CBUFF_CTX_CTRL_i\[0\] ENABLEABLE](#) bit.

8.2.8.3.2.4 ISS CBUFF Memory-to-Memory Operation BCF

The BCF mechanism matches the bandwidth between two processes.

The BCF feature can be used in all three CBUFF modes:

- Read mode: A CPU-controlled process writes data into physical space. The BCF signal is deasserted when the physical space contains enough data to start the read initiator connected to OCPI.
- Write mode: The BCF signal controls the write initiator connected to OCPI. When the CPU-controlled process does not read the data fast enough from the physical space, the BCF signal is asserted to stall filling of the buffer. It is deasserted when enough space is available in the physical space.
- Read/write mode: The BCF signal controls the read initiator connected to OCPI. Another initiator connected to OCPI fills the physical space. The BCF signal is deasserted when the physical space contains data that can be read by the read initiator. It is deasserted when insufficient data is available in the physical space.

The CBUFF_BCF output is controlled based on two factors:

- The window count available for the OCPI initiator to read/write
- The amount of data in the last available window (pretrigger)

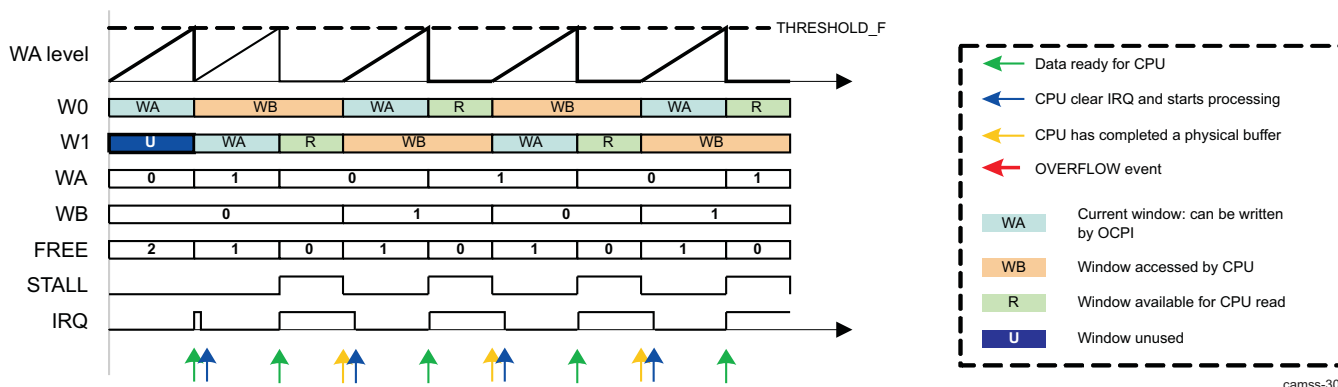

The CBUFF_BCF signal is enabled by the [CBUFF_CTX_CTRL_i\[7:4\]](#) BCF bit field. It defines:

- Write mode: The amount of required free windows to allow writing from the ISS. In other words, when less than the required amount of BCF windows is available for ISS writes, the stall mechanism is triggered. The number of free windows is initialized to the total window count of the context. It is decreased by 1 each time the OCPI initiator finishes writing a window. It is increased by 1 each time the CPU finishes reading a window.
- Read and read/write modes: The minimum amount of required full windows to allow reading from the OCPI. When fewer than [CBUFF_CTX_CTRL_i\[7:4\]](#) BCF windows are available for ISS read, the stall mechanism is triggered. The number of full windows is initialized to 0. It is decreased by 1 each time the OCPI initiator completes reading a window. It is increased by 1 each time the CPU/OCPI initiator finishes writing a window.

Figure 8-93 is an example of BCF use. It assumes:

- Write mode: OCPI writes data into physical space and the CPU reads it.
- Two physical windows
- $CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i$
- The OCPI write initiator is faster than the CPU.
- $CBUFF_CTX_CTRL_i[7:4] BCF = 1$

Figure 8-93. ISS CBUF Write Mode CPU Interaction Example BCF Used

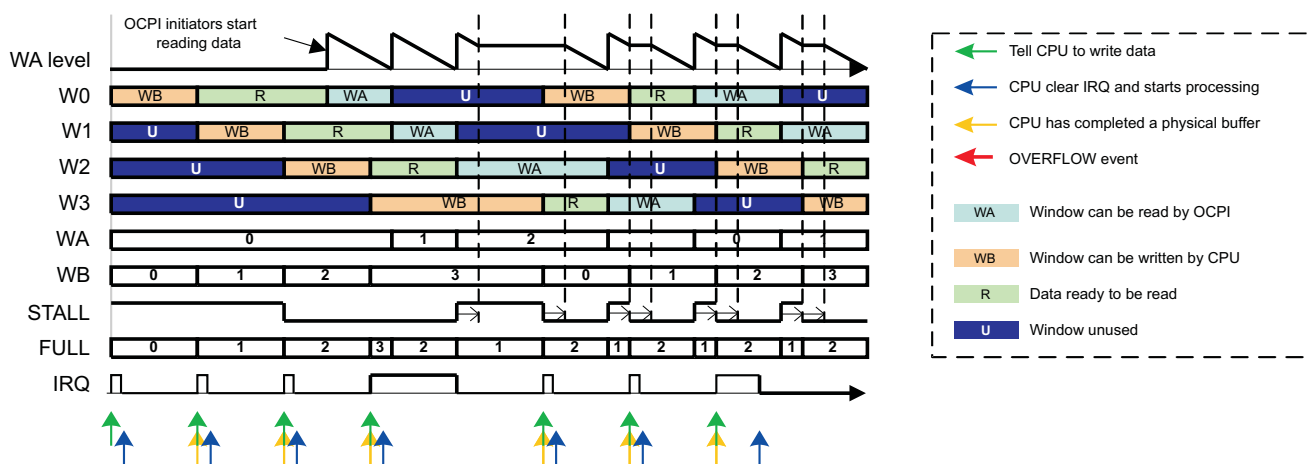

camss-307

Figure 8-94 is another example. It assumes:

- Read mode: The CPU writes data into physical space and the OCPI reads it.
- Four physical windows
- $CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i$
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- $CBUFF_CTX_CTRL_i[7:4] BCF = 2$

Figure 8-94. ISS CBUF Read Mode CPU Interaction Example (1)

camss-308

Figure 8-95 is another example. It assumes:

- Read mode: The CPU writes data into physical space and the OCPI reads it.
- Two physical windows
- $CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i$
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- $CBUFF_CTX_CTRL_i[7:4] BCF = 1$

Figure 8-95. ISS CBUFF Read Mode CPU Interaction Example (2)

Figure 8-96 is another example. It assumes:

- Read mode: The CPU writes data into physical space and the OCPI reads it.
- Four physical windows
- $CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i$
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- $CBUFF_CTX_CTRL_i[7:4] BCF = 1$

CBUFF supports pretriggering the BCF signal for finer latency compensation control. This mechanism is active only for the last window available for OCPI access. It typically improves the physical space use, which is particularly useful when on-chip SRAM is used as a ping-pong buffer.

Pretriggering is controlled through the $CBUFF_CTX_THRESHOLD_S_i$ register. It defines:

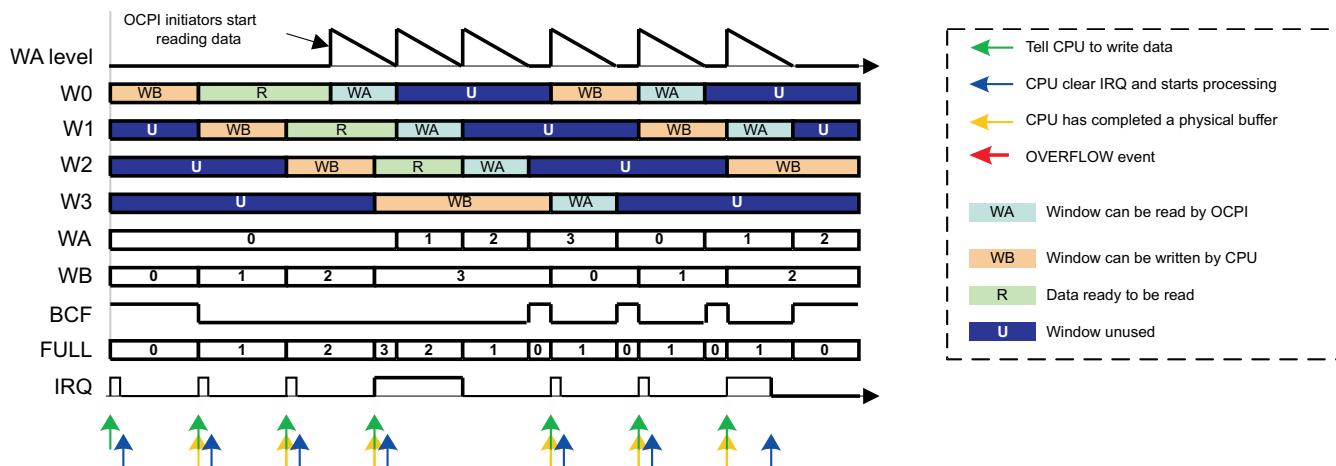

- Write mode: When the fill level of the last window available for ISS writes is greater than or equal to $CBUFF_CTX_THRESHOLD_S_i$, the $CBUFF_BCF$ signal is asserted.
- Read mode: When the amount of data in the last window available for ISS reads is less than $CBUFF_CTX_THRESHOLD_F_i / CBUFF_CTX_THRESHOLD_S_i$, the $CBUFF_BCF$ signal is asserted.

BCF pretriggering is disabled by setting $CBUFF_CTX_THRESHOLD_S_i = CBUFF_CTX_THRESHOLD_F_i$.

Figure 8-96 is an example of BCF pretriggering, assuming the following:

- Write mode: The CPU reads data from the physical space and the OCPI writes it.
- Two physical windows
- $CBUFF_CTX_THRESHOLD_S_i = 1/3 CBUFF_CTX_THRESHOLD_F_i$
- $CBUFF_CTX_CTRL_i[7:4] BCF = 1$

Figure 8-96. ISS CBUFF BCF Pretrigger Example: Write Mode

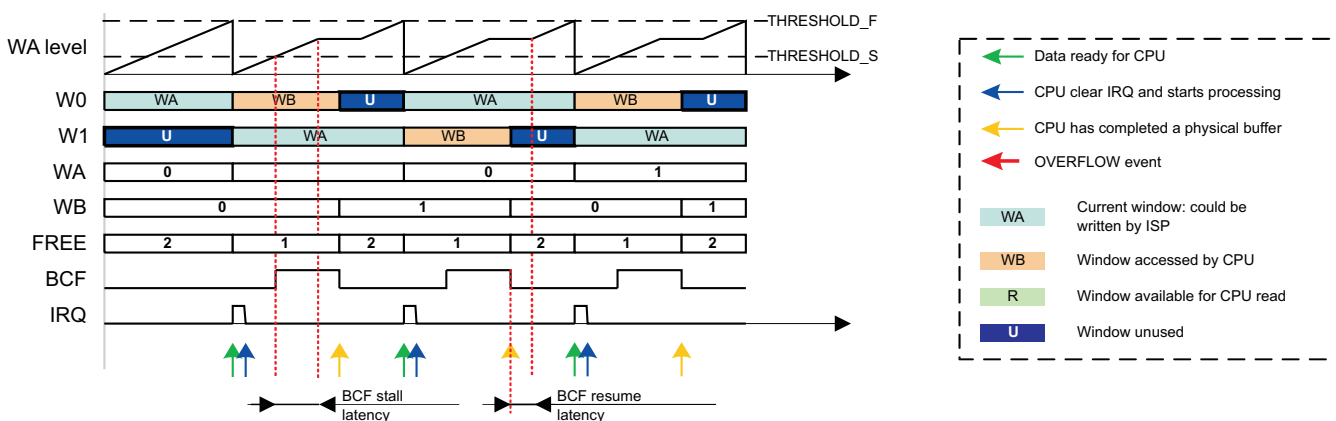

camss-310

The CBUFF_BCF output signal is a logical OR of all internal BCF signals of CBUFF contexts. For example, when contexts 0 and 1 have enabled the BCF feature, both contexts can request a data flow stall.

Figure 8-97 is an example of pretriggering in read mode:

- Read mode: CPU writes data into the physical space and the OCPI reads it.
- Four physical windows
- $CBUFF_CTX_THRESHOLD_S_i = 2/3 CBUFF_CTX_THRESHOLD_F_i$
- The OCPI read initiator is faster than the CPU. It starts after the CPU.
- $CBUFF_CTX_CTRL_i[7:4] BCF = 2$

Figure 8-97. ISS CBUFF BCF Pretrigger Example: Read Mode

camss-311

8.2.8.3.2.5 ISS CBUFF TILER Support

The CBUFF can translate 2D (BLOCK) bursts intended for the TILER. However, software must ensure that a given burst fits in a window.

The expected value for ADDR[32] is defined by the $CBUFF_CTX_CTRL_i[11]$ TILERMODE bit.

- When $ADDR[32] = CBUFF_CTX_CTRL_i[11]$ TILERMODE, the access is processed normally. ADDR[32] is not used for further processing.
- Otherwise, the access is treated as transparent.

8.2.8.3.2.6 ISS CBUFF Window Management and Address Remapping Details

This section explains the internal address remapping and windows management algorithm. Internally, the module maintains some variables in addition to the configuration registers. The module manages multiple contexts in parallel. [Table 8-266](#) lists the CBUFF internal variables.

Table 8-266. ISS CBUFF Internal Variables

| Variable | Description |
|----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WAx | Current window index for context x. Possible values are 0 to allowed window count. The current value can be read using the CBUFF_CTX_STATUS_i[11:8] WA bit field. |
| WBx | Window in the physical space that can be accessed by the CPU in read/write modes. Window that is read from OCPI in read/write mode. Possible values are 0 to allowed window count. The current value can be read using the CBUFF_CTX_STATUS_i[3:0] WB bit field. |
| VPAx | Start address, in the virtual space, of the CBUFF_CTX_STATUS_i[11:8] WA window |
| | Used as a base pointer for the read (read mode) or write data flow (write, read/write modes) |
| | This is an internal quantity that cannot be accessed by software. |
| VPBx | Start address, in the virtual space, of the CBUFF_CTX_STATUS_i[3:0] WB window |
| | Used as a base pointer for the read data flow. |
| | This is an internal quantity that cannot be accessed by software. |
| OFFSETAx | This is an internal quantity that cannot be accessed by software. |
| OFFSETBx | Address offset used when WAx or WBx is accessed |
| LEVELAx | This is an internal quantity that cannot be accessed by software. |
| LEVELBx | Address offset used when WAx or WBx is accessed |

8.2.8.3.2.6.1 ISS CBUFF Startup

The status of a CBUFF context is reset when it is disabled. This does not affect the configuration registers or the CBUFF_IRQSTATUS register. [Table 8-267](#) lists the internal state after reset.

Table 8-267. ISS CBUFF Internal State After Reset

| Variable | Description |
|----------------------|---------------------------------------------------------------------|
| WAx | 0 |
| WBx | 0 |
| VPAx VPBx | CBUFF_CTX_START_i |
| OFFSETAx OFFSETBx | CBUFF_CTX_START_i – CBUFF_CTX_PHY_i |
| LEVELAx LEVELBx | 0 |

8.2.8.3.2.6.2 ISS CBUFF Access Identification

For each access to the virtual space (OCPI slave port), the CBUFF first checks the address to classify the transaction into one of the categories listed in [Table 8-268](#).

Table 8-268. ISS CBUFF Address identification

| Address ID | Variable | Condition |
|------------|-----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0+2*x | WA_CBUFFx | CBUFF_CTX_CTRL_i[0] ENABLE = 1 and ADDR >= VP Ax and ADDR < VP Ax + CBUFF_CTX_WINDOWSIZE_i and ADDR <= CBUFF_CTX_END_i and Access type = write when read/write mode is selected |
| 1+2*x | WB_CBUFFx | CBUFF_CTX_CTRL_i[0] ENABLE = 1 and CBUFF_CTX_CTRL_i[2:1] MODE = 2 and |

Table 8-268. ISS CBUFF Address identification (continued)

| Address ID | Variable | Condition |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| | | Access type = read and ADDR >= VPBx and ADDR < VPBx + CBUFF_CTX_WINDOWSIZE _i and ADDR <= CBUFF_CTX_END _i |
| 16+x | ERR_CBUFFx | CBUFF_CTX_CTRL _i [0] ENABLE = 1 and ADDR >= CBUFF_CTX_START _i and ADDR <= CBUFF_CTX_END _i |
| 24 | TRANSPARENT | Always true |

Lower IDs correspond to higher priorities if multiple conditions are true. For example, when the current virtual window of CBUFF 0 is accessed, at least the tests for categories WA_CBUFFx and ERR_CBUFFx are true. The final category is WA_CBUFFx, because it has a higher priority.

NOTE: Tests must be performed in parallel to match the desired performance.

Further processing depends on the category:

- TRANSPARENT: Accesses flow through the module without changing its internal state or any translation.
- ERR_CBUFFx: The module goes into error state for the concerned context and sets the CBUFF_HL_IRQSTATUS.IRQ_CTXx_INVALID bit. When the module is in error state for CBUFFx, all accesses to that buffer are cancelled. In other words, any access that has an address between CBUFF_CTX_START_i and CBUFF_CTX_END_i is not transmitted to the OCPO master port. There are two ways to leave the error state:
 - Hardware reset
 - Disable and re-enable the context in error state.
 Accesses outside of the virtual space from the context in error state are not affected.
- WA_CBUFFx and WB_CBUFFx: The internal state is updated and address translation is performed when the performed access type (read or write) is compatible with the current mode (read, write, or read/write mode). Otherwise, a CBUFF_HL_IRQSTATUS.IRQ_CTXx_INVALID event is set and CBUFFx goes into the error state.

8.2.8.3.2.6.3 ISS CBUFF Address Translation

An offset is selected depending on the access category (see [Section 8.2.8.3.2.6.1, ISS CBUFF Startup](#)) and the internal state of the accessed buffer. [Table 8-269](#) lists possible cases.

Table 8-269. ISS CBUFF Address Translation

| Condition | Address Translation |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|
| CBUFF_CTX_CTRL _i [0] ENABLE = 1 and ADDR >= CBUFF_CTX_START _i and ADDR <= CBUFF_CTX_END _i and CBUFFx in error state | Access cancelled |
| Category = WA_CBUFFx | ADDRROUT = ADDRIN-OFFSETAx |
| Category = WB_CBUFFx | Read/write mode only ADDRROUT = ADDRIN-OFFSETBx |
| Category = ERR_CBUFFx | Access cancelled |
| Category = TRANSPARENT | ADDRROUT = ADDRIN |

8.2.8.3.2.6.4 ISS CBUFF Window Fill Level

Each time an access is performed into an active window (WA_CBUFF_x when context x is enabled) the window level is updated. The corresponding LEVEL_y is incremented according to the BYTEEN input of the OCPI slave port. All possible BYTEEN patterns, including nonaligned ones, are supported. [Table 8-270](#) shows some examples. The basic idea is to count the number of 1s in the BYTEEN input for each 128-bit word and to sum the values.

Table 8-270. ISS CBUFF Window-Level Increment

| BYTEEN | LEVEL _y Increment | Comment |
|--------|------------------------------|----------------|
| 0x0000 | 0 | No access |
| 0x0001 | 1 | 8-bit access |
| 0x0002 | 1 | 8-bit access |
| 0x0003 | 2 | 16-bit access |
| ... | ... | ... |
| 0x0007 | 3 | 24-bit access |
| ... | ... | ... |
| 0x000F | 4 | 32-bit access |
| ... | ... | ... |
| 0x00F0 | 4 | 32-bit access |
| ... | ... | ... |
| 0xFFFF | 16 | 128-bit access |

The window level is compared to CBUFF_x_THRESHOLD. [Table 8-271](#) lists the situations that may occur:

Table 8-271. ISS CBUFF Window-Level Comparison⁽¹⁾

| Condition | Description |
|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LEVEL _{Ax} >= CBUFF_CTX_THRESHOLD_F _i | The CBUFF_CTX_STATUS _i [11:8] WA bit field of context x is full (write mode) or empty (read mode). Internal window indexes, levels, and offsets are updated. |
| LEVEL _{Bx} >= CBUFF_CTX_THRESHOLD_F _i | Read/write mode only Window used to handle the read flow of context x is empty. Internal window indexes, levels, and offsets are updated. |

⁽¹⁾ All situations described in [Table 8-271](#) are mutually exclusive because only one level is updated each cycle.

8.2.8.3.2.6.5 ISS CBUFF Window Pointer and Offset Update

The following description refers to the update of WA in write mode:

When the current window of a context is full:

- A new window is opened. The update is done in a circular manner: the first physical window in is reused after the last one.
 - WA (WA + 1) modulo the number defined by CBUFF_CTX_CTRL_i[9:8] WCOUNT
 - LEVEL_A <- 0
 - VPA <- VPA + CBUFF_CTX_WINDOWSIZE_i
- When the window is moved from the last buffer to the first:
 - OFFSET_A <- OFFSET_A + CBUFF_CTX_WINDOWSIZE_i << (CBUFF_CTX_CTRL_i[9:8] WCOUNT + 1)
- Otherwise, OFFSET_A does not change.

The algorithm used to update WA in read mode is the same, except that *full* refers to *all data of the window has been read or window empty*.

For read/write mode, the same algorithm is used to translate reads to the WBx window. Make the following changes:

- Replace WA with WB.
- Replace LEVELA with LEVELB.
- Replace VPA with VPB.
- Replace OFFSETA with OFFSETB.

8.2.8.3.2.7 ISS CBUFF Error State

Contexts may go into error state when they receive unexpected accesses. In that case, the CBUFF does not send dummy transactions to the OCPO port. It does not forward the failing transactions to OCPO and returns valid responses (SResp = DVA) on OCPI to preserve the integrity of the OCP.

Responses may be received on OCPO while the CBUFF responds to failing transactions on OCPI. The OCPO response phase is stalled (MRespAccept = 0) during that time to prevent corruption. OCPO cannot be stalled longer than one full OCP transaction. Responses received on OCPO are handled before another internally generated response can be sent back to the OCPI. In that case, command and data phases are eventually stalled. Not stalling OCPO for too long is required to avoid affecting system performance.

During normal operation (that is, no context is in error state), the OCPO response phase is never stalled.

8.2.8.3.2.8 ISS CBUFF Typical Configurations

8.2.8.3.2.8.1 ISS CBUFF Single-Slice Buffer

An OCP master (typically, the ISS) writes data with an incremental addressing scheme to the virtual space. The physical space is smaller than the virtual space. Therefore, physical space locations are read and written multiple times. [Figure 8-98](#) shows the CBUFF single-slice buffer in write mode.

Figure 8-98. ISS CBUFF Single-Slice Buffer (Write Mode)

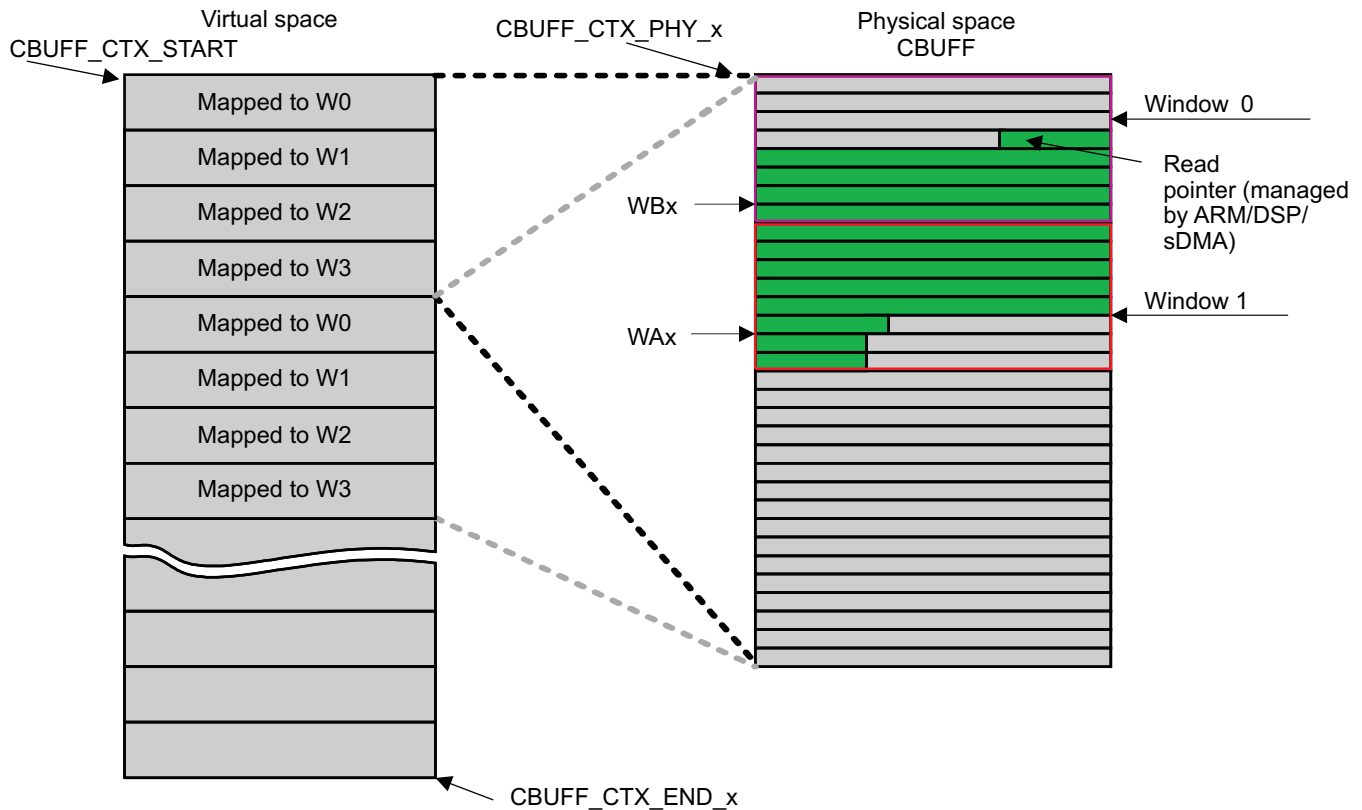

camss-313

Physically, this CBUFF is in on-chip SRAM or SDRAM. The virtual space is defined by a start and end addresses. The physical space is defined by a start address, a window size, and a window count. It is contiguous in memory. When the CPU accesses physical memory for processing, it must know if the SDRAM is available for it to access and if the CBUFF is not using it. The CPU and CBUFF cannot track each other. For example, an interrupt must be triggered from the SIMCOP to the CBUFF to notify it when the processor is done working with SDRAM. For more information about the software configuration for these interrupts, see [Section 8.2.8.3.2.2.1, ISS CBUFF Write Mode](#).

Figure 8-99 shows the buffer organization for a 4-window buffer.

Figure 8-99. ISS CBUFF Single-Slice Buffer Example (Write Mode)

camss-314

The CBUFF can manage multiple contexts in single-slice mode.

8.2.8.3.2.8.2 ISS CBUFF Extended-Slice Buffer

In extended-slice mode, at least two contexts managed by the CBUFF are used together. The two contexts provide address translation, one for the read data flow and the other for a write data flow. Figure 8-100 is an example of the CBUFF extended-slice buffer.

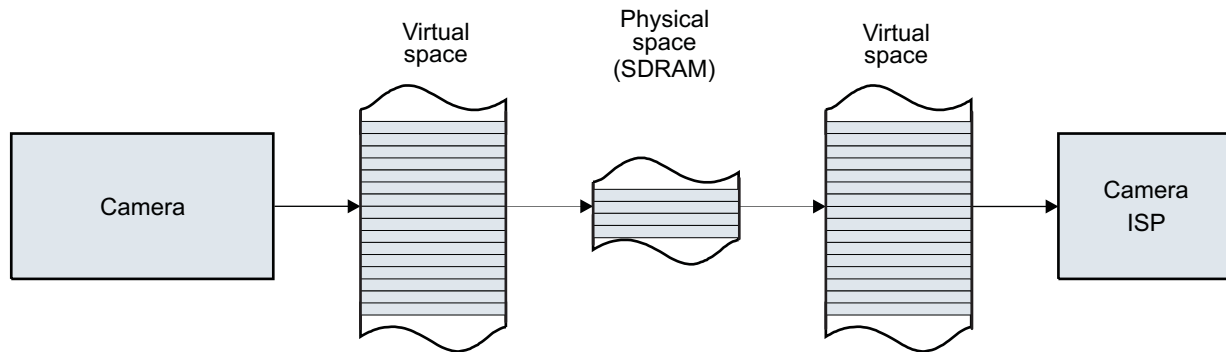

Figure 8-100. ISS CBUFF Extended-Slice Buffer Example

camss-315

8.2.8.3.2.9 ISS CBUFF FIFO Mode

The CBUFF can behave like a FIFO to buffer data between two initiators connected to the OCPI. A typical use case is a camera interface writing data to the FIFO and an ISP reading data from the FIFO. Figure 8-101 shows the CBUFF FIFO mode.

Figure 8-101. ISS CBUFF FIFO Mode

camss-316

The CBUFF is used as a FIFO when the camera provides data at a higher rate than the ISP can process. To avoid storing one or multiple full-frame buffers, a FIFO buffer is used to store the data that cannot be processed immediately.

For this example, assume that the camera provides 16 MPix at 15 frames per second. A new frame is provided every 66 ms. The ISP needs 80 ms to process this frame. Therefore, the processing cannot be done on the fly, and each other frame must be dropped.

Figure 8-102 shows the accumulated amount of data provided by the camera since the start of the frame; the amount of data consumed by the ISP since it has started processing the frame; and the difference between the two, which must be stored in the FIFO.

Figure 8-102. ISS CBUFF FIFO Use Example

camss-317

The FIFO is emulated as 16 windows (`CBUFF_CTX_CTRL_i[9:8] WCOUNT = 0x3`). The ISP is started by software when a few kilobytes of data are written to the physical space. Alternatively, the BCF mechanism can be used, but the minimum FIFO size is more complex to calculate.

The FIFO level reaches its maximum when the camera performs the last write of the frame. The camera provides the data at 1 byte/pixel 16 MPix/60 ms = 266 MBytes/s. The ISP reads data at 1 byte/pixel × 16 MPix/80 ms = 200 MBytes/s. Therefore, the minimum FIFO size is 60 ms × (266 MBytes/s – 200 MBytes/s) = 3.96 MBytes/s, which is four times less than a full-frame buffer.

Each window holds 256KB of data. The camera starts writing to a new physical window every 256KB/266 MBytes/s = 962 μs. The ISP starts reading from a new physical window every 1280 μs.

The FIFO mode can also be used when the ISP is slower than the camera. In that case, the ISP is stalled when insufficient data is available in the physical space.

8.2.8.4 ISS CBUFF Programming Model

8.2.8.4.1 ISS CBUFF Reset Behavior

Upon hardware or software reset of the CBUFF, all registers in the CBUFF are reset to their reset values

This software reset has the same effect as a hardware reset. ISS high-level software reset ensures that traffic is stopped on clear boundary because the CBUFF is sending data to and from other modules. ISS top-level reset is preferred. For more information about ISS software reset, see [Section 8.1.2.3, ISS Reset](#). Submodule reset is not preferred but is available through the following registers:

1. Set the [CBUFF_HL_SYSCONFIG\[0\] SOFTRESET](#) bit to 1.
2. Read the [CBUFF_HL_SYSCONFIG\[0\] SOFTRESET](#) bit to check whether it is set to 1, which means the reset occurred.

The reset is performed without waiting until all OCP traffic stops. To avoid OCP corruption, software must ensure there is no more ongoing traffic before performing a reset.

8.2.8.4.2 ISS CBUFF Register Setup

All registers of the context to be used must be initialized for correct operation. [Table 8-272](#) lists the procedure for the CBUFF register setup.

Table 8-272. ISS CBUFF Setup Register

| Step | Bit Field | Value |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|----------------------------------------------------------------------------|
| Set operation mode. | CBUFF_CTX_CTRL_i[2:1] MODE | 0x0: Write mode 0x1: Read mode 0x2: Read/write mode 0x3: Reserved |
| Define the virtual address range managed by the CBUFF. It usually corresponds to the address region where one image frame is written by the OCPI initiator. | CBUFF_CTX_START_i and CBUFF_CTX_END_i | |
| Define the start address of the physical buffer. | CBUFF_CTX_PHY_i | |
| Set the window count and size. The window size usually depends on the use of the buffer. Eight or 16 video lines correspond to a current size for JPEG video compression. A higher window count provides better latency-related overflow protection. | CBUFF_CTX_CTRL_i[9:8] WCOUNT and CBUFF_CTX_WINDOWSIZE_i | |
| When the 2D addressing capability is not used, set to the window size in CBUFF_CTX_THRESHOLD_F_i . Otherwise, it is set to a smaller value depending on the buffer organization. For example, when each window corresponds to lines by 4096 pixels, but the ISP sends lines of only 2560 pixels, CBUFF_CTX_WINDOWSIZE_i = 8 4096 and CBUFF_CTX_THRESHOLD_F_i = 8 2560. | CBUFF_CTX_THRESHOLD_F_i | |
| BCF signal-generation configuration is optional. | CBUFF_CTX_THRESHOLD_S_i and CBUFF_CTX_CTRL_i[7:4] BCF | |
| Enable the module. It can be disabled by clearing the ENABLE bit. This must be done only when there are no more outstanding requests to the virtual space managed by CBUFFx. All internal FSMs and counters of the CBUFF are reset when it is disabled. Pending interrupts are not affected. | CBUFF_CTX_CTRL_i[0] ENABLE | |

| RESERVED | | | | | | | | | | | TILERMODE | DONE | WCOUNT | BCF | | | RESERVED | MODE | ENABLE | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------|
| 31:12 | RESERVED | | R | 0x00000 |
| 11 | TILERMODE | Sets the expected value for ADDR[32]. If ADDR[32]=TILERMODE, ADDR[31:4] is processed and eventually translated. Otherwise, the access is handled as transparent, regardless of the other address bits. | RW | 0 |
| 10 | DONE | Write this bit to 1 to indicate the CPU has finished processing its physical buffer. This bit is automatically cleared by hardware, reads always return 0. This bit has no effect when MODE=2 (read/write) Write 0x0: No effect. Write 0x1: The CPU has completely processed the WB physical buffer. | W | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 9:8 | WCOUNT | Window count 0x0: 2 windows 0x1: 4 windows 0x3: 16 windows 0x2: 8 windows | RW | 0x0 |
| 7:4 | BCF | This register controls the bandwidth control feedback loop output. 0: Control loop disabled. 1-15: The control feedback loop enabled. Behavior depends on functional mode, see Section 8.2.8.3.2.4, ISS CBUFF Memory-to-Memory Operation BCF . | RW | 0x0 |
| 3 | RESERVED | | R | 0 |
| 2:1 | MODE | Selects the functional mode of this context 0x0: Write mode. ISS writes and CPU reads the physical space. CPU accesses are out of the scope of the CBUFF module; therefore, only writes are permitted between CBUFF_CTX_START__x and CBUFF_CTX_END__x. 0x1: Read mode. Hardware reads and CPU writes the physical space. CPU accesses are out of the scope of the CBUFF module; therefore, only reads are permitted between CBUFF_CTX_START__x and CBUFF_CTX_END__x. 0x2: Read/Write mode. Read and writes are monitored by the CBUFF. WB is used to track current read positions WA is used to track current write position. | RW | 0x0 |
| 0 | ENABLE | Enable/disable 0x0: Disables the context. This resets the internal state of the context. All accesses received on OCPI are transmitted to OCPO without modification. Disabling the context takes effect immediately. Software must ensure that no more accesses to the context are outstanding before disabling it. Otherwise memory corruption may occur. 0x1: Enable the context. All accesses between CBUFF_CTX_START__x and CBUFF_CTX_END__x are processed by the CBUFF. | RW | 0 |

8.3 ISS ISP

This section describes the image signal processor.

8.3.1 ISS ISP Overview

The image signal processor (ISP) is part of the image subsystem (ISS) of the device and is a key component for imaging and video applications. It describes all ISP modules in the multimedia device, that is, the video port (VP), pattern generator (PG), image pipe interface (IPIPEIF), image pipe module (IPIPE), resizer (RSZ), hardware 3A (H3A), image sensor interface (ISIF), and buffer logic (BL). For better understanding, see the first top-level ISS diagram and feature list in [Section 8.1, ISS Overview](#).

8.3.1.1 ISS ISP Features

The video-processing hardware removes the need for expensive camera modules to perform processing functions. The ISS can support the following features:

- On-the-fly or memory-to-memory processing
- Up to 200-MHz pixel throughput.
- Statistic data collection:
 - On-the-fly or memory-to-memory operation
 - Data collection for auto exposure
 - Data collection for auto white balance
 - Data collection for auto focus
 - Boundary signal calculation for video stabilization
- IPIPE front end: RAW data processing:
 - On-the-fly or memory-to-memory processing
 - 16-bit-wide RAW BAYER data path between image and sensor linearization module
 - 12-bit-wide RAW BAYER data path between sensor linearization module and gamma correction module. Gamma correction module outputs 10-bit data.
 - Programmable Bayer RGB positions
 - Sensor data linearization for dynamic range extension
 - Programmable 2D lens shading compensation (LSC) correction
 - Per-pixel gain and offset control
 - Black level compensation
 - Boxcar filter
 - Data collection for histogram generation
 - Defect pixel correction (LUT_DPC) with look-up table (LUT)
 - Defect pixel correction (OTF_DPC) with on-the-fly detection and correction
 - 2D noise filtering
 - Green imbalance correction (GIC)
 - Digital gains and offset
 - 8- to 10-bit A-law decompression and 10- to 8-bit A-law compression.
- IPIPE back end: RGB and YUV data processing:
 - RGB-to-RGB color correction
 - Gamma correction (GC).
 - RGB -> YUV4:2:2: Color conversion, cosited chroma filtering and downsampling
 - 2D edge enhancement (EE)
 - 3D LUT for color correction
 - False chroma suppression (FCS)
- Two resizers:

- Performance: input and output rates up to 200 MPix/s
- YUV4:2:2 to RGB56, ARGB888, YUV4:2:2 and YUV4:2:0 data output
- YUV4:2:0 to YUV4:2:0 data output
- RAW to RAW data output
- Range from x1/4096 to x20. Supports memory to memory rescaling.

The ISP comprises the following modules:

- Pattern generator (PG)
- IPIPE interface (IPIPEIF)
- Image sensor interface (ISIF) accelerator
- Auto exposure, auto white balance, and auto focus engine (H3A)
- Image pipe accelerator (IPIPE)
- Two resizer (RSZ) accelerators
- Buffer logic (BL): Receives module requests, performs arbitration, and creates read/write bursts to the memory subsystem

8.3.1.2 ISS ISP Block Diagram

[Figure 8-103](#) is the ISP top-level block diagram. The ISS supports three simultaneous pixel flows (CCP2, CSI2 A, and CSI2 B), but only one of them can use the video-processing hardware at a time; the others can go directly to memory.

The ISP master port is connected to the level 3 (L3) interconnect, and the slave port is connected to the level 4 (L4) interconnect.

[Figure 8-103](#) is the ISP block diagram.

Figure 8-103. ISS ISP Block Diagram

camss-003

8.3.2 ISS ISP Integration

This section describes the integration of the ISP modules in the ISS and includes information about clocks, resets, and hardware requests.

The ISP is part of the ISS of the device and is a key component for imaging and video applications such as camera viewfinder, video record, and still image capture.

ISS is coupled with a low interrupt latency ISS microprocessor unit (MPU) subsystem running a real-time operating system to reach optimal performance. Primarily, the ISS MPU subsystem can quickly change the ISS configuration during frame blanking periods and run some sequencing tasks.

8.3.2.1 ISS ISP PRCM Interface

The ISP and its internal modules, as integrated in the ISS, use the same power and clock management details. See [Section 8.1.2, ISS Functional Description](#), for the ISP top-level power, reset, and clock management (PRCM) Interface.

8.3.2.1.1 ISS ISP Clocks

The PRCM module, through the local power and clock management inside the ISS, provides a unique PCLK that can be enabled from the [ISP5_CTRL](#) register.

The modules inside the ISP require three clocks:

- PCLK: This clock is asynchronous to the other clocks. It is provided by the module sending the data to the IPIPEIF module on the VP.
- ISS_FCLK: This clock is synchronous with the configuration clock domain. This is the clock used for the MTC interface.
- GCK_MMR: This is the clock for the configuration bus. It is created from the ISS_FCLK and runs at half the speed of the ISS_FCLK.

8.3.2.1.2 ISS ISP Reset

The ISP supports global software reset along with internal hardware reset, if needed.

Software reset is done through the [ISP5_SYSCONFIG](#)[1] SOFTRESET bit. Before issuing a software reset, the ISP must be in standby mode. The following must be done:

- Ensure that the interfaces must be stopped from sending data and/or the ISP modules are disabled. Before reset, the last interrupt triggered by the ISP when the frame processing completes is RSZ_INT_DMA. RSZ_INT_DMA must be used to enable clean termination of the processing. Software must wait a few hundred cycles to trigger a soft reset after RSZ_INT_DMA is asserted; this is to ensure that the BL is completely drained.
- Ensure that [ISP5_SYSCONFIG](#)[5:4] STANDBYMODE = 2 (smart standby). Write the [ISP5_CTRL](#)[24] MSTANDBY bit to 1 and poll for [ISP5_CTRL](#)[20] MSTANDBY_WAIT = 1. Then, the soft reset can be applied ([ISP5_SYSCONFIG](#)[1] SOFTRESET = 1).

In case an ISP overflow event happens (for example, RSZ_FIFO_OVF, ISIF_OVF, etc.), it is not sufficient to reset the ISP. In that case a reset must take place at the ISS level.

8.3.2.2 ISS ISP Interrupt Tree

[Table 8-307](#) summarizes the submodule interrupts that can be mapped to the four ISP interrupt output lines. After this, these output lines are mapped to the ISS top interrupt request (IRQ) merger (for more information, see [Section 8.1.2](#)). Software enables the explained before merger from the top-level ISS resources registers in [Section 8.1.2](#).

Table 8-307. ISS ISP Interrupt Tree Table

| Register | Modules | Destination | Comments |

8.3.2.3 ISS ISP PG Integration

See [Section 8.3.2](#).

8.3.2.4 ISS ISP IPIPEIF Integration

8.3.2.4.1 ISS ISP IPIPEIF Interrupts

The IPIPEIF module generates two interrupts, one generic and one:

- IPIPEIF_IRQ: This event is triggered to the BL module when a new frame starts (VS signal). The interrupt is active low and is asserted for one GCK_MMR clock cycle.
- IPIPEIF_UDF: Interrupt generated when an underflow happens in the IPIPEIF module. Underflow events are nonrecoverable at the ISP level and a soft reset is required at the ISS level.

The interrupts are enabled from the [ISP5_IRQENABLE_SET_i](#)[9] IPIPEIF_IRQ and [ISP5_IRQENABLE_SET2_i](#)[1] IPIPEIF_UDF bits (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2, ISP Top-Level Integration](#).

8.3.2.5 ISS ISP IPIPE Integration

8.3.2.5.1 ISS ISP IPIPE Interrupts

IPIPE can generate several interrupts:

- IPIPE_INT_DPC_RNEW: This event is triggered when there is permission to initialize LUT-DPC table lines 0 and 1.
- IPIPE_INT_DPC_INI: This event is triggered when the DPC table is initialized.
- IPIPE_INT_HST: This event is triggered when the histogram is done.
- IPIPE_INT_BSC: This event is triggered when boundary signal calculation is done.
- IPIPE_INT_DMA: This event is triggered when the boxcar SDRAM transfer is done. On this timing, IPIPE_INT_EOF is sent to the BL. This event is active high for one GCK_MMR clock cycle.
- IPIPE_INT_LAST_PIX: This event is triggered when the last pixel of a frame comes into IPIPE. This event is active high for one GCK_MMR clock cycle.
- IPIPE_INT_EOF: This event is triggered for end of frame.
- IPIPE_BOXCAR_OVF: This event is generated when an overflow happens in the IPIPE-BOXCAR output buffer. The interrupt avoids polling the [IPIPE_SRC_STA](#)[0] VAL0 bit for errors. Overflow events are nonrecoverable at the ISP level and a soft reset is required at the ISS level.
- IPIPE_HST_ERR: This event is triggered when the MPU or system direct memory access (sDMA) is still reading the memory that is being used by the module. This is an indication that the read operation was not fast enough.

The interrupts are enabled from the [ISP5_IRQENABLE_SET_i](#) and [ISP5_IRQENABLE_SET2_i](#) registers (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2, ISP Top-Level Integration](#).

8.3.2.5.2 ISS ISP DMA Requests

The ISP generally outputs four direct memory access (DMA) requests, which can be used to read or write memories inside the IPIPE module. These memories are:

- BSC memory: This memory must be read during a vertical blanking period. It is used by the video stabilization application.
- HIST memory: This memory must be read during a vertical blanking period. It is used by the 3A application. The HIST data is double-buffered from frame-to-frame. Software must select the memory that is to be used by setting the [IPIPE_HST_TBL](#)[0] SEL bit.
- GAMMA memory: This memory must be set during a vertical blanking period. The imaging application typically uses multiple gamma tables.
- DPC memory: This memory must be set during a frame acquisition. The memory is not big enough to store all faulty pixels for a given frame.

To generate the DMA requests, the following events must be used:

- The IPIPE_INT_BSC event is used to generate the DMA request for the BSC memory. It maps on DMA line 0, ISS_DMA0.
- The IPIPE_INT_HST event is used to generate the DMA request for the HIST memory. It maps on DMA line 1, ISS_DMA1. The HIST data is double-buffered from frame-to-frame. Software must select the memory that is to be used by setting the [IPIPE_HST_TBL](#)[0] SEL bit. When the DMA request is set, it is required to read 4KB from the ping buffer address (0x2000) or the pong buffer address (0x3000). Software must ensure that when one buffer is selected no other accesses (for example, MPU) take place in the other buffer.
- The IPIPE_INT_LAST_PIX event is used to generate the DMA request for the GAMMA memory. This

same event can also be used to initialize the DPC LUT (not the preferred method; it is better to use IPIPE_INT_DPC_INI). Basically, when the last pixel is output from the IPIPE module, it is safe to modify the IPIPE memories. It maps on DMA line 3, ISS_DMA3.

- The IPIPE_INT_DPC_INI event signals that DPC table memory initialization can take place. IPIPE_INT_DPC_INI is used to generate two back-to-back DMA requests, the first one mapping on IPIPE_INT_DPC_RNEW0 and the second one mapping on IPIPE_INT_DPC_RNEW1. After initialization (steady state), the IPIPE_INT_DPC_RNEW0 and IPIPE_INT_DPC_RNEW1 events are used to generate the DMA request for the DPC LUT renewal. It maps on DMA line 2, ISS_DMA2. To select which event is used to initialize the DPC (IPIPE_INT_LAST_PIX or IPIPE_INT_DPC_INI), set the [ISP5_CTRL\[25\] DPC_EVT_INI](#) bit.

NOTE: The size of the DPC table in SDRAM must be exactly a multiple of the number of DMA requests. It ensures that during burst capture mode the DMA always load the correct data from frame-to-frame. The DMA automatically warps back to the start of the table after all expected DMA requests are received. There is a total of $\text{ceil}(\text{nb_faulty_pixel}/128) + 2$ DMA requests per frame when the IPIPE_INT_DPC_INI EVENT is used. Hence, the size of the DPC table in the SDRAM is $(\text{ceil}(\text{nb_faulty_pixel}/128) + 2) \times 128 \times 32$ bits.

NOTE: If DMA channels are not used but the MPU is used, an error check must be performed for IPIPE HST . See [ISP5_CTRL\[26\] HST_RD_CHK](#) for details.

The DMA request assertion and deassertion to the sDMA is automatic and no software intervention is needed. The ISP contains two registers ([ISP5_DMAENABLE_SET](#) and [ISP5_DMAENABLE_CLR](#)) that must be used to enable or disable generation of the DMA requests.

The DMA request deassertion is based on late deassertion; that is, the DMA request is disabled only when all the data corresponding to the transfer size have been read or written. To deassert the DMA request and generate the hw_eoi signal, hardware counts the number of 32-bit accesses that are done in the memory range of the corresponding DMA request through the ISP slave port. When the number of accesses corresponding to the DMA request is done, the DMA request is cleared. Multiple DMA requests can be active simultaneously.

Software must not attempt to read or write in the memory range of the DMA requests that are enabled because CPU accesses, instead of sDMA accesses, will be counted. Software can freely access ISP memories for which the DMA request is disabled, and can access registers while the sDMA performs the transfers.

8.3.2.6 ISS ISP RSZ Integration

8.3.2.6.1 ISS ISP RSZ PRCM Interface

8.3.2.6.1.1 ISS ISP RSZ Reset

The resizer module has no standalone software reset. RSZ must be reset at the ISP level. See [Section 8.3.2.1.2, ISS ISP Reset](#).

8.3.2.6.2 ISS ISP RSZ Interrupts

RSZ can generate several interrupts:

- **RSZ_INT_EOF0:** This event is triggered for end of frame.
- **RSZ_INT_EOF1:** This event is triggered for end of frame.
- **RSZ_FIFO_IN_BLK_ERR:** This event is triggered when the minimum vertical blanking period has not been respected, thus causing errors in the input data buffering submodule. This event is triggered when the RSZ_INT_REG event of frame N is triggered before RSZ_INT_DMA of frame N + 1. This event typically happens at the transition between two frames because there is not enough vertical blanking between frames. Hardware cannot recover from this error. It requires a reset. It is a requirement that despite the error, the RSZ module finishes correctly: ongoing requests are completed

and further requests are blocked.

- **RSZ_FIFO_OVF**: This event typically occurs while processing a frame, because the VP pixel clock is too high. Because hardware cannot recover from this error, a reset is required. It is a requirement that despite the error, the RSZ module finishes correctly: ongoing requests are completed and further requests are blocked.

This event signifies overflow in the following scenarios:

- In Bypass or Operating (normal/downscale) modes, the **RSZ_FIFO_OVF** event is triggered when overflow occurs in the input circular data buffer. The **rsz_stall_input** signal can be asserted by programming appropriate thresholds to prevent input FIFO overflow.
- In Pass-through mode, the **RSZ_FIFO_OVF** event is triggered when overflow occurs in the output MTC buffer. There is no hardware mechanism to prevent overflow in Pass-through mode.
- **RSZ_INT_CYC_RZA/RSZ_INT_CYC_RZB**: This event is triggered as circular interrupt every time that **RSZ_IRQ_RZA / RSZ_IRQ_RZB** output lines are written out to the **RZA_SDR_Y/RZB_SDR_Y** buffer. The range can go from 1 to 8192 lines. Usually, this value must be such that the circular buffer vertical size (set by the **RZBA_SDR_Y_PTR_E / RZBB_SDR_Y_PTR_E** register) is a multiple of **RSZ_IRQ_RZA/ RSZ_IRQ_RZA**.
- **RSZ_INT_DMA**: This event is triggered when the last EOF (of the two MTC interfaces) is sent out to the BL and the RSZ core has returned to idle. This event is active high for one GCK_MMR clock cycle.
- **RSZ_INT_LAST_PIX**: This event is triggered when the last pixel of the valid area is received. This event is active high for one GCK_MMR clock cycle.
- **RSZ_INT_REG**: This event is triggered when the new value of the shadowed registers, if updated, take effect on the next **RSZ_INT_REG** event. Then again, shadowed registers can be updated for the next frame after the **RSZ_INT_REG** event is triggered. This event is active high for one GCK_MMR clock cycle.

The interrupts are enabled from the **ISP5_IRQENABLE_SET_i** register (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2, ISP Top-Level Integration](#).

8.3.2.7 ISS ISP H3A Integration

8.3.2.7.1 ISS ISP H3A Interrupts

H3A can generate the following interrupts:

- **H3A_INT**: This event is triggered at the end of the last window or last pixel, whichever completes last. This always triggers at the same time as **H3A_INT_EOF**.
- **H3A_INT_EOF**: This event is triggered and generated at the end of the last window. This event is active high for one GCK_MMR clock cycle.
- **H3A_OVF**: This interrupt is generated when an overflow happens in the H3A output buffer. The interrupt avoids polling the **H3A_PCR[21]** OVF register for errors. Overflow events are nonrecoverable at the ISP level and a soft reset is required at the ISS level. The event is active high for one GCK_MMR clock cycle.

The interrupts are enabled from **ISP5_IRQENABLE_SET_i** and **ISP5_IRQENABLE_SET2_i** (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from the ISP is sent to the ISS top level, where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2, ISP Top-Level Integration](#).

8.3.2.8 ISS ISP ISIF Integration

8.3.2.8.1 ISS ISP ISIF Interrupts

ISIF can generate several interrupts:

- **ISIF_INT_0**: This event is triggered when the VD0 interrupt on line 0 is configured. The VD0 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in **VDINT0**. See [Section 8.3.3.7.19.1](#) for more details.

- ISIF_INT_1: This event is triggered when the VD1 interrupt on line 1 is configured. The VD1 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in VDINT1. See [Section 8.3.3.7.19.1](#) for more details.
- ISIF_INT_2: This event is triggered when the VD2 interrupt on line 2 is configured. The VD2 interrupt can be configured based on the VD position. It is asserted after receiving the number of horizontal lines (horizontal pulse signals) set in VDINT2. See [Section 8.3.3.7.19.1](#) for more details.
- ISIF_INT_3: This event is triggered LSC interrupt is an interrupt issued by the 2D-LSC block. See [Section 8.3.3.7.10.1.5](#) for more details.
- ISIF_OVF: Interrupt generated when an overflow happens in the ISIF module. The interrupt avoids polling the [ISIF_MODESET\[11\]](#) OVF register for errors.

The interrupts are enabled from the [ISP5_IRQENABLE_SET_i](#) and [ISP5_IRQENABLE_SET2_i](#) registers (where $i = 0$ to 3 for the line that will be mapped to the four lines of the ISP). Then, each line from ISP is sent to the ISS top level where it is muxed with other ISS modules for a total output of six interrupt lines. See [Section 8.1.2](#), *ISP Top-Level integration*.

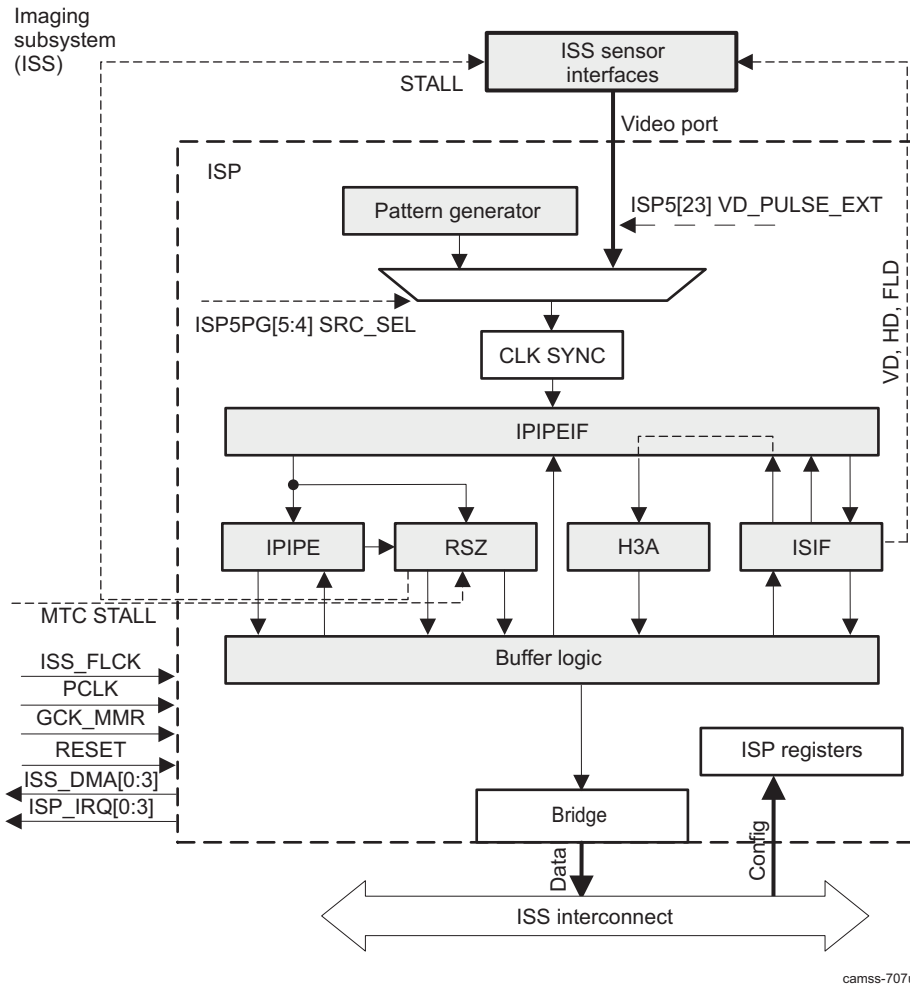

8.3.2.9 ISS ISP BL Integration

See [Section 8.3.2](#).

8.3.3 ISS ISP Functional Description

The functionality of the ISP is part of the overall performance of the ISS. For the top-level ISS diagram with ISP inside and for a features list, see [Section 8.1, ISS Overview](#). [Figure 8-104](#) is an overview of the ISP module. It outputs DMA and interrupt requests, has clocks coming in and a stall signal to the CCP2 interface receiver from the resizer. It also shows the top-level configuration for input to IPIPEIF. For the scaled-in functional details of each submodule inside the ISP, see its functional description section.

Figure 8-104. ISS ISP High-Level Diagram

camss-707u

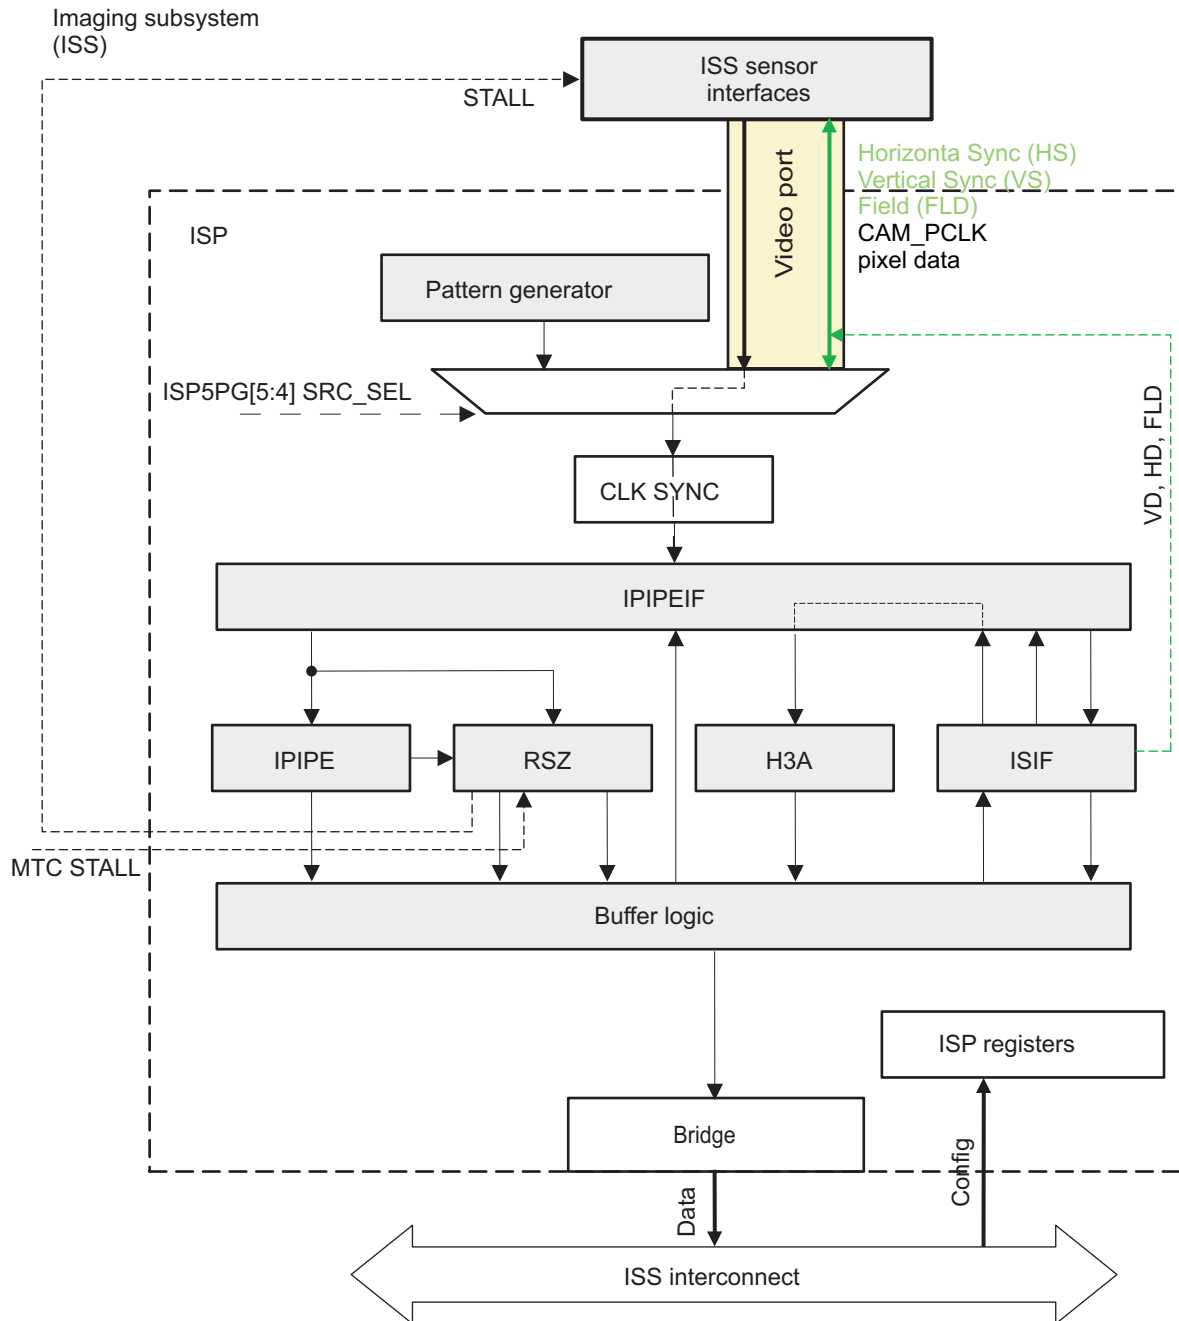

8.3.3.1 ISS ISP VP Functional Description

8.3.3.1.1 ISS ISP VP Overview

The VP supports a parallel interface that is used for interfacing with image sensors. The ISP VP can transport 8- to 16-bit RAW data and 8-/16-bit YCbCr data.

[Figure 8-105](#) lists the VP module connections to other submodules of the ISP.

Figure 8-105. ISS ISP VP High-Level Diagram

camss-699

8.3.3.1.2 ISS ISP VP Data Formats

The VP can be used to connect external camera receivers to the ISS. Data paths inside the ISP hardware depend on the image format sourced by the sensor (RAW RGB, YUV4:2:2, JPEG, etc.). [Table 8-308](#) shows how the CCP2/CSI2 modules are connected to the VP in function of the image format.

Table 8-308. ISS ISP VP Format Mapping

| Source | | Format | Connected to | | | | | | | | | | | | | | | ISIF GW DI | Data Provided to ISIF Linearization Engine | | | | | | | | | | | | | | | | | |

8.3.3.1.3 ISS ISP VP Top-Level Communication With CCP2 RX and CSI2 RX

At the ISS level, the VP is connected to the VP of the CCP2 RX and CSI2 RX modules. The interface that the VP uses to connect to the ISP is selected at the top-level of the ISS through the ISS_CTRL[3:2] INPUT_SEL bit. VP-implementation differences force the introduction of a bridge between the CCP2 RX/CIS2 RX modules and the VP. The role of the bridge is to perform VD pulse extension. The CCP2 RX module assumes that the VD signal is active for at least one pixel clock cycle, and the CSI2 RX module assumes that the VD signal is asserted for four pixel clock cycles. However, the ISP assumes that the VD pulse is active on at least one line.

Figure 8-106 shows how the VD pulse extension works. Assume that VD-IN is the VD signal at the input of the pulse extension bridge, and VD-OUT is the VD signal at the output of the pulse extension bridge.

The VD-OUT signal is asserted at the same time as VD-IN. The VD-OUT signal is kept high until one full line is received. A line is delimited by two rising edges of the HD signal. The VD-OUT pulse is deasserted on the next cycle after the falling edge of the HD signal.

Figure 8-106. ISS ISP VP VD Pulse

camss-691

The `ISP5_CTRL[23] VD_PULSE_EXT` bit controls whether the VD extension bridge is enabled or disabled. By default, the bridge is enabled. When the bridge is disabled, the VD pulse must be unmodified: $VD_OUT = VD_IN$. At the ISS level, it is expected that `ISP5_CTRL [23] VD_PULSE_EXT = 1` when the VP gets data from the CSI2 RX modules and `ISP5_CTRL[23] VD_PULSE_EXT = 0` when the VP gets data from the parallel interface or CCP2 RX module.

CAUTION

A minimum of four lines per frame are required on the VP when the VD pulse extension bridge is enabled; therefore, the VD extension bridge is not functional if a 1-/2-/3-line frame is sent to the VP.

8.3.3.1.4 ISS ISP VP Pixel Clock Inversion

The ISP always uses the rising edge of the pixel clock to sample the pixel data. The ISP provides the capability to invert the pixel clock so it can shift the resampling of a pixel clock period by half. This is controlled by the [ISP5_CTRL\[22\] PCLK_INV](#) bit. By default, the inversion is disabled. The 5 bits in [Table 8-309](#) are resynchronized from the GCK_MMR clock domain to the PCLK clock domain. There must be at least three clock cycles between the time these bits are modified and the HD/VD pulse for start of frame comes.

Table 8-309. ISS ISP VP GCK_MMR to PCLK Clock Resynchronization

| Module | Register | Bit Field |
|--------|------------------------------|-----------------|
| ISP | ISP5_CTRL | VD_PULSE_EXT |
| ISIF | ISIF_MODESET | HDVDD |
| ISIF | ISIF_MODESET | FIDD |
| ISP | ISP5_CTRL | ISIF_CLK_ENABLE |

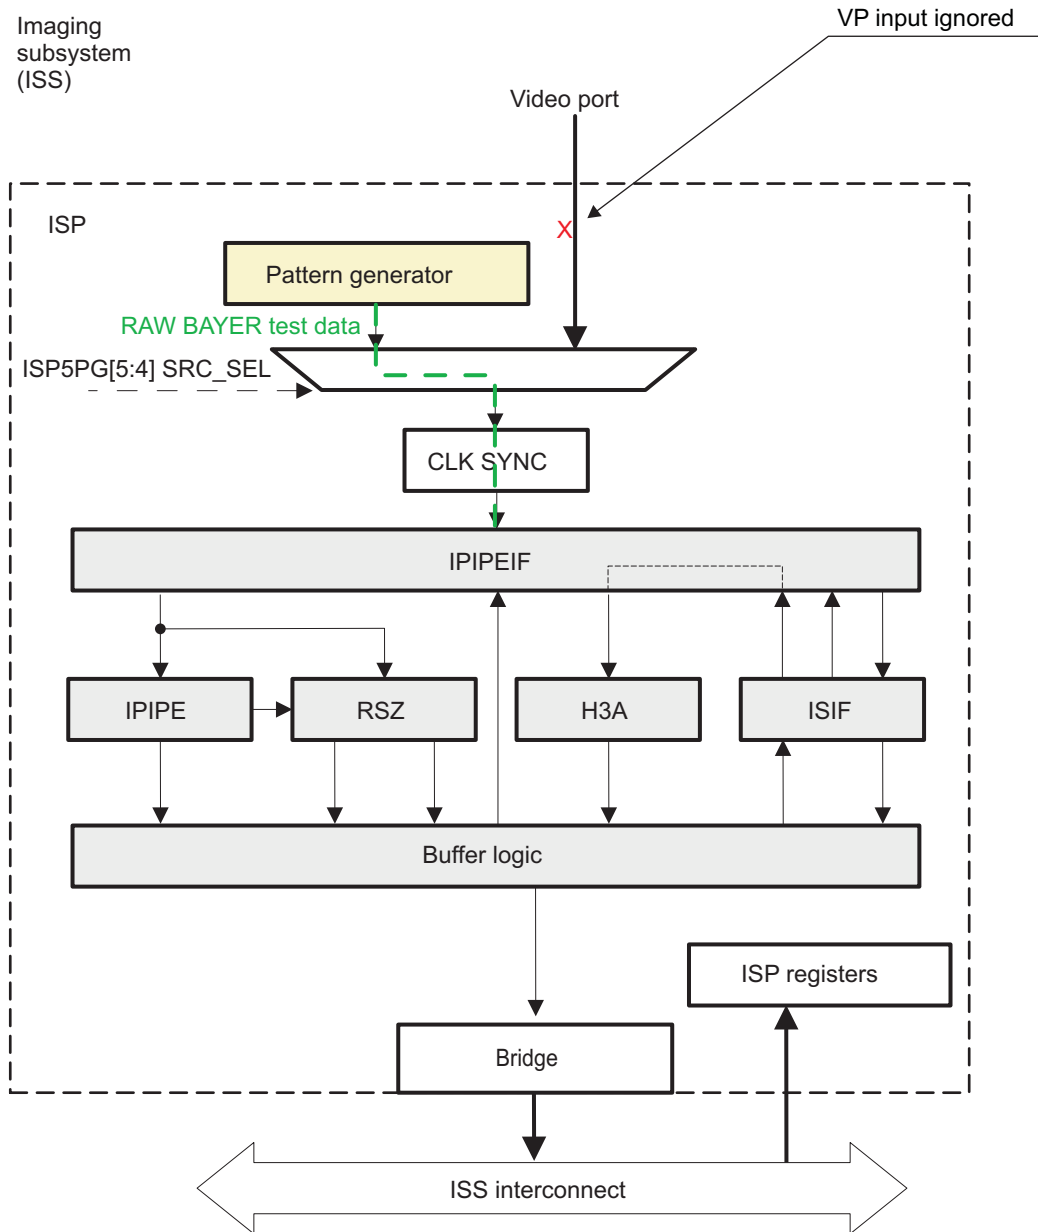

8.3.3.2 ISS ISP PG Functional Description

8.3.3.2.1 ISS ISP PG Overview

The pattern generator (PG) implements an internal data generation mechanism to test the external pins and can generate RAW data (to the IPIPEIF, ISIF, and other ISP modules) without the need for an external image sensor.

[Figure 8-107](#) show the PG module connections to other submodules of the ISP.

Figure 8-107. ISS ISP PG High-Level Diagram

camss-686

8.3.3.2.2 ISS ISP PG Functional Description

The data pattern is as follows:

- Data remain unchanged from frame to frame.
- Data are always generated as a BAYER pattern with RED (only on even/even pixel/line; other locations are RED = 0), GREEN (only on odd/even pixel/line and even/odd pixel/line; other locations are GREEN = 0) and BLUE (only on odd/odd pixel/line; other locations are BLUE = 0) colors.
- The frame is divided into four equal horizontal sections:
 - 1st horizontal section is further divided into eight equal vertical sections
 - 1st vertical section is RED only with maximum value (depending on number of bits programmed).
 - 2nd vertical section is RED and GREEN with maximum value.

- 3rd vertical section is RED, GREEN, and BLUE with maximum value.
- 4th vertical section RED and BLUE with maximum value.
- 5th vertical section is all zeros.
- 6th vertical section is GREEN and BLUE with maximum value.
- 7th vertical section is GREEN with maximum value.
- 8th vertical section is BLUE with maximum value.
- 2nd horizontal section is all RED with the pixel value linearly incrementing (reset to zero for each line) from zero onwards.
- 3rd horizontal section is all GREEN with the pixel value linearly incrementing (reset to zero for each line) from zero onwards.
- 4th horizontal section is all BLUE with the pixel value linearly incrementing (reset to zero for each line) from zero onwards.

By default, the ISP source is the VP. To select PG as the source for the ISP, set the [ISP5_PG\[5:4\] SRC_SEL](#) bit field to 0x3.

The [ISP5_PG\[2\] WEN](#) bit controls write-enable signal generation for the PG module. There are two modes: the write enable signal is enabled all the time or it is enabled and disabled every eight clock cycles. The [ISP5_PG\[1\] HDPOL](#) and [ISP5_PG\[0\] VDPOL](#) bits control the polarity of the horizontal and vertical synchronization signals generated by the PG module. These signals can be active high or active low.

The [ISP5_PG_PULSE_CTRL](#) register controls the HS and VS signal widths for the PG module.

- The [ISP5_PG_PULSE_CTRL\[12:0\] HDW](#) bit field sets the duration of the HD signal in terms of pixel clock cycles. The actual duration of the signal is [ISP5_PG_PULSE_CTRL\[12:0\] HDW](#) + 1 cycle. The minimum signal duration is one cycle, and the maximum signal duration is 4096 cycles.
- The [ISP5_PG_PULSE_CTRL\[27:16\] VDW](#) bit field sets the duration of the VD signal in terms of lines. The actual duration of the signal is [ISP5_PG_PULSE_CTRL\[27:16\] VDW](#) + 1 line. The minimum signal duration is one line, and the maximum signal duration is 4096 lines.

The [ISP5_PG_FRAME_SIZE](#) register controls the PG module horizontal and vertical frame sizes.

- The [ISP5_PG_FRAME_SIZE\[31:16\] PPLN](#) bit field sets the number of pixels per line a frame generated by the PG module. The actual number of pixels in a line is set by [ISP5_PG_FRAME_SIZE\[31:16\] PPLN](#) + 1. The minimum number of pixels is 1.
- [ISP5_PG_FRAME_SIZE\[15:0\] HLPFR](#) sets the number of lines per frame generated by the PG module. The actual number lines is set by [ISP5_PG_FRAME_SIZE\[15:0\] HLPFR](#) + 1. The minimum number of lines is one.

The [ISP5_PG\[3\] EN](#) bit enables or disables the PG module.

8.3.3.3 ISS ISP IPIPEIF Functional Description

8.3.3.3.1 ISS ISP IPIPEIF Overview

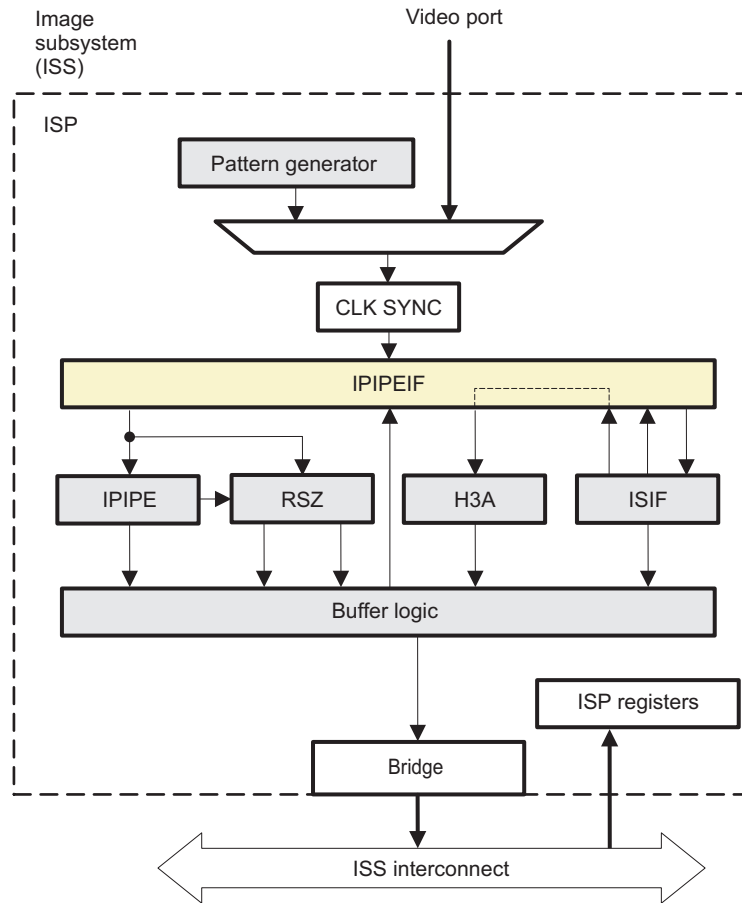

The IPIPEIF module provides data and synchronization signals (HD, VD) for the ISIF, IPIPE, RSZ, and H3A modules. The data source of this module is the VP, ISIF, or SDRAM using BL, and the selected data is output to ISIF, IPIPE, H3A, and RSZ. This module supports the following features:

- Supports up to 16 bpp data on the VP
- Supports up to 200-MHz pixel clock on the VP, up to 8K × 8K imaging resolution
- Supports RAW and YUV data formats on the VP and BL ports
- Supports dark-frame subtract of 8-bit RAW image stored in SDRAM from image from VP
- Supports dark-frame subtract of 8-bit RAW image stored in SDRAM from image from ISIF
- Supports dark-frame subtract of 8-bit RAW image from VP from image read from SDRAM through the BL
- Supports simple defect correction to prevent the subtraction of defect pixels
- Supports 8-10, 8-12 DPCM of 10-8, 12-8 DPCM compressed data in SDRAM

- Supports simple and advanced DPCM predictor
- Supports inverse A-Law decompression of RAW data 10-8 A-Law compressed from SDRAM
- Supports 8-bit, 12-bit unpacking of 8-bit,12-bit packed SDRAM data
- Supports gain multiply for output data to IPIPE module
- Supports horizontal Bayer rescaler in the data paths to the IPIPE and H3A modules: supports (1, 2, 1) averager filter and supports horizontal pixel decimation
- Supports data rate control when reading data from SDRAM: fraction clock divider.
- Supports (1, 2, 1) averager filter and supports horizontal pixel decimation in the data path to the IPIPE for YUV data.

Figure 8-108 show the IPIPEIF module connections to other submodules of the ISP.

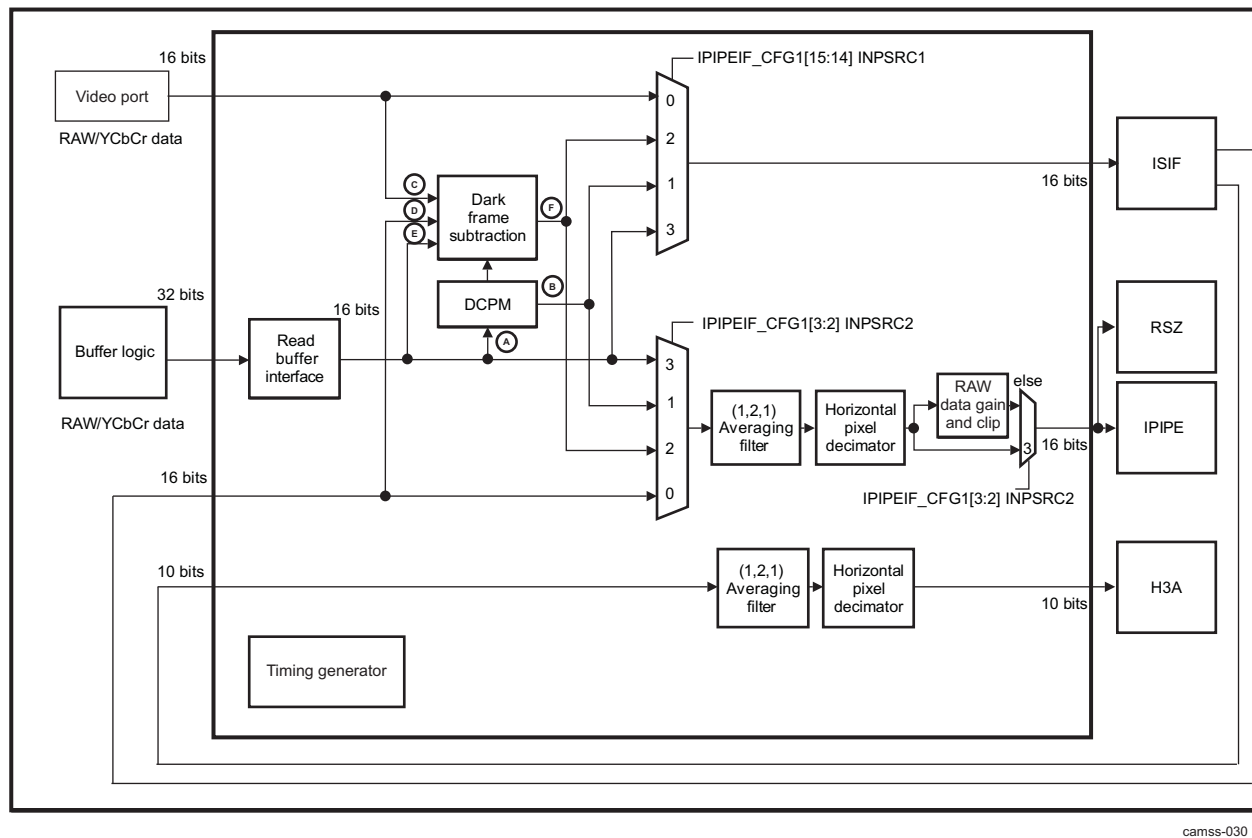

Figure 8-108. ISS ISP IPIPEIF High-Level Diagram

8.3.3.3.2 ISS ISP IPIPEIF Top-Level Block Diagram

The following sections describe the function of each subblock in the IPIPEIF, as shown in Figure 8-109.

Figure 8-109. ISS ISP IPIPEIF Top-Level Block Diagram

NOTE: When the IPIPEIF receives data from the VP, the timing generator must be configured for HD, VD, and WEN. For more information, see [Section 8.3.3.3.5, ISS ISP IPIPEIF Timing Generation](#).

8.3.3.3.3 ISS ISP IPIPEIF Input Interface

The IPIPEIF module comprises two major interface blocks: VP and BL. The data types can be RAW or YUV.

8.3.3.3.3.1 ISS ISP IPIPEIF Input From VP

The VP typically receives data from the image sensor. At the ISS level, it is connected to the serial interface receivers.

8.3.3.3.3.2 ISS ISP IPIPEIF Input From BL

The BL is the interface with the memory (SDRAM). In that case, the SDRAM address and line offset registers must be programmed in units of 32 bytes.

- SDRAM start address (byte) = $(\text{IPIPEIF_ADDRU}[10:0] \text{ ADDRU}) \ll 16 + (\text{IPIPEIF_ADDRL}[15:0] \text{ ADDR L})$
- SDRAM address offset (byte) = $\text{IPIPEIF_ADOFS}[11:0] \text{ ADOFS}$

Two types of data can be stored in memory: pixel data and dark frame data.

For pixel data, the HD and VD signals are reconstructed with:

- [IPIPEIF_HNUM](#)
- [IPIPEIF_VNUM](#)

- IPIPEIF_LPFR
- IPIPEIF_PPLN

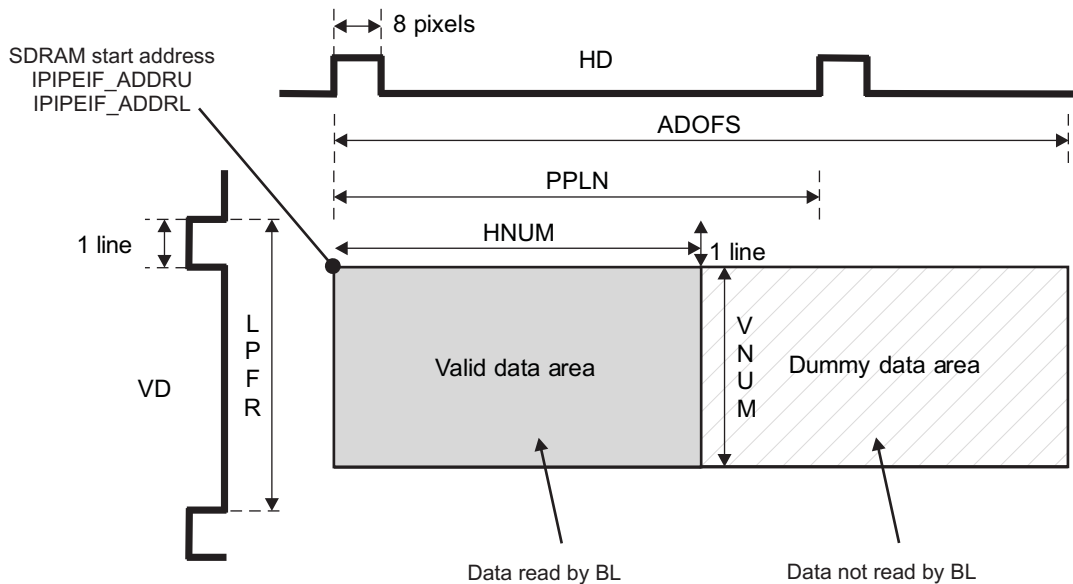

The IPIPEIF_HNUM and IPIPEIF_VNUM registers define the number of pixels per line and lines per frame to read from the SDRAM, and the IPIPEIF_LPFR and IPIPEIF_PPLN registers define the interval of VD and HD, respectively.

Vertical blanking for the frame is defined with the following equation: $IPIPEIF_LPFR - IPIPEIF_VNUM - 1$.

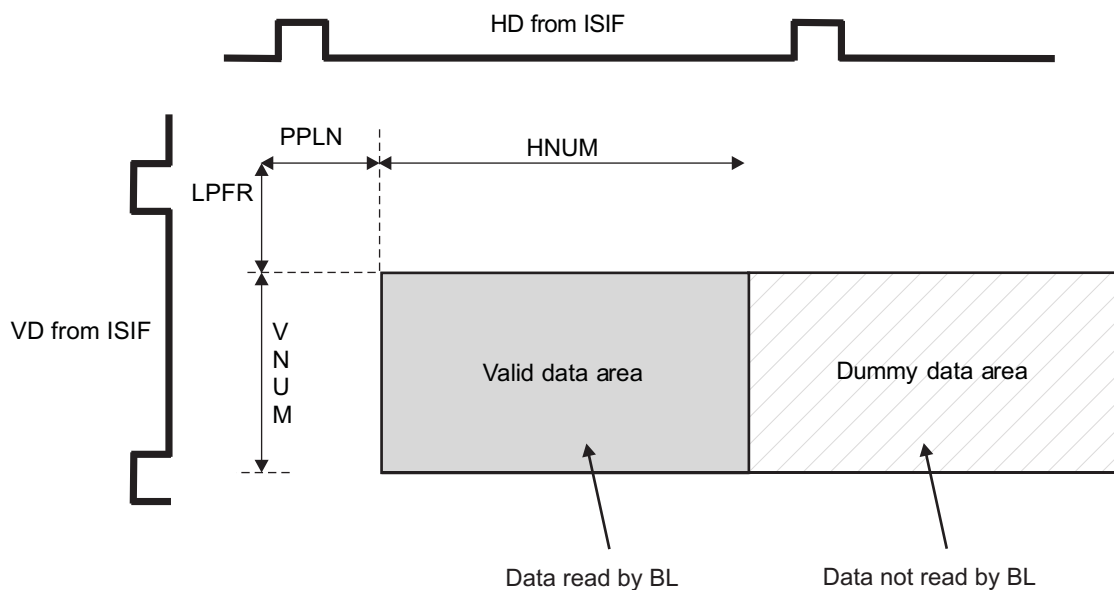

Horizontal blanking for the frame should be at least eight ISS_FCLK cycles, and is defined with the following equation: $IPIPEIF_PPLN - IPIPEIF_HNUM > 7$.

Figure 8-110 shows the global frame definition for all SDRAM input modes, except for dark frame subtract.

Figure 8-110. ISS ISP IPIPEIF Global Frame Definition in SDRAM Input Modes (Except Dark Frame)

For dark frame data, the HD and VD signals come from the VP through the ISIF. The IPIPEIF_PPLN and IPIPEIF_LPFR registers should be used to indicate the horizontal and vertical start position of the subtraction from the ISIF data, as shown in Figure 8-111. The value of the IPIPEIF_LPFR [12:0] LPFR bit field must be greater than 0 because the first line from the VP or ISIF cannot be subtracted from. The IPIPEIF_HNUM and IPIPEIF_VNUM registers must be used to set the number of valid pixels horizontally and the number of valid lines vertically.

Figure 8-111. ISS ISP IPIPEIF Global Frame Definition in Dark Frame Subtract Mode

camss-034

8.3.3.3.2.1 ISS ISP IPIPEIF Double-Buffer Input Function When Reading From BL

The IPIPEIF module supports a double-buffer input function. This feature is most useful when SDRAM space is limited, because it enables to read continuously from two buffers and to push data to the rest of the ISP (ISIF, H3A, etc.) for further processing.

Consider the following configuration where data are read from two buffers, A and B. The intent is not only to read continuously from these buffers but also to ensure that the ISP modules consider the data as being from the same frame; that is, VD is generated the first time buffer A is read, but it must not toggle until all the frames are read.

The IPIPEIF module can mask the VD sync signal by writing the `IPIPEIF_ENABLE[1] SYNCOFF` bit but such that the IPIPEIF module drives the data to the ISP modules as if it is a continuous frame data.

In the following example, there are 16 lines per trigger and input circular addressing. $VNUM = 16$ (see [Figure 8-110](#)), and the VD signal is generated only for the first frame (see [Figure 8-112](#)).

Figure 8-112. ISS ISP IPIPEIF Double-Buffer Functionality

camss-615

8.3.3.3.4 ISS ISP IPIPEIF Data Path Selection

The data path configuration through the IPIPEIF module is set with the IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 bit fields. Table 8-310 lists the possible combinations for these two bit fields.

Table 8-310. ISS ISP IPIPEIF IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 Possible Combinations

| IPIPEIF_CFG1[15:14] INPSRC1 | IPIPEIF_CFG1[3:2] INPSRC2 | Description | Common Use |
|-----------------------------|---------------------------|---------------------------------------------------------------------------------------------------|------------------------------------------------------------------------|
| 0 | 0 | This data path is described in Section 8.3.3.3.4.1, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 0 . | Video record, view finder, on-the-fly still image capture applications |
| 0 | 1 | This data path is described in Section 8.3.3.3.4.2, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 1 . | Memory to IPIPE to memory |
| 0 | 2 | This data path is described in Section 8.3.3.3.4.3, ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 2 . | Image capture with on-the-fly dark frame subtraction |

Table 8-310. ISS ISP IPIPEIF IPIPEIF_CFG1[15:14] INPSRC1 and IPIPEIF_CFG1[3:2] INPSRC2 Possible Combinations (continued)

| IPIPEIF_CFG1[15:14] INPSRC1 | IPIPEIF_CFG1[3:2] INPSRC2 | Description | Common Use |
|------------------------------------|----------------------------------|---------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | 3 | This data path is described in Section 8.3.3.3.4.4 , <i>ISS ISP IPIPEIF INPSRC1 = 0 and INPSRC2 = 3</i> . | On-the-fly data acquisition done in VP, forwarded to the ISIF, and then to the H3A through IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory YUV4:2:2 or RAW data processing with the IPIPE and RESIZER modules from memory to memory fetched by IPIPEIF |
| 1 | 0 | This data path is described in Section 8.3.3.3.4.5 , <i>ISS ISP IPIPEIF INPSRC1 = 1 and INPSRC2 = 0</i> . | Memory-to-ISIF- to memory operation |

| 2 | 0 | This data path is described in Section 8.3.3.3.4.6 , <i>ISS ISP IPIPEIF INPSRC1 = 2 and INPSRC2 = 0</i> . | Dark frame subtraction is performed and data sent to the ISIF module for further processing, back to IPIPEIF, and then to IPIPE and RSZ. |
| 2 | 1 | This data path is not supported. | N/A |
| 2 | 2 | This data path is not supported. | N/A |
| 2 | 3 | This data path is not supported. | N/A |
| 3 | 0 | This data path is described in Section 8.3.3.3.4.7 , <i>ISS ISP IPIPEIF INPSRC1 = 3 and INPSRC2 = 0</i> . | Memory-to-ISIF-to memory operation |
| 3 | 1 | This data path is not supported. | N/A |
| 3 | 2 | This data path is not supported. | N/A |
| 3 | 3 | This data path is possible but there is no use case associated. | N/A |

8.3.3.3.4.1 ISS ISP IPIPEIF INPSRC1= 0 and INPSRC2 = 0

Set the [IPIPEIF_CFG1\[15:14\] INPSRC1](#) bit field to 0 and the [IPIPEIF_CFG1\[3:2\] INPSRC2](#) bit field to 0.

This configuration can be used for the video record, viewfinder, and on-the-fly still image capture applications. The full ISP processing capability is used in a single pass.

[Figure 8-113](#) shows the data path.

Figure 8-113. ISS ISP IPIPEIF INPSRC1= 0 and INPSRC2 = 0 Data Path

camss-603

8.3.3.3.4.2 ISS ISP IPIPEIF INPSRC1= 0 and INPSRC2 = 1

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 0 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 1. This configuration can be used to process data with the IPIPE module from memory to memory. The data stored in SDRAM can be decompressed (A-law or DPCM) before being forwarded to the IPIPE module.

NOTE: In this configuration, the ISIF and H3A modules are assumed to be disabled.

Figure 8-114 shows the data path.

Figure 8-115. ISS ISP IPIPEIF INPSRC1= 0 and INPSRC2 = 2 Data Paths

camss-610

8.3.3.3.4.4 ISS ISP IPIPEIF INPSRC1= 0 and INPSRC2 = 3

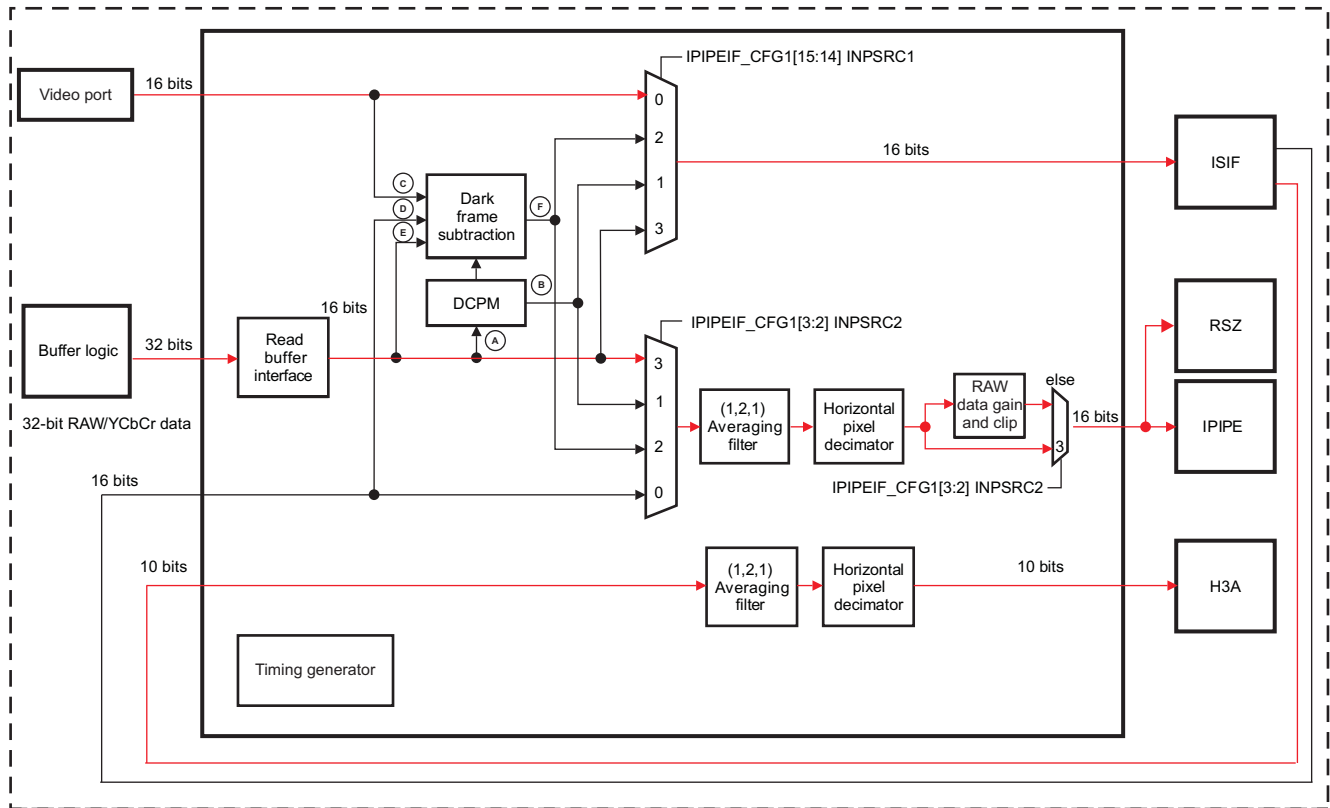

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 0 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 3.

In the first case, on-the-fly data acquisition is done with the VP, forwarded to the ISIF, and then sent to the H3A through the IPIPEIF while data from memory is processed and forwarded to the IPIPE module and then stored in memory.

In the second case, the configuration can be used to process YUV4:2:2 or RAW data with the IPIPE and RESIZER modules from memory to memory. The YUV4:2:2 or RAW data stored in the SDRAM is fetched and forwarded to the IPIPE and RSZ modules. ISIF and H3A are assumed to be disabled in this configuration.

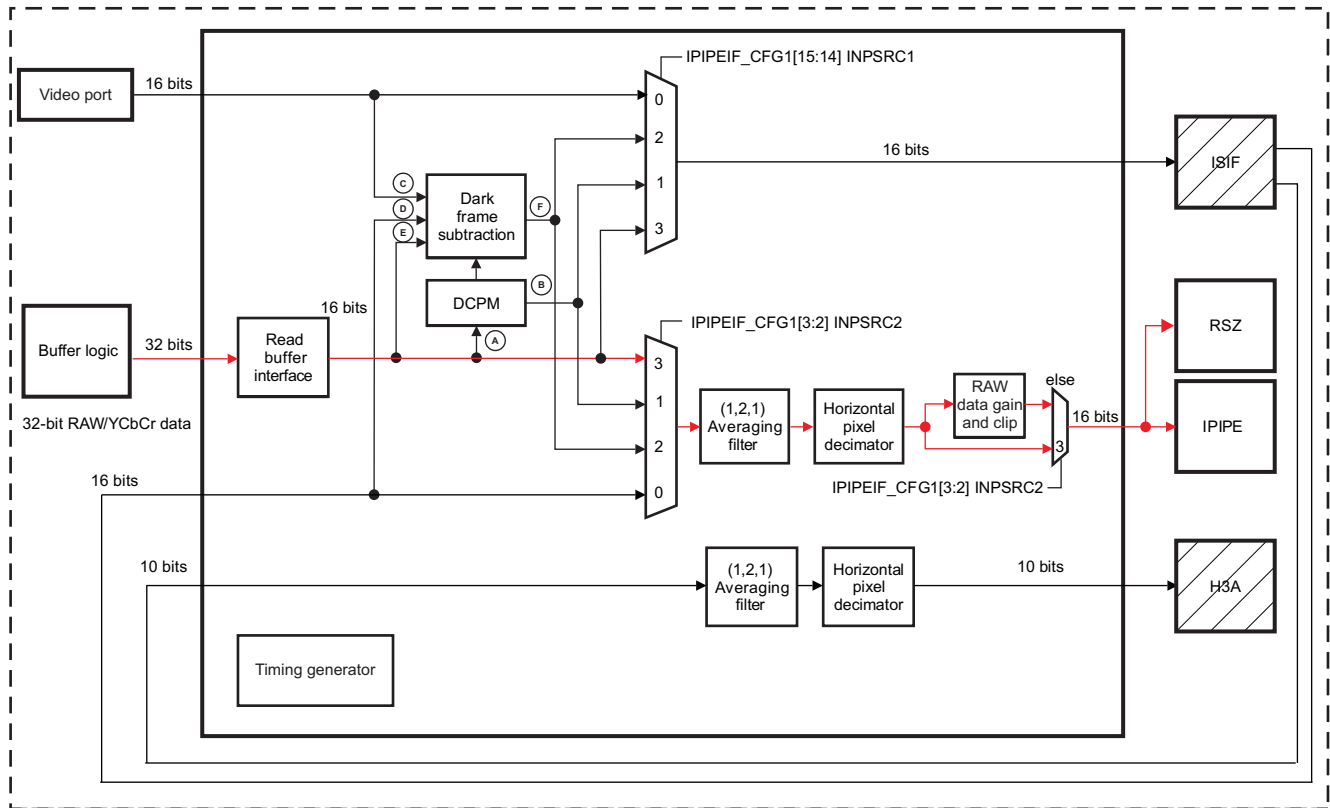

Figure 8-116 and Figure 8-117 show the two possible data paths.

Figure 8-116. ISS ISP IPIPEIF INPSRC1= 0 and INPSRC2 = 3 Data Paths: First Case

camss-606

Figure 8-117. ISS ISP IPIPEIF INPSRC1= 0 and INPSRC2 = 3 Data Paths: Second Case

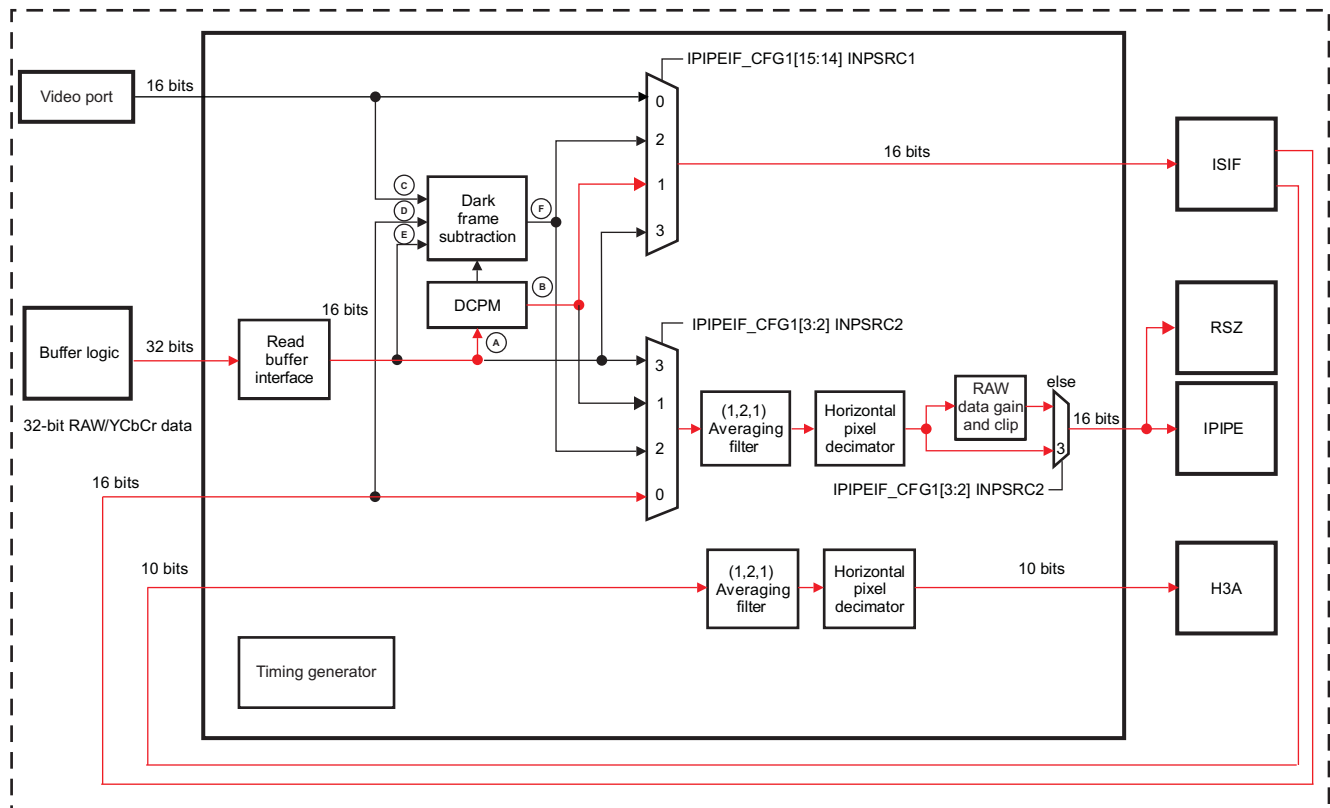

camss-605

8.3.3.3.4.5 ISS ISP IPIPEIF INPSRC1= 1 and INPSRC2 = 0

Set the IPIPEIF_CFG1[15:14] INPSRC1 bit field to 1 and the IPIPEIF_CFG1[3:2] INPSRC2 bit field to 0.

This configuration is a memory-to-memory operation. RAW data is read by the BL interface, decompressed, and pushed to the ISIF. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE and H3A modules.

Figure 8-118 shows the data path.

Figure 8-118. ISS ISP IPIPEIF INPSRC1= 1 and INPSRC2 = 0 Data Path

camss-607

8.3.3.3.4.6 ISS ISP IPIPEIF INPSRC1= 2 and INPSRC2 = 0

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 2 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 0.

In this configuration, dark frame subtraction is performed and data is sent to the ISIF module. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ modules. There are two possible dark frame subtractions: the first is with data coming from the VP and the dark frame coming from the BL; the second is with data coming from BL and the dark frame coming from the VP.

Figure 8-119 shows the data path.

Figure 8-119. ISS ISP IPIPEIF INPSRC1= 2 and INPSRC2 = 0 Data Path

camss-608

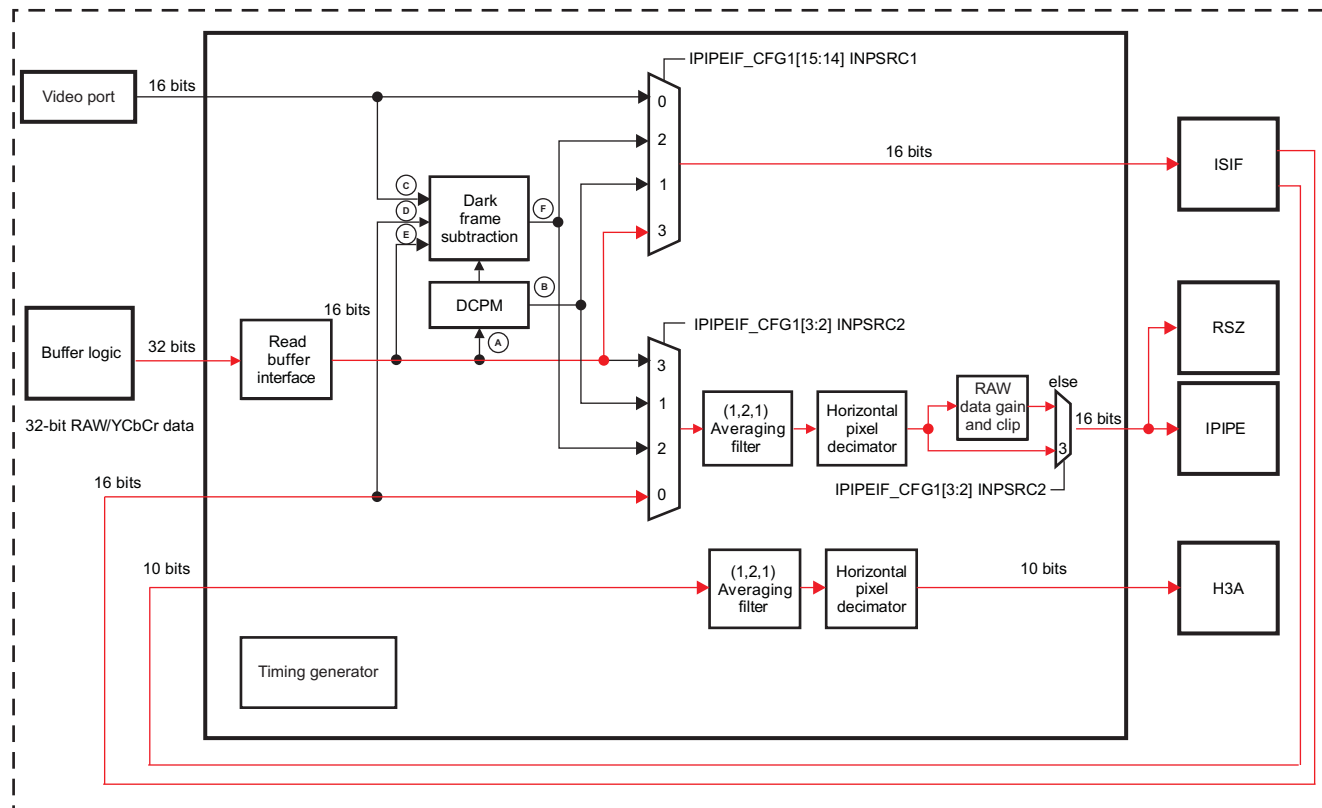

8.3.3.3.4.7 ISS ISP IPIPEIF INPSRC1= 3 and INPSRC2 = 0

Set the `IPIPEIF_CFG1[15:14] INPSRC1` bit field to 3 and the `IPIPEIF_CFG1[3:2] INPSRC2` bit field to 0.

This configuration is a memory-to-memory operation. Data is loaded from the SDRAM. Input data is expected as 16 bpp. The ISIF processes the data and sends it back to the IPIPEIF module before the data is pushed to the IPIPE or RSZ module.

In this configuration data is assumed to be YUV only, and H3A and RAW data gain are assumed to be disabled.

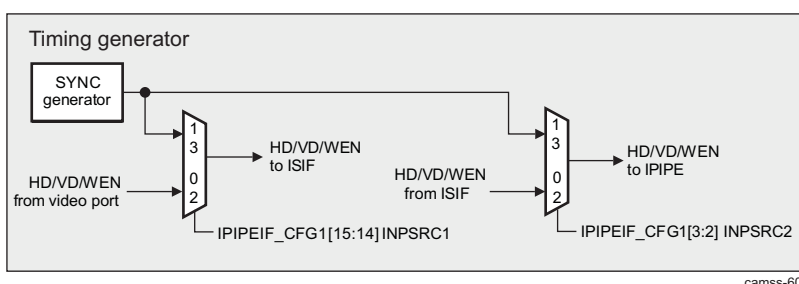

Figure 8-120 shows the data path.

Figure 8-120. ISS ISP IPIPEIF INPSRC1= 3 and INPSRC2 = 0 Data Path

camss-609

8.3.3.3.5 ISS ISP IPIPEIF Timing Generation

Figure 8-121 shows the ISS ISP IPIPEIF timing generator submodule.

Figure 8-121. ISS ISP IPIPEIF Timing Generator Submodule Description

camss-602

When the IPIPEIF module input source is from the VP (`IPIPEIF_CFG1[15:14] INPSRC1 = 0 or 2`) or the ISIF (`IPIPEIF_CFG1[3:2] INPSRC2 = 0 or 2`), the `IPIPEIF_CFG1[10] CLKSEL` bit must be set to 0 so that data is latched using the PCLK, HD, and VD signals from the VP.

When the IPIPEIF module input source is not from the VP (`IPIPEIF_CFG1[15:14] INPSRC1 = 1 or 3`), the `IPIPEIF_CFG1[10] CLKSEL` bit must be set to 1 so that the IPIPEIF module generates its proper PCLK, HD, and VD signals (through the use of the SYNC generator). The `IPIPEIF_CLKDIV` register is then used to select a divide ratio of the SDRAM (DMA) clock for the pixel clock frequency, which is used to clock the data into the PCLK. See [Section 8.3.3.3.5.1, ISS ISP IPIPEIF Fractional Clock Divider](#).

When the `IPIPEIF_CFG1[15:14] INPSRC1` or `IPIPEIF_CFG1[3:2] INPSRC2` bit field is not set to 0, the IPIPEIF SDRAM data reading and timing generation can be enabled (`IPIPEIF_ENABLE[0] ENABLE`) in one-shot mode or continuous mode (`IPIPEIF_CFG1[0] ONESHOT`).

8.3.3.3.5.1 ISS ISP IPIPEIF Fractional Clock Divider

When the input data of the IPIPEIF module does not come from the VP but from memory, it is useful to have control of the rate at which the data is fetched from memory to avoid overflow conditions or to avoid peak bandwidth requirements. The IPIPEIF_CFG1[10] CLKSEL bit is equal to 1 for fractional divider use.

The ISP clock ISS_FCLK is divided to generate the pixel clock, which goes to the ISIF and IPIPE modules when data is read from memory (IPIPEIF_CFG1[15:14] INPSRC1 = IPIPEIF_CFG1[3:2] INPSRC2 = 1 or 3). The IPIPEIF_CLKDIV register selects the divider ratio: M and N values in the IPIPEIF_CLKDIV[15:0] CLKDIV bit field.

Given an input clock of clock rate ISS_FCLK, the fractional clock divider generates an output clock with average clock rate f_out.

Where f_out = ISS_FCLK x M/N, and M = 1 through 256, and N = 1 through 256.

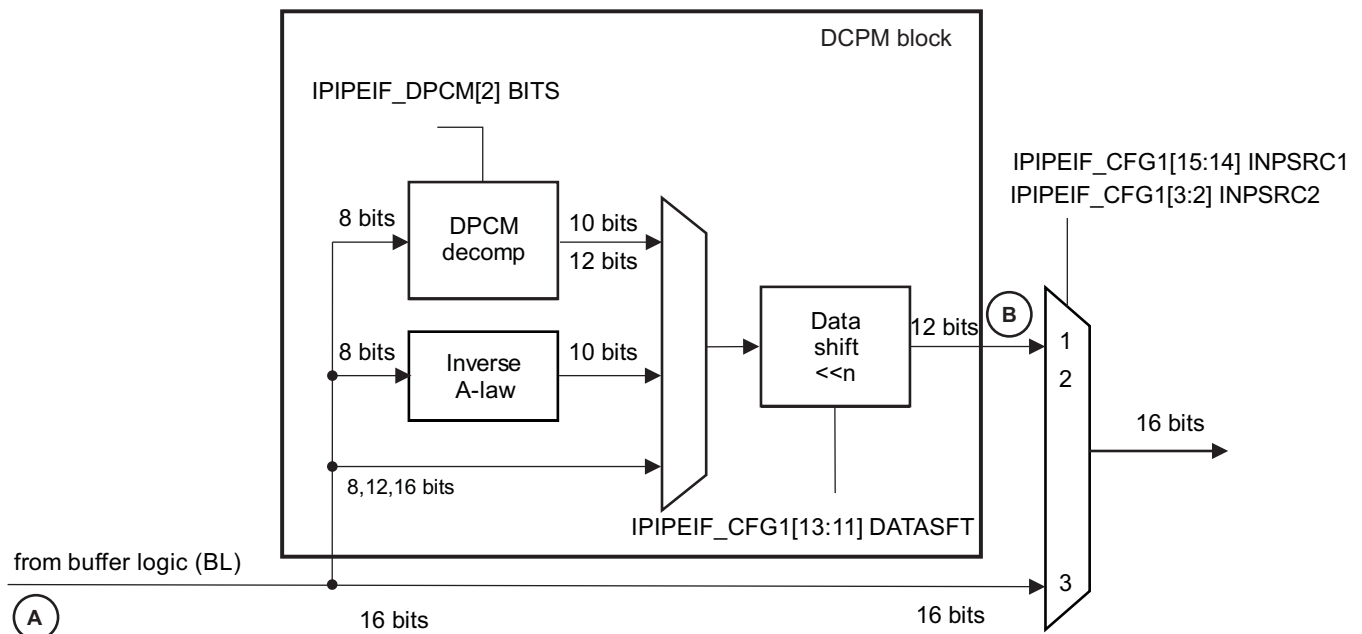

The fractional clock divider logic is synchronous and uses only the positive clock edge of the input clock.

8.3.3.3.6 ISS ISP IPIPEIF Decompression (DCPM) Subblock: Unpack and Decompression Function

The IPIPEIF module can read RAW data from memory. The RAW data can be previously packed/compressed into memory. Unpack, A-Law decompression, and DPCM decompression are available in the IPIPEIF module.

Figure 8-122 shows the DCPM subblock.

Figure 8-122. ISS ISP IPIPEIF DCPM Subblock

camss-032

Table 8-311 provides the possible configuration of the DCPM block.

Table 8-311. ISS ISP IPIPEIF DCPM Block Possible Configuration

| Number of Bits per Pixel at DCPM Block Input | Number of Bits per Pixel at DCPM Block Output | Description | Registers |
|----------------------------------------------|-----------------------------------------------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 16 | 16 | It can correspond to YUV4:2:2 or RAW16 data. | IPIPEIF_CFG1[9:8] UNPACK = 0x0 In this configuration, IPIPEIF_CFG1[3:2] INPSRC2 = 0x3. In this configuration data bypasses the DCPM block. |

Table 8-311. ISS ISP IPIPEIF DCPM Block Possible Configuration (continued)

| Number of Bits per Pixel at DCPM Block Input | Number of Bits per Pixel at DCPM Block Output | Description | Registers |
|----------------------------------------------|-----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8 | 8 | PACK8: YUV | IPIPEIF_CFG1 [9:8] UNPACK = 0x1 IPIPEIF_DPCM [0] ENA = 0x0 IPIPEIF_CFG1 [13:11] DATASFT = 0x01. In this configuration an 8-bit packed RAW data is used in DFS mode or YUV4:2:0 pass through. (See section 1.3.3.13) |
| 8 | 10 | DPCM10: The 8-bit input data are DPCM-decompressed in 10 bits. | IPIPEIF_CFG1 [9:8] UNPACK = 0x1 IPIPEIF_DPCM [0] ENA = 0x1 IPIPEIF_DPCM [2] BITS= 0x0 Set the IPIPEIF_DPCM [1] PRED ⁽¹⁾ ⁽²⁾ IPIPEIF_CFG1 [13:11] DATASFT = 0x2 |
| 8 | 12 | DPCM12: The 8-bit input data are DPCM-decompressed in 12 bits. | IPIPEIF_CFG1 [9:8] UNPACK = 0x1 IPIPEIF_DPCM [0] ENA = 0x1 IPIPEIF_DPCM [2] = 0x1 Set the IPIPEIF_DPCM [1] PRED ⁽¹⁾ ⁽²⁾ IPIPEIF_CFG1 [13:11] DATASFT = 0x0 |
| 8 | 10 | ALAW10: The 8-bit input data were previously A-law compressed. The 8 bits are A-law decompressed and padded with 0. | IPIPEIF_CFG1 [9:8] UNPACK = 0x2 IPIPEIF_CFG1 [13:11] DATASFT = 0x2 |
| 12 | 12 | PACK12: The input is coded on 12 bits and is packed in the SDRAM. This mode is compatible with the ISIF module packing capability. If inverse A-law and DPCM decomposition are not enabled, the data read from the SDRAM can be shifted by the IPIPEIF_CFG1 [13:11] DATASFT bit field to select which 12-bits to use. MSB input data bit must be shifted such that it corresponds to bit 11 after the shift. | IPIPEIF_CFG1 [9:8] UNPACK = 0x3 Set the IPIPEIF_CFG1 [13:11] DATASFT |

⁽¹⁾ The simple predictor uses only the value of the previous same color component as a prediction value. Therefore, only 2-pixel memory is required. It is typically used for 10–8–10 or 12–8–12 bit conversions.

⁽²⁾ The advanced predictor uses four previous pixel values, when the prediction value is evaluated. This means that the values of the other color components are also used, when the prediction value is defined. Therefore, the advanced predictor is slightly better than the simple predictor but consumes more power and memory. It can, however, improve image quality. It is typically used for 10–7–10 and 10–6–10 bit conversions.

8.3.3.3.7 ISS ISP IPIPEIF Dark-Frame Subtraction Functionality

Figure 8-123. ISS ISP IPIPEIF Dark-Frame Subtraction Subblock

camss-033

The dark-frame subtract function is used to remove noise from the sensor. Typically, the ISIF module previously writes a dark frame (frame captured when the shutter is closed) to SDRAM using 8-bits of linear data packed into 2 pixels per 16 bits.

In this mode, RAW data from the ISIF and SDRAM is used. Data can also be read from SDRAM with the [IPIPEIF_CFG1\[9:8\] UNPACK](#) bit field set to 1. Each pixel read from SDRAM is subtracted from each pixel sent from the VP or ISIF.

The mux at the input of the dark-frame subtraction subblock is implicitly controlled by the selection of the [IPIPEIF_CFG1\[15:14\] INPSRC1](#) and [IPIPEIF_CFG1\[3:2\] INPSRC2](#) bit fields:

- When [IPIPEIF_CFG1\[15:14\] INPSRC1](#) = 0x2, the selected input ports are VP and BL. Therefore, the dark frame operation can be:
 - Dark frame = VP – BL
 - Dark frame = BL – VP
- When [IPIPEIF_CFG1\[3:2\] INPSRC2](#) = 0x2, the selected input ports are ISIF and BL. Therefore, the dark frame operation can be:
 - Dark frame = ISIF – BL
 - Dark frame = BL – ISIF

The output of the dark frame subtract operation is 12-bits wide (U12Q0). There must be adequate SDRAM bandwidth if this feature is enabled. If the data fetched from memory arrives late, there is an underflow bit ([IPIPEIF_DTUF](#)) that must be triggered to know it .

8.3.3.3.7.1 ISS ISP IPIPEIF Defect Pixel Correction

NOTE: For the defect pixel correction (DPC) memory access locations, see [Section 8.3.3.9](#).

A simple DPC can be applied to the ISIF or VP input data path and SDRAM input data path, respectively. This DPC algorithm is intended to correct hot pixels during RAW dark frame acquisition or dark frame readout from SDRAM before dark frame subtraction.

The following code describes DPC algorithm:

```

If (image(n) < TH) || ((image(-2) > TH)&& (image(n+2) > TH)
    image(n) = image(n)
Else if image(-2) > TH
    image(n) = image(n+2)
Else if image(n+2) > TH
    image(n) = image(-2)
Else
    image(n) = (image(-2)+ image(n+2))/2

// Where TH is equal to IPIPEIF_DPC1[11:0] TH for DPC1
// Where TH is equal to IPIPEIF_DPC2[11:0] TH for DPC2

```

The [IPIPEIF_DPC1\[12\]](#) ENA bit enables DPC for the VP/ISIF input path, and the [IPIPEIF_DPC2\[12\]](#) ENA bit enables DPC for the SDRAM input path. The algorithm requires a threshold value that is set by the [IPIPEIF_DPC1\[11:0\]](#) TH or [IPIPEIF_DPC2\[11:0\]](#) TH bit field that is a 12-bit unsigned value.

8.3.3.3.7.2 ISS ISP IPIPEIF DFS Subtraction Direction

The [IPIPEIF_CFG2\[5\]](#) DFSDIR bit selects how the DFS subtraction is performed.

- Set the [IPIPEIF_CFG2\[5\]](#) DFSDIR bit to 0 when the RAW data is coming from the VP/ISIF and the dark frame is stored in SDRAM.
- Set the [IPIPEIF_CFG2\[5\]](#) DFSDIR bit to 1 when the RAW data is coming from SDRAM and the dark frame is coming from the VP/ISIF.

After subtraction, a clip ensures that the value is not negative.

[Table 8-312](#) lists the different modes supported in DFS.

Table 8-312. ISS ISP IPIPEIF DFS Modes Supported

| Description | DFDIR Value |
|------------------------------------------------------------------------------------------|----------------------------------------------|
| Dark frame subtract of 8-bit RAW image stored in SDRAM from image from VP | IPIPEIF_CFG2[5] DFSDIR = 0x0 |
| Dark frame subtract of 8-bit RAW image stored in SDRAM from image from ISIF | IPIPEIF_CFG2[5] DFSDIR = 0x0 |
| Dark frame subtract of 8-bit RAW image from VP from image read from SDRAM through the BL | IPIPEIF_CFG2[5] DFSDIR = 0x1 |

NOTE: DFS input depends on the INPSRC1 and INPSRC2 settings.

8.3.3.3.8 ISS ISP IPIPEIF (1, 2, 1) Averaging Filter for IPIPE Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled ([IPIPEIF_CFG1\[1\]](#) DECIM), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can be enabled by setting the [IPIPEIF_CFG1\[7\]](#) AVGFILT bit. It operates on every other pixel (same color) in RAW Bayer input or every Y component in YCbCr data in the following equation:

$$\text{output} = (\text{input}[i - 1] + 2 \times \text{input}[i] + \text{input}[i + 1]) \gg 2$$

The averaging filter operates on every other pixel (same color) in RAW Bayer input or YUV data.

If the data is YUV4:2:2, the option to average and decimate is given under the conditions listed in [Table 8-313](#).

Table 8-313. ISS ISP IPIPEIF Averaging Filter Conditions for YUV4:2:2 Data

| IPIPEIF_CFG1[3:2] INPSRC2 | IPIPEIF_CFG2[3] YUV16 | Comments |
|----------------------------------|------------------------------|-------------------------------------------------------------------------------------------------------------------------|
| 0 | 1 | YUV4:2:2 data is coming from the ISIF module. Averager and decimation is possible on the data path to the IPIPE module. |
| 1 | 1 | YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module. |
| 3 | | YUV4:2:2 data is read from SDRAM. Averager and decimation is possible on the data path to the IPIPE module. |
| Other value | Other value | For YUV4:2:2 data, averager and decimation is not possible on the data path to the IPIPE module. |

The averager implements a (1, 2, 1) FIR filter on Luma and Chroma. The following registers have a part in the behavior of the YUV data averaging and decimation:

- [IPIPEIF_INIRSZ\[12:0\]](#) INIRSZ
- [IPIPEIF_CFG1\[7\]](#) AVGFILT
- [IPIPEIF_CFG1\[1\]](#) DECIM

8.3.3.3.9 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for IPIPE Data Path

The IPIPE input is limited to 5376 pixels per horizontal line due to line memory width restrictions in the IPIPE.

To process image sensor resolutions with more than 5376 pixels per line with no resolution loss, vertical frame division mode (FDM) must be used; that is, the image must be divided into vertical chunks of less than 5376 pixels, and each chunk must be processed by the ISP sequentially. FDM is memory-to-memory processing and is not supported on the fly.

Alternatively, if a loss in resolution is acceptable, the line width decimator (the [IPIPEIF_CFG1\[1\]](#) DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 5376 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the [IPIPEIF_RSZ\[6:0\]](#) RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled ([IPIPEIF_INIRSZ\[13\]](#) ALNSYNC = 0x1), the [IPIPEIF_INIRSZ\[12:0\]](#) INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator, as shown in [Figure 8-124](#).

Figure 8-124. ISS ISP IPIPEIF Resizer Offset Definition

8.3.3.3.10 ISS ISP IPIPEIF RAW Data Gain for IPIPE Data Path

A gain factor ranging from 0.00195(1/512) to 1.99805(1023/512) is multiplied to the RAW output of the IPIPEIF. The gain is not applied if the input data is YCbCr. The gain constant is set in the [IPIPEIF_GAIN\[9:0\]](#) GAIN bit field using U10Q9 format.

The output value is clipped after gain control through the value of the [IPIPEIF_OCLIP\[11:0\]](#) OCLIP bit field.

8.3.3.3.11 ISS ISP IPIPEIF (1, 2, 1) Averaging Filter for H3A Data Path

The averaging filter acts as an anti-aliasing low-pass filter for the horizontal pixel decimator. Usually, when horizontal pixel decimation is enabled (the [IPIPEIF_RSZ3A\[9\]](#) DECIM bit), the averaging filter must also be enabled to avoid aliasing artifacts. The averaging filter can also be used to reduce noise before H3A statistics generation. It operates on every other pixel (the same color) in a RAW Bayer input or every Y component in YCbCr data. The averaging filter can be enabled by setting the [IPIPEIF_RSZ3A\[8\]](#) AVGFILT bit, and it operates with the following equation:

$$\text{output} = (\text{input}[i - 1] + 2 \times \text{input}[i] + \text{input}[i + 1]) \gg 2$$

8.3.3.3.12 ISS ISP IPIPEIF Horizontal Pixel Decimator (Downsizer) for H3A Data Path

The H3A input is limited to 3008 pixels per horizontal line due to line memory width restrictions in the H3A.

To process image-sensor resolutions with more than 3008 pixels per line with no resolution loss, vertical frame division mode (FDM must be used); that is, the image must be divided into vertical chunks of less than 3008 pixels, and each chunk must be processed by the ISP sequentially. FDM is memory-to-memory processing and is not supported on the fly.

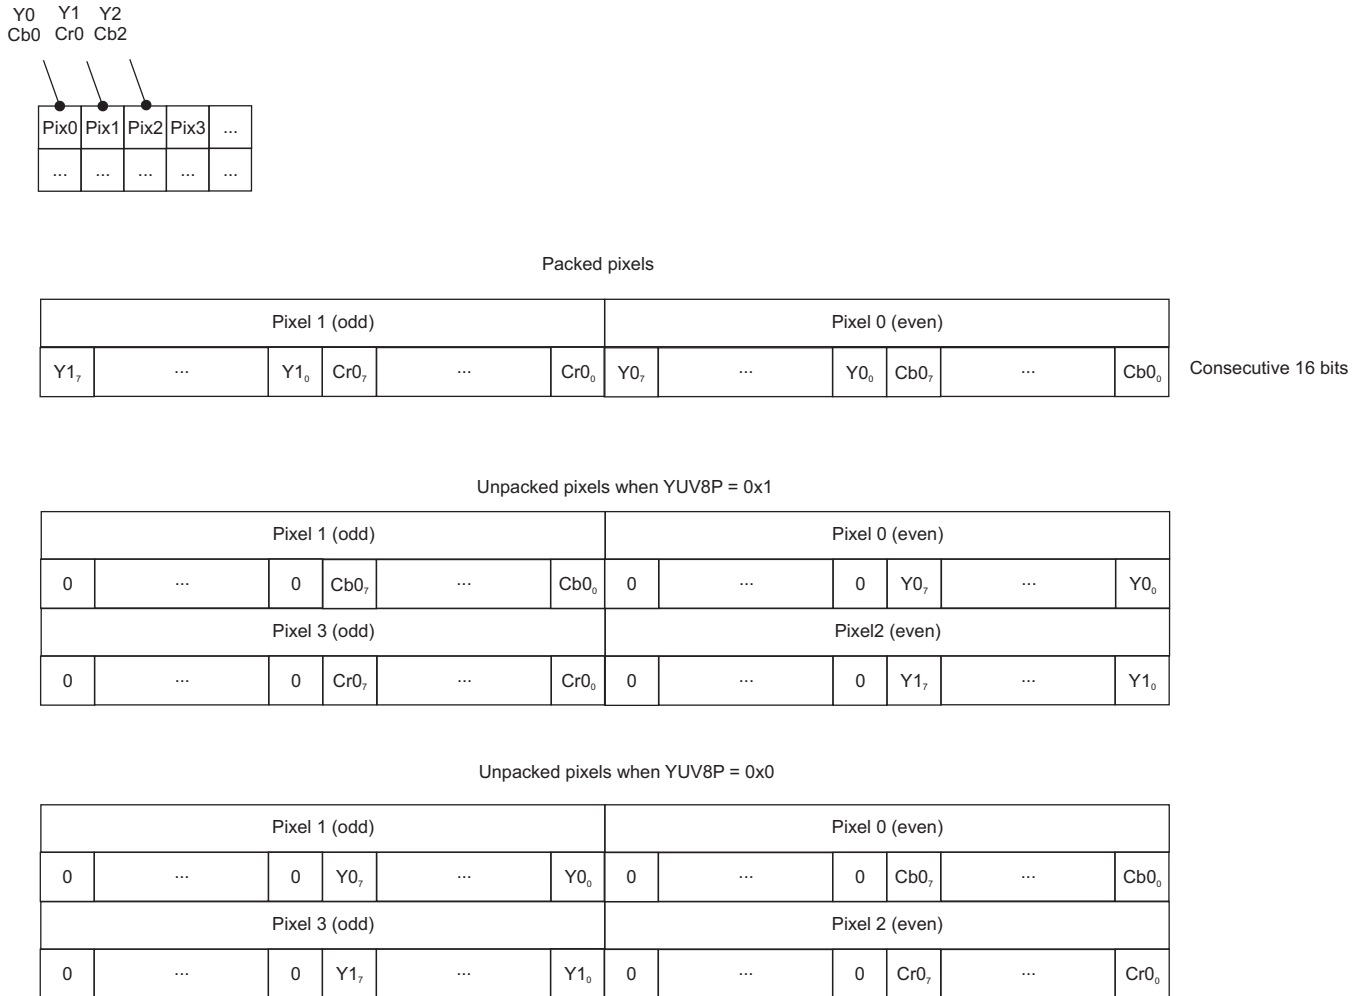

Alternatively, if loss of resolution is acceptable, the line width decimator (the [IPIPEIF_RSZ3A\[9\]](#) DECIM bit) can be enabled to downsample the input lines to a width equal to or less than the 3008 pixel maximum. The resize ratio (16/RSZ) can be configured by programming the [IPIPEIF_RSZ3A\[6:0\]](#) RSZ bit field to be within the range from 16 to 112 to give a resampling range from 1x to 1/7x.

When ALNSYNC is enabled ([IPIPEIF_INIRSZ3A\[13\]](#) ALNSYNC = 0x1), the [IPIPEIF_INIRSZ3A\[12:0\]](#) INIRSZ pixels are skipped (from the HD position) before the horizontal pixel decimator (see [Figure 8-124](#)).

8.3.3.3.13 ISS ISP IPIPEIF YUV4:2:2 8-bits packed Data Input Coming from ISIF Module

This section applies when data coming from the ISIF is 8 bits (`IPIPEIF_CFG2[6] YUV8 = 0x1`). When `IPIPEIF_CFG1[3:2] INPSRC2 = 0` and `IPIPEIF_CFG2[3] YUV16 = 1`, the 8-bit YUV data are transformed into 16-bit YUV data. The way the data are unpacked from 8 bits to 16 bits is controlled by the `IPIPEIF_CFG2[7] YUV8P` bit. See [Figure 8-125](#).

Figure 8-125. ISS ISP IPIPEIF YUV8P Settings

camss-616

8.3.3.3.14 ISS ISP IPIPEIF YUV4:2:0 Data Input for Memory-to-Memory Resize Operations

The ISP RSZ module can resize YUV4:2:0 data. The YUV4:2:0 data can come from the memory (through BL) or from the VP through the CCP2 RX module, which reads data from SDRAM and pushes it to the IPIPEIF module VP. The possible data paths are:

- SDRAM -> IPIPEIF (BL) -> RESIZER -> SDRAM
- SDRAM -> CCP2 RX -> IPIPEIF (VP) -> RESIZER -> SDRAM
- SDRAM -> IPIPEIF (BL) -> IPIPE -> RESIZER -> SDRAM
- SDRAM -> CCP2 RX -> IPIPEIF (BL) -> IPIPE -> RESIZER -> SDRAM

When the data comes from BL, the IPIPEIF module must be set up to process the luminance data first, and then the chrominance data.

- For 420Y (first pass):
 - `IPIPEIF_CFG1[15:14] INPSRC1 = 0x1` (SDRAM data input)

- IPIPEIF_CFG1[3:2] INPSRC2 = 0x1 (SDRAM data input)
- IPIPEIF_CFG1[13:11] DATASFT = 0x0 (no data shift)
- IPIPEIF_CFG1[9:8] UNPACK = 0x1 (data packed on 8 bits)
- IPIPEIF_CFG2[3] YUV16 = 0x1 (data_input [7:0] = 0 and data_input [15:8] = valid)
- For 420C (second pass):
 - IPIPEIF_CFG1[15:14] INPSRC1 = 0x1 (SDRAM data input)
 - IPIPEIF_CFG1[3:2] INPSRC2 = 0x1 (SDRAM data input)
 - IPIPEIF_CFG1[13:11] DATASFT = 0x0 (no data shift)
 - IPIPEIF_CFG1[9:8] UNPACK = 0x1 (data packed on 8 bits)
 - IPIPEIF_CFG2[3] YUV16 = 0x0 (data_input[7:0] = valid and data_input [15:8] = 0)

8.3.3.3.15 ISS ISP IPIPEIF Module Events and Status Checking

The IPIPEIF module generates an IPIPEIF event through the IPIPEIF_IRQ interrupt at the end of each frame. This interrupt is set through the [ISP5_IRQENABLE_SET_i\[9\]](#) IPIPEIF_IRQ bit. The input interrupt source generation is selected through the [IPIPEIF_CFG2\[0\]](#) INTSW bit in a certain configuration. The following pseudo code describes INTSW.

```
if (IPIPEIF_CFG2[0] INTSW==0) // Interrupt source from VP
  if (IPIPEIF_CFG1[15:14] INPSRC1==1,2 or 3)
    if (CFG1.ONESHOT==1) // In one shot mode
      Interrupt happens at the end of frame
    else // In continuous mode
      Interrupt is the start position of VD which is generated by IPIPEIF timing generator
  else // IPIPEIF_CFG1[15:14] INPSRC1==0, data is from VP
    Interrupt is the start position of VD from VP

else // Interrupt source from ISIF: IPIPEIF_CFG2[0] INTSW==1
  if (IPIPEIF_CFG1[3:2] INPSRC2==1,2 or 3)
    if (CFG1.ONESHOT==1) // In one shot mode
      Interrupt happens at the end of frame
    else
      Interrupt is the start position of VD which is generated by IPIPEIF timing generator
  else // IPIPEIF_CFG1[3:2] INPSRC2==0, data is from ISIF
    Interrupt is the start position of VD from ISIF
```

Moreover to this interrupt, the host must check the IPIPEIF_DTUF status flag of the [ISP5_IRQSTATUS_RAW2_i\[1\]](#) IPIPEIF_UDF bit (if this is enabled and mapped to the ISP IRQ lines) to see if an underflow occurred. For more information, see [Section 8.3.4.3.4](#).

8.3.3.4 ISS ISP IPIPE Functional Description

8.3.3.4.1 ISS ISP IPIPE Overview

- The input interface extracts valid region from the Bayer RAW data:
 - Up to 12-bit input pixel resolution
 - Requires at least 8 pixels for horizontal blanking and four lines for vertical blanking. In one-shot mode; 16 blanking lines after processing area are required.
 - Maximum horizontal and vertical offset of IPIPE processing area from synchronous signal is 65534.
 - Support RGB Bayer pattern for input
- DPC module fixes defect pixels using two methods: LUT-based and on-the-fly adaptive.
- 2D noise-filter module reduces noise in RAW data.
- Green-imbalance-correction (GIC) module reduces Gb/Gr difference to remove line crawl noise.
- White balance module applies offset and gain adjustments to each color.
- Color filter array (CFA) interpolation module implements CFA interpolation. The output from the CFA interpolation module is RGB-4:4:4 formatted data. CFA also reduces aliasing caused by undersampling by digital anti-aliasing (DAA)

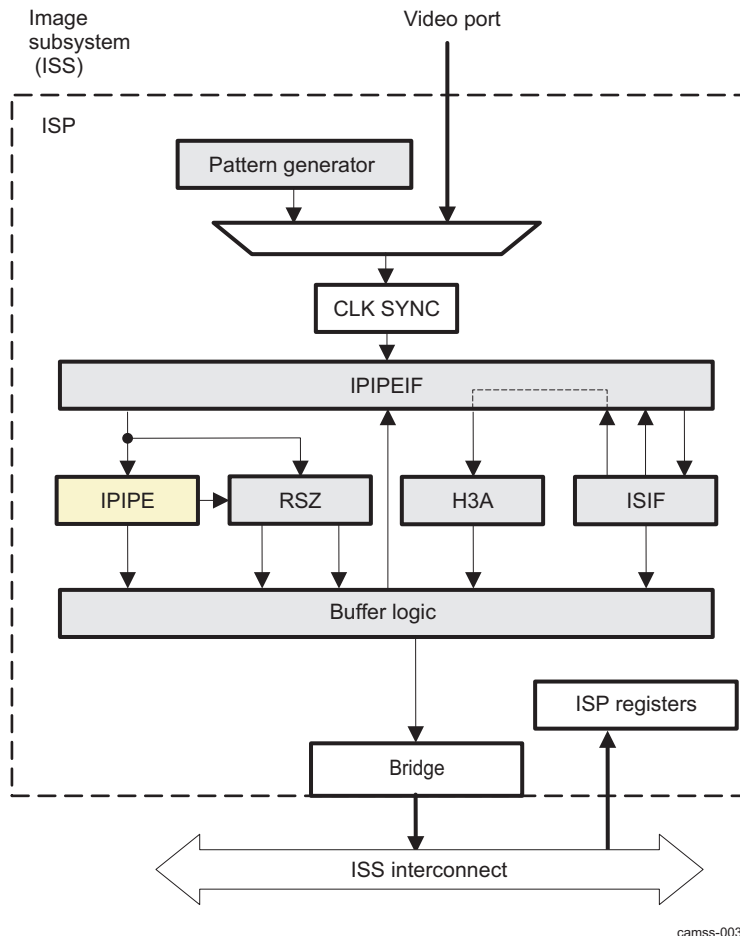

- RGB2RGB blending module applies a 3×3 matrix transform to the RGB data generated by the CFA interpolation module.
- Gamma correction module independently applies gamma correction to each RGB component. Gamma is implemented using a piece-wise linear interpolation approach with a 512-entry LUT for each color.
- 2nd RGB2RGB blending module applies a 3×3 matrix transform to the RGB data after gamma correction.
- 3D-LUT converts RGB data to RGB data using $9 \times 9 \times 9$ table and tetrahedral interpolation.
- RGB2YCbCr conversion module applies 3×3 matrix transformation to the RGB data to convert it to YCbCr data. This module also implements offset. Global brightness and contrast enhancement module fixes brightness and contrast tone.
- 4:2:2 conversion module applies the chroma low pass filter and downsampling to Cb and Cr to convert 4:4:4 data to 4:2:2 data.
- 2D edge enhancer module improves image clarity with luminance nonlinear filter.
- Chroma artifact reduction module reduces color artifacts using gain control and 2D median filter.
- Output interface module transfers data from IPIPE to SDRAM, in the form of one YCbCr (4:2:2 or 4:2:0), RGB (32/16 bits), or Bayer data.
- Histogram function can record histograms of up to four distinct areas into up to 256 bins.
- Boxcar function makes 1/8 or 1/16 size (1/64 or 1/256 in area) images.
- Boundary signal calculator (BSC) makes vectors of row and column summations.

IPIPE has four different processing paths:

- Case 1: IPIPE reads CCD RAW data and applies all IPIPE functions and stores the YCbCr (or RGB) data to SDRAM.
- Case 2: IPIPE reads CCD RAW data and stores the Bayer data after white balance to SDRAM.
- Case 3: IPIPE reads YCbCr-422 data and applies edge enhance, chroma suppression, and resize to output YCbCr data to SDRAM.
- Case 4: IPIPE reads YCbCr-420 data and applies resize to output YCbCr data to SDRAM.

[Figure 8-126](#) shows the connections from the IPIPE module to other submodules of the ISP.

Figure 8-126. ISS ISP IPIPE High-Level Diagram

8.3.3.4.2 ISS ISP IPIPE Top-Level Block Diagram

The IPIPE is a programmable hardware image-processing module that generates image data in YCbCr-4:2:2 or YCbCr-4:2:0 format from RAW CCD/CMOS data. The IPIPE module supports output of Bayer data.

The IPIPE module supports RAW data in Bayer format, as shown in [Figure 8-127](#). Other RGB formats or complimentary color formats are not supported.

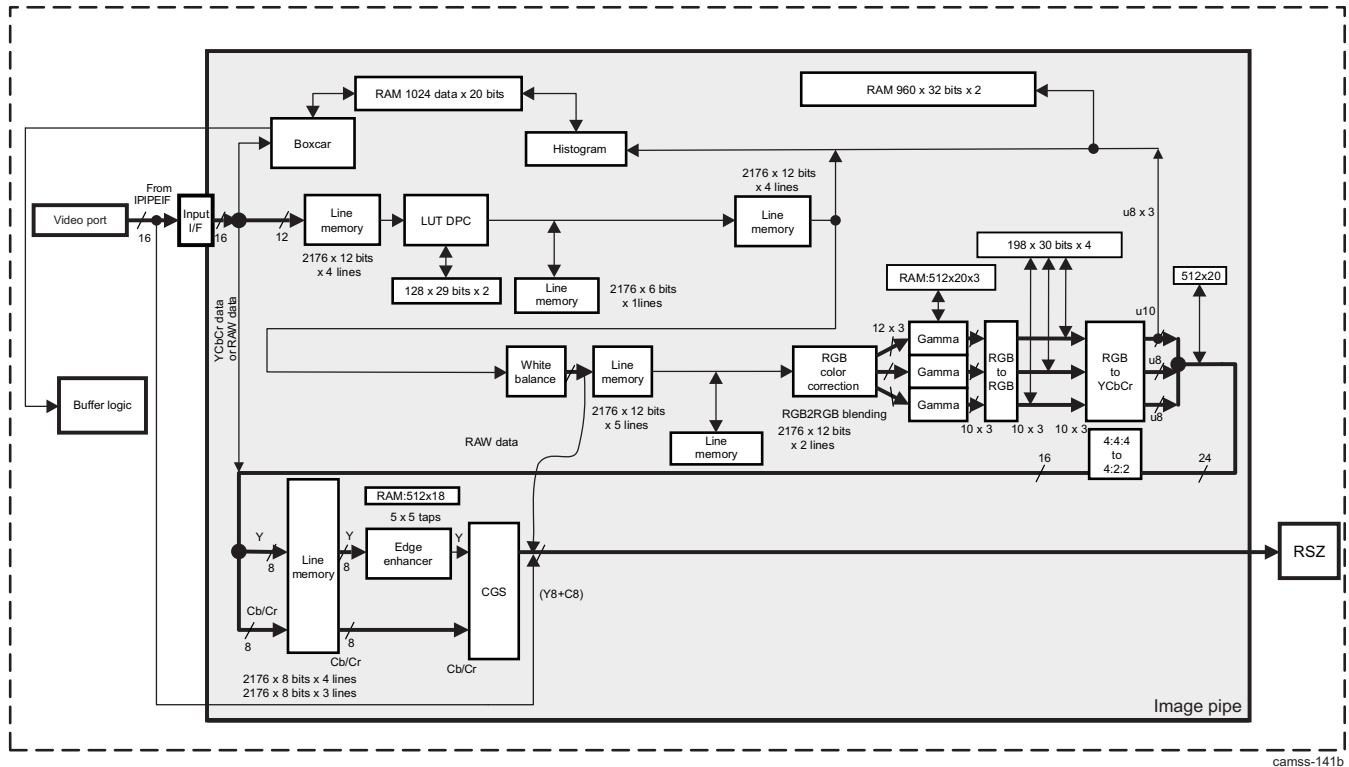

Figure 8-127. ISS ISP IPIPE Supported CFA Format

camss-142

As shown in [Figure 8-128](#), many internal modules are used to process Bayer data into YCbCr data

Figure 8-128. ISS ISP IPIPE Module Block Diagram

8.3.3.4.3 ISS ISP IPIPE Input Interface

The IPIPE module receives 12-bit RAW image data or 16-bit YCbCr data through the IPIPEIF module. The IPIPE module can work with up to 5376 pixels in each horizontal line, except in RAW pass-through mode. If the image width is larger than 5376, the image must be scaled down at the IPIPEIF module level. Otherwise, the input image must be split into several blocks.

If the input data is YCbCr, all RGB processing modules are skipped, and only edge enhancer and chroma suppression are applied to the input data.

If the input data is YCbCr-4:2:0, only Y or C can be processed at a time, and only resizer process can be applied. Because the resizer is outside the ISIF module, the data is passed to it directly by skipping the RGB and YCbCr processing modules.

In RAW pass-through mode, images up to 8190 pixels per line can be processed. In RAW pass through mode, the input data is written out directly to SDRAM.

The IPIPE module is enabled through the `IPIPE_SRC_EN[0]` EN bit.

The IPIPEIF module must be selected as the IPIPE module source with the `IPIPE_SRC_MODE[1]` WRT bit set to 1 from the input port of the IPIPEIF. This is required to enable and transfer data properly from the interface to the IPIPE.

The IPIPE module has two processing modes, which can be selected through the `IPIPE_SRC_MODE[0]` OST bit:

- One-shot mode: `IPIPE_SRC_MODE[0]` OST = 0x1
- Free-run mode: `IPIPE_SRC_MODE[0]` OST = 0x0

The input and output formats are selected in the `IPIPE_SRC_FMT[1:0]` FMT bit field (see Table 8-314).

Table 8-314. ISS ISP IPIPE Input and Output Selections

| IPIPE_SRC_FMT[1:0] FMT | IPIPE Module Input | IPIPE Module Output |
|-------------------------------|---------------------------|----------------------------|
| 0x0 | RAW Bayer | YCbCr or RGB |
| 0x1 | RAW Bayer | RAW Bayer |
| 0x2 | RAW Bayer | Disabled |
| 0x3 | YCbCr 16 bits | YCbCr |

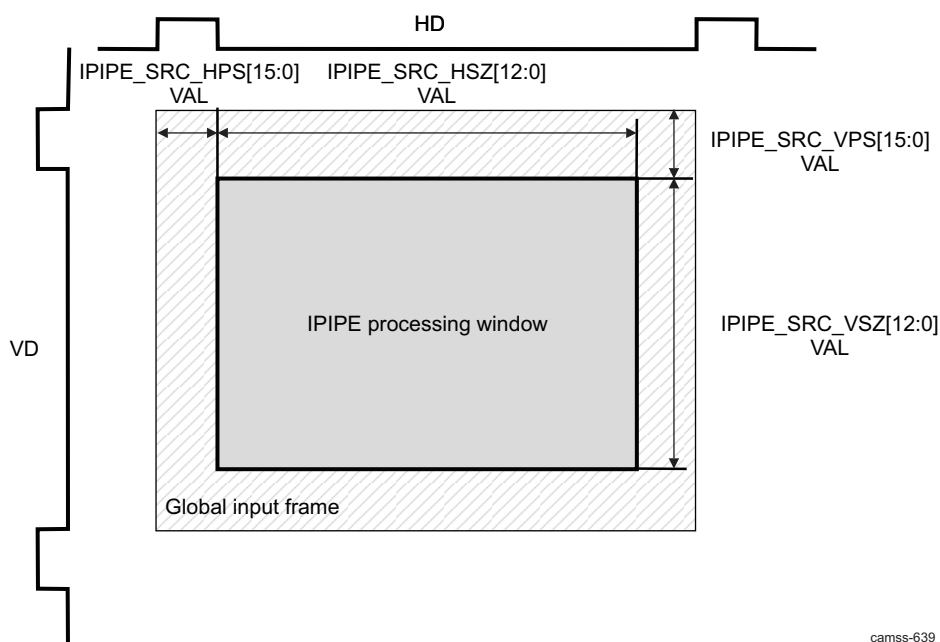

The input to the IPIPE module is in the formats (YCbCr-8bit is not allowed) shown in [Figure 8-129](#).

Figure 8-129. ISS ISP IPIPE Module Input Format

| IPIPE input | RAW YCbCr 16bit | LOW | LOW | LOW | LOW | RAW11 | RAW10 | RAW9 | RAW8 | RAW7 | RAW6 | RAW5 | RAW4 | RAW3 | RAW2 | RAW1 | RAW0 |
|-------------|-----------------|-----|-----|-----|-----|-------|-------|------|------|--------|--------|--------|--------|--------|--------|--------|--------|
| | | Y7 | Y6 | Y5 | Y4 | Y3 | Y2 | Y1 | Y0 | Cb/Cr7 | Cb/Cr6 | Cb/Cr5 | Cb/Cr4 | Cb/Cr3 | Cb/Cr2 | Cb/Cr1 | Cb/Cr0 |
| | Y 8bit | Y7 | Y6 | Y5 | Y4 | Y3 | Y2 | Y1 | Y0 | LOW | LOW | LOW | LOW | LOW | LOW | LOW | LOW |
| | CbCr 8bit | LOW | LOW | LOW | LOW | LOW | LOW | LOW | LOW | Cb/Cr7 | Cb/Cr6 | Cb/Cr5 | Cb/Cr4 | Cb/Cr3 | Cb/Cr2 | Cb/Cr1 | Cb/Cr0 |

camss-143

The window to process can be defined by its vertical and horizontal start position ([IPIPE_SRC_VPS](#) and [IPIPE_SRC_HPS](#)) and vertical and horizontal size ([IPIPE_SRC_VSZ](#) and [IPIPE_SRC_HSZ](#)). [Figure 8-130](#) shows the processing window settings.

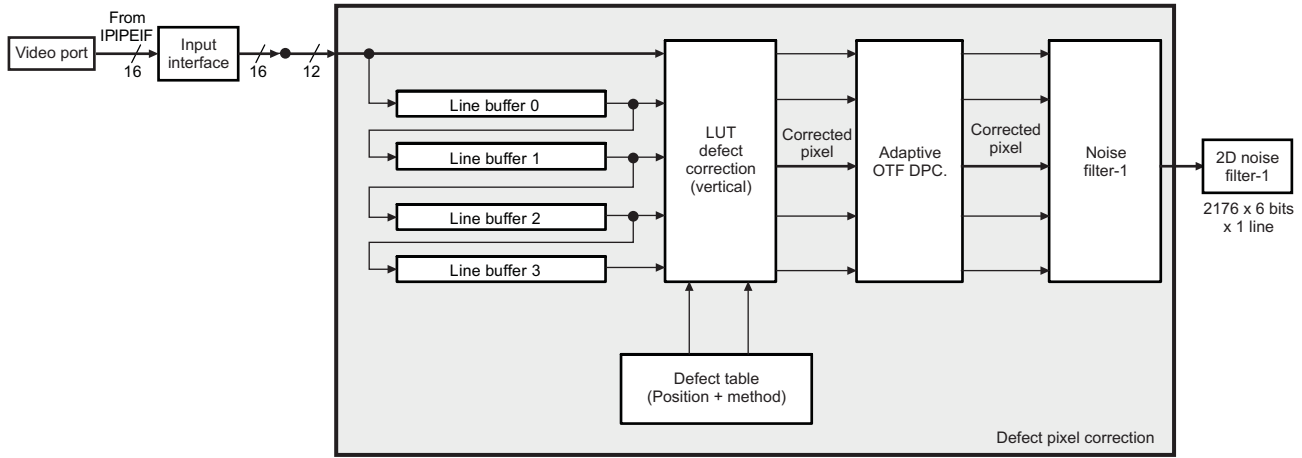

Figure 8-130. ISS ISP IPIPE Module Processing Window Settings

camss-639

8.3.3.4.4 ISS ISP IPIPE Defect Pixel Correction

The DPC module corrects defect pixels using two methods: look-up-table-based method (LUT DPC) and on-the-fly adaptive method (OTF DPC). [Figure 8-131](#) shows defect pixel correction.

Figure 8-131. ISS ISP IPIPE Defect Pixel Correction

camss-146b

8.3.3.4.1 ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

LUT DPC is the first stage of the IPIPE image-processing pipeline. The LUT DPC module corrects defects in input data. It supports up to a 256 defect point table. However, the table may be renewed as required during image processing. Therefore, the maximum amount of defect information is limited only by system level performance.

The module uses two sets of 128 x 29 memories to hold defect information. The table contains the information of horizontal position (13 bits), vertical position (13 bits), and correction method (3 bits), as shown in Table 8-315. The LUT DPC is enabled through the `IPIPE_DPC_LUT_EN[0]` EN bit.

Table 8-315. ISS ISP IPIPE Defect Information Packing

| Correction Method | Vertical Position | Horizontal Position |
|-------------------|-------------------|---------------------|
| 28..26 | 25..13 | 12..0 |

The information must be listed in the order of "from left to right" and "from the top to the bottom". The first position in the defect information table and the number of defects that are used may be specified. The address of the table must be programmed in the `IPIPE_DPC_LUT_ADR[9:0]` ADR bit field. Thus, the address of the first valid data is stated.

The LUT type can be:

- With a finite number of entries:
 - `IPIPE_DPC_LUT_SEL[1]` TBL = 0x0
 - The size of the LUT is set in the `IPIPE_DPC_LUT_SIZ[9:0]` SIZ bit field.
- With an infinite number of entries:
 - `IPIPE_DPC_LUT_SEL[1]` TBL = 0x1

The correction methods, set in Table 8-315, are described in Table 8-316.

Table 8-316. ISS ISP IPIPE Correction Method Description

| Correction Method | d0 = | Comment |
|-------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | Black or white dot | Replace with a black (or white) dot to force OTF-DPC to work on the pixel. White or black dot replacement can be selected through the <code>IPIPE_DPC_LUT_SEL[0]</code> DOT field. |
| 1 | d4 | Copy from left |
| 2 | d5 | Copy from right |

Table 8-316. ISS ISP IPIPE Correction Method Description (continued)

| Correction Method | d0 = | Comment |
|-------------------|-------------------------|--------------------------|
| 3 | $(d4 + d5)/2$ | Horizontal interpolation |
| 4 | $(d2 + d7)/2$ | Vertical interpolation |
| 5 | d2 | Copy from top |
| 6 | d7 | Copy from bottom |
| 7 | $(d2 + d4 + d5 + d7)/2$ | 2D interpolation |

The pixels in the defect correction algorithm are numbered as shown in [Figure 8-132](#).

Figure 8-132. ISS ISP IPIPE Pixel Numbering in Defect Correction Algorithm

camss-145

The pixels at the edges are mirrored in the way described in [Figure 8-133](#). The figure shows the typical correction by overwriting far edge pixels and mirroring them with other edge pixels. The example shows how by using a noise filter the correct-by-definition pixels are copied over bad pixels.

Figure 8-133. ISS ISP IPIPE Mirroring in Defect Correction and Noise Filter

(Right, top, and bottom edges have the same process.)

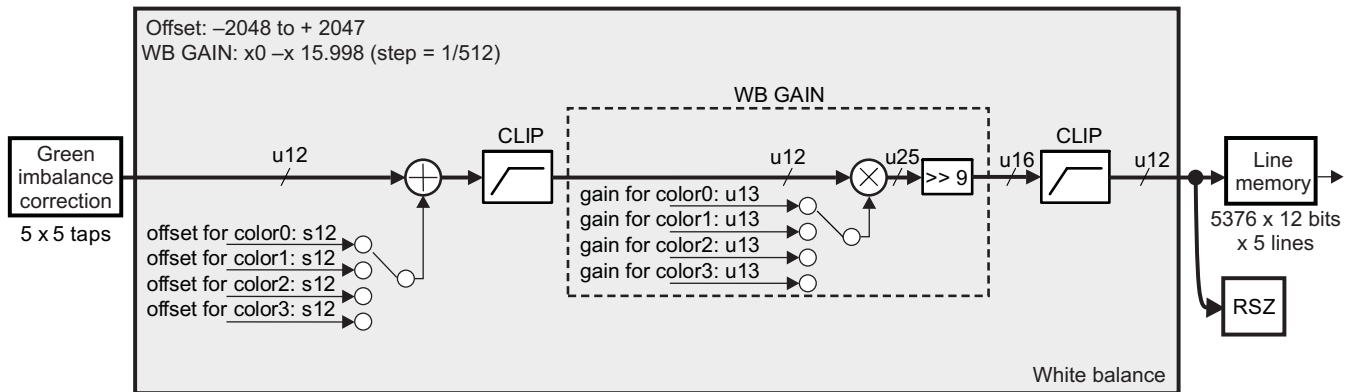

camss-147

8.3.3.4.5 ISS ISP IPIPE White Balance

The white balance module executes white balance to each color component. White balance gain adjusts the ratio of each color existing in a CFA pattern. An offset can be applied before white balance correction (IPIPE_WB2_OFT_R, GR, Gb, or B registers).

[Figure 8-134](#) is a block diagram of the white balance module. In the white balance gain adjuster, the RAW data is multiplied by a selected gain (IPIPE_WB2_WGN_R, Gr, Gb, or B registers) corresponding to the color. The white balance gain can be selected from four 13-bit values. Firmware can assign any combination of 4 pixels in horizontal and vertical directions. The precision of each gain is shown in the figure.

Figure 8-134. ISS ISP IPIPE White Balance

camss-155

8.3.3.4.6 ISS ISP IPIPE RGB2RGB Blending Module

The RGB2RGB blending module transforms the RGB data generated by the CFA interpolation module using a 3 x 3 square matrix transformation in combination with an added offset. The RGB to RGB blending is calculated using the formula shown in Figure 8-135. Each gain range is from -8 to +7.996 with step 1/256 = 0.004, and is set in the IPIPE_RGB1_MUL_RR to IPIPE_RGB1_MUL_BB registers. The offset range for each component is from -4096 to 4095, and is set in the IPIPE_RGB1_OFT_OR to IPIPE_RGB1_OFT_OB registers.

Figure 8-135. ISS ISP IPIPE RGB2RGB Conversion Formula

$$\begin{pmatrix} R_out \\ G_out \\ B_out \end{pmatrix} = \begin{pmatrix} gain_RR & gain_GR & gain_BR \\ gain_RG & gain_GG & gain_BG \\ gain_RB & gain_GB & gain_BB \end{pmatrix} \begin{pmatrix} R_in \\ G_in \\ B_in \end{pmatrix} + \begin{pmatrix} offset_r \\ offset_G \\ offset_B \end{pmatrix}$$

camss-650

8.3.3.4.7 ISS ISP IPIPE Gamma Correction Module

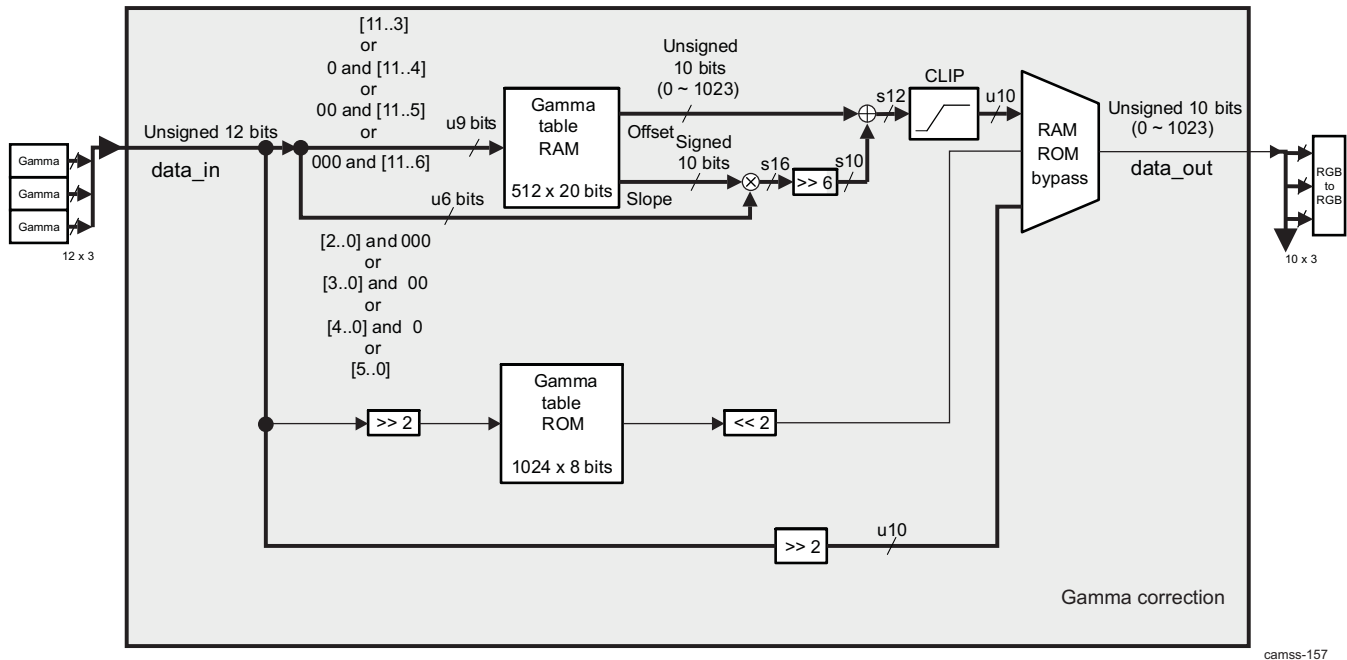

NOTE: For the memory access locations of the gamma correction module, see Section 8.3.3.9.

The gamma correction module performs a gamma correction independently for each color in the RGB color space by using a piece-wise linear interpolation. ROM tables and RAM tables are selectable through the IPIPE_GMM_CFG[4] TBL bit. Each ROM table and RAM table has 512-entries, and each entry accommodates a 10-bit offset and 10-bit slope. The range of slope value is from -512 to +511. The ROM table has 1024 entries and output 8-bit value.

Figure 8-136 is a block diagram of the gamma correction module. It is composed of two tables and one selector. When the BYPASS bit is asserted, the input data is divided by 16 (the IPIPE_GMM_CFG[0] BYPR, IPIPE_GMM_CFG[1] BYPG, and IPIPE_GMM_CFG[2] BYPB bits).

Figure 8-137 shows an example of the gamma curve. Figure 8-138 shows offset and slope packing.

Figure 8-136. ISS ISP IPIPE Gamma Correction Module Block Diagram

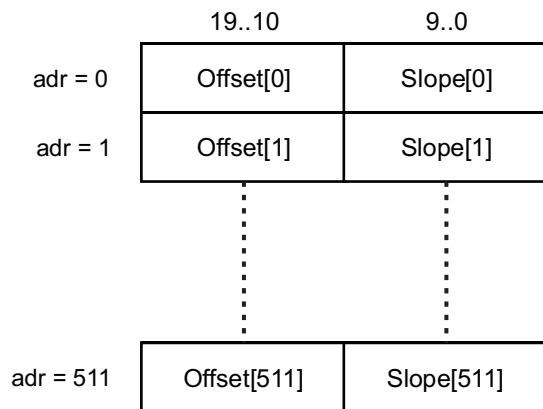

camss-157

Figure 8-137. ISS ISP IPIPE Gamma Curve Example

camss-158

Figure 8-138. ISS ISP IPIPE Gamma Table Offset/Slope Packing

camss-159

8.3.3.4.8 ISS ISP IPIPE 2nd RGB2RGB Conversion Matrix

The second RGB2RGB blending module transforms the RGB data after gamma correction using the 3 × 3 square matrix transformation in combination with an added offset. The RGB-to-RGB blending is calculated using the formula shown in Figure 8-139. Each gain range is from -4 to +3.996 with step 1/256 = 0.004 (s3.8), and is set in the IPIPE_RGB2_MUL_RR to IPIPE_RGB2_MUL_BB registers. The offset is -1024 to 1023 (s11), and is set in the IPIPE_RGB2_OFT_OR to IPIPE_RGB2_OFT_OB registers.

Figure 8-139. ISS ISP IPIPE RGB2RGB 2nd Conversion Formula

$$\begin{pmatrix} R_out \\ G_out \\ B_out \end{pmatrix} = \begin{pmatrix} gain_RR & gain_GR & gain_BR \\ gain_RG & gain_GG & gain_BG \\ gain_RB & gain_GB & gain_BB \end{pmatrix} \begin{pmatrix} R_in \\ G_in \\ B_in \end{pmatrix} + \begin{pmatrix} offset_r \\ offset_G \\ offset_B \end{pmatrix}$$

camss-650

8.3.3.4.9 ISS ISP IPIPE RGB2YCbCr Conversion Matrix

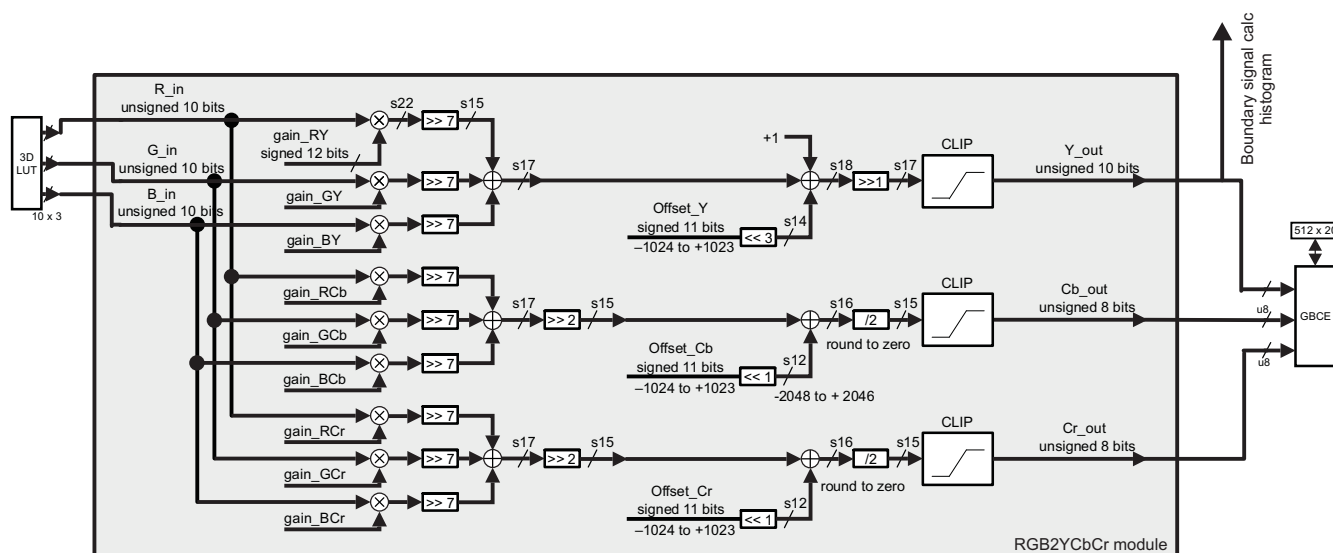

This module transforms the RGB data to YCbCr data format using a 3 × 3 matrix transformation in combination with an added offset. While transferring, the brightness control and contrast control can be adjusted using the IPIPE_YUV_ADJ[8:15] BRT and IPIPE_YUV_ADJ[8:15] CRT bit fields, respectively. Then, the transform is calculated using the formula shown in Figure 8-140. Each gain range is from -8 to +7.996 with step 1/256 = 0.004, configured in the IPIPE_YUV_MUL_RY to IPIPE_YUV_MUL_BCr registers. The offset is -1024 to 1023 for Y, Cb, and Cr, configured in the IPIPE_YUV_OFT_Y to IPIPE_YUV_OFT_Cr registers. Figure 8-141 is the block diagram of the RGB to RGB blending module. The output is calculated by the equation.

Figure 8-140. ISS ISP IPIPE RGB2RGB 2nd Conversion Formula

$$\begin{pmatrix} Y_out \\ Cb_out \\ Cr_out \end{pmatrix} = \begin{pmatrix} gain_RY & gain_GY & gain_BY \\ gain_RCb & gain_Gcb & gain_BCb \\ gain_RCr & gain_GCr & gain_BCr \end{pmatrix} \begin{pmatrix} R_in \\ G_in \\ B_in \end{pmatrix} + \begin{pmatrix} offset_Y \\ offset_Cb \\ offset_Cr \end{pmatrix}$$

camss-654

Figure 8-141. ISS ISP IPIPE RGB2YCbCr Module Block Diagram

camss-161

8.3.3.4.10 ISS ISP IPIPE 4:2:2 Conversion Module

The 4:2:2 conversion module converts the image data to YCbCr-4:2:2 format by taking the average of every two Cb and Cr components. Y and Cb/Cr sampling point of spatial cosited or spatial centering are selectable using the `IPIPE_YUV_PHS[0]` POS register. Horizontal 3 taps and 4- or 2-tap filters are used for spatial cosited and spatial centering, respectively. The module is enabled from the `IPIPE_YUV_PHS[1]` PLF bit.

Figure 8-142. ISS ISP IPIPE Chroma Subsampling Position

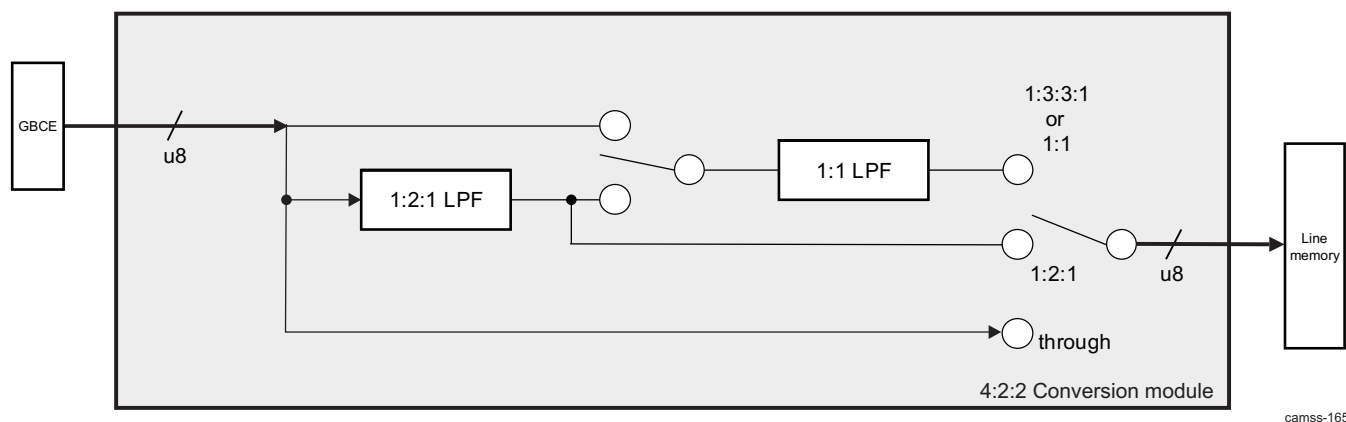

Figure 8-143 is a block diagram of the 4:2:2 conversion module.

Figure 8-143. ISS ISP IPIPE 4:2:2 Conversion Module Block Diagram

8.3.3.4.11 ISS ISP IPIPE 2D Edge Enhancer

NOTE: For the location of 2D edge-enhancer memory accesses, see [Section 8.3.3.9](#).

The edge-enhancer module operates on the luminance (Y data) component of images to improve the image quality and can be enabled from the `IPIPE_YEE_EN[0]` EN bit. Edges in input images are detected by a 2D high-pass filter, and its sharpness is increased by the value from a non-linear table. [Figure 8-144](#) shows a block diagram of the luminance non-linear edge-enhancer. Entry for the non-linear table is 10-bit and the output is in signed 9-bit.

In edge-enhancer mode when `IPIPE_YEE_TYP[0]` SEL is set to 0, linear filter with programmable coefficient is applied to the Y input. Here, M is a 5×5 matrix with programmable coefficients (`IPIPE_YEE_MUL_xx`, where $x = 00, 01, 02, 10, 11, 12, 20, 21, 22$). A down shift of high pass filter is applied to the edge enhancer from the `IPIPE_YEE_SHF[3:0]` SHF bit field (shgHPF in the formula).

Then, the HPF value is shrunk by a threshold value (u6) specified by the `IPIPE_YEE_THR` register (thresholdHPF in the formula), and clipped to signed 10 bits to get the index for the LUT.

Figure 8-144. ISS ISP IPIPE 2D Edge-Enhancer Indexing

$$index = clip(\text{shrink}(HPF, threshold_{HPF}), -512, 511)$$

$$\text{shrink}(x, threshold) = \begin{cases} x + threshold & x < -threshold \\ 0 & -threshold \leq x \leq threshold \\ x - threshold & threshold < x \end{cases}$$

$$\text{clip}(x, limit_{LOW}, limit_{HIGH}) = \begin{cases} -limit_{LOW} & x < -limit_{LOW} \\ x & -limit_{LOW} \leq x \leq limit_{HIGH} \\ limit_{HIGH} & limit_{HIGH} < x \end{cases}$$

camss-661

Moreover, the edge-enhancement intensity is looked up from the LUT through the formula shown in [Figure 8-145](#) and in [Table 8-317](#).

Figure 8-145. ISS ISP IPIPE 2D Edge Intensity LUT Formula

$$E_{int} = LUT[index]$$

camss-662

Table 8-317. ISS ISP IPIPE Edge-Enhancer LUT Mapping

| Address (32-bit Word Address) | Bit Position | LUT Index |
|-------------------------------|--------------|-----------|
| 0x00000h | 8 .. 0 | 1 |
| | 17 .. 9 | 2 |
| 0x00001h | 8 .. 0 | 2 |
| | 17 .. 9 | 3 |
| 0x00002h | 8 .. 0 | 4 |
| | 17 .. 9 | 5 |
| 0x00003h | 8 .. 0 | 6 |
| | 17 .. 9 | 7 |
| ⋮ | ⋮ | ⋮ |
| | ⋮ | ⋮ |
| 0x000FFh | 8 .. 0 | 510 |
| | 17 .. 9 | 511 |

| | 17 .. 9 | -1 |

Figure 8-146 shows the LUT packing, and Figure 8-147 shows the 2D edge-enhancer block diagram.

Figure 8-146. ISS ISP IPIPE 2D Edge-Enhancer LUT Packing

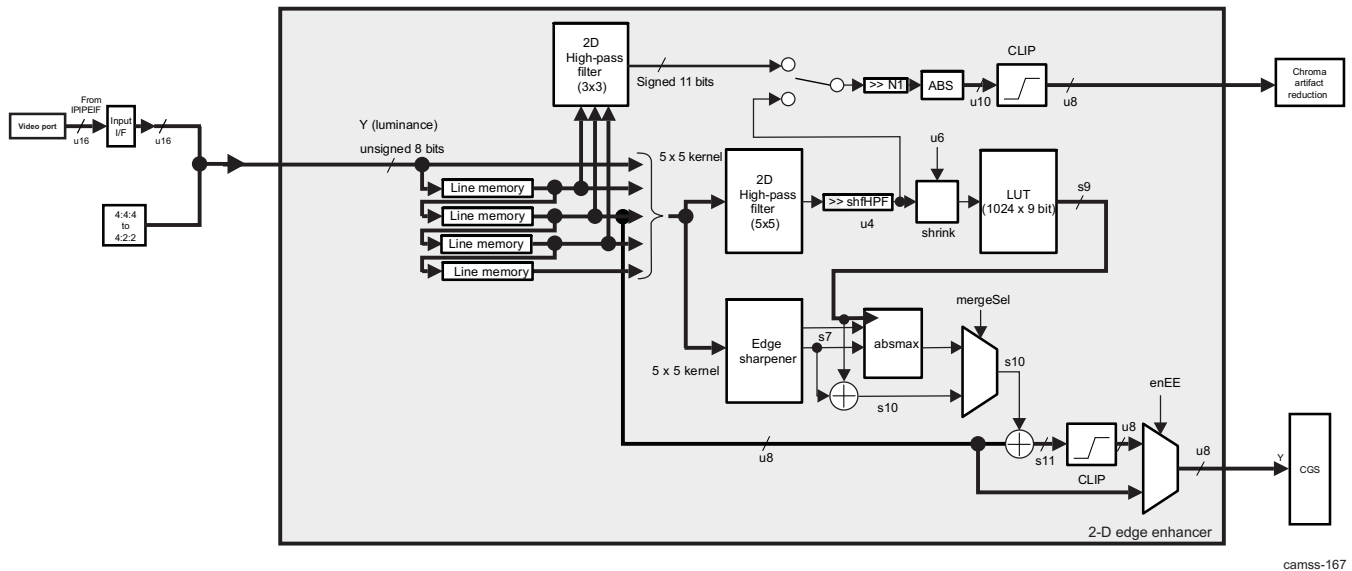

Figure 8-147. ISS ISP IPIPE 2D Edge-Enhancer Block Diagram

In edge sharpener mode, enabled when `IPIPE_YEE_TYP[0] SEL = 1`, edge clarity is enhanced without producing a Halo artifact. In this module, edge intensity is derived by the 2D linear filter with fixed coefficients shown in Figure 8-148.

Figure 8-148. ISS ISP IPIPE Edge Sharpener Details

$$S_{i,j} = \begin{pmatrix} 0 & -1 & -2 & -1 & 0 \\ -1 & 0 & 2 & 0 & -1 \\ -2 & 2 & 8 & 2 & -2 \\ -1 & 0 & 2 & 0 & -1 \\ 0 & -1 & -2 & -1 & 0 \end{pmatrix}$$

$$sharpness(h,v) = clip \left(shrink \left(g \times \left(\sum_{j=-2}^2 \sum_{i=-2}^2 S_{i,j} Y(h+i,v+j) \right) \gg 3, threshold_{LOW} \right) \gg 6, -threshold_{HIGH}, threshold_{HIGH} \right)$$

camss-663

The gain (g) and threshold values for the shrink/clip function (threshold_{LOW}, threshold_{HIGH}) are determined by the [IPIPE_YEE_E_GAN](#), [IPIPE_YEE_E_THR_1](#) and [IPIPE_YEE_E_THR_2](#) registers. The bit width of g and threshold_{HIGH} is in U6, and threshold_{LOW} is in U12Q6.

This edge intensity is then clipped by a threshold value in the formula shown in [Figure 8-149](#).

Figure 8-149. ISS ISP IPIPE 2D Edge-Intensity Clipping Formula

$$S_{int} = \begin{cases} clip(sharpness, -grad, grad) & \text{Halo reduction on} \\ sharpness & \text{Halo reduction off} \end{cases}$$

camss-664

The threshold value (grad) is a function of the activity around the target pixel, which is derived from gradient values. Gain and offset are specified by [IPIPE_YEE_G_GAN](#) and [IPIPE_YEE_G_OFT](#)

Capping with gradient value prevents overly enhancing edges, and suppresses halo artifacts around edges.

The output from edge enhancer and edge sharpener are merged with the function shown in [Figure 8-150](#).

Figure 8-150. ISS ISP IPIPE 2D Edge Enhancer and Sharpener Merger Formula

$$E_{merge} = \begin{cases} E_{int} + S_{int} & IPIPE_YEE_TYP[0]SEL = 0 \\ absmax(E_{int}, S_{int}) & IPIPE_YEE_TYP[0]SEL = 1 \end{cases}$$

$$absmax(x, y) = \begin{cases} x & abs(y) \leq abs(x) \\ y & otherwise \end{cases}$$

camss-666

The E_{merge} value is added to the Y input value to make the final output.

For chroma suppression, another 2D high pass filter (HPF) is implemented. One of the four coefficient sets shown in [Figure 8-151](#) is selectable.

Figure 8-151. ISS ISP IPIPE 2D Edge Chroma-Suppression Coefficient Sets

$$\begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 0 & 0 \\ 1 & -2 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \begin{pmatrix} 0 & 1 & 0 \\ 0 & -2 & 0 \\ 0 & 1 & 0 \end{pmatrix}, \text{ or } \begin{pmatrix} 0 & 1 & 0 \\ 1 & -4 & 1 \\ 0 & 1 & 0 \end{pmatrix}$$

camss-667

At the end of the edge enhancer process, brightness and contrast adjustment are applied to the Y signal. The formula shown in [Figure 8-152](#) describes the process.

Figure 8-152. ISS ISP IPIPE 2D Edge-Brightness and Contrast Adjustments Formula

$$Y_{ctr_brt} = clip8(clip8((Y_{EE} \times CTR) \gg 4) + BRT)$$

$$clip8(x) = \begin{cases} x & x \leq 255 \\ 255 & 255 < x \end{cases}$$

camss-668

In the formula from [Figure 8-184](#), Y_{EE} is the output (Y) of the Edge-Enhancer, as shown in [Figure 8-147](#), CTR is a U8Q4 contrast enhancement factor (configured through the [IPIPE_YUV_ADJ\[7:0\]](#) CTR bit field), BRT is a U8 brightness enhancement factor (configured through the [IPIPE_YUV_ADJ\[15:8\]](#) BRT bit field), and YCTR_BRT is the output with brightness and contrast adjustment applied.

8.3.3.4.12 ISS ISP IPIPE Histogram

NOTE: The boxcar function can be used simultaneously with the histogram function if needed.

NOTE: For the locations of histogram memory access, see [Section 8.3.3.9](#).

The histogram module counts the number of pixels that have a value in a region and can be enabled from the `IPIPE_HST_EN[0]` EN bit. Moreover, if enabled, the `IPIPE_HST_MODE` register can be set to work constantly or one time. If the `IPIPE_HST_MODE[0]` OST bit is set to 1, the histogram is disabled by clearing the `IPIPE_HST_EN[0]` EN bit to 0 after one run (one-shot mode).

After enabling the module, the following features are available:

- The data to be summed is taken from the DPC memory or RGB2YCbCr module. The choice is made in the `IPIPE_HST_SEL[2]` SEL bit.
- When data are collected from the DPC memory, the sampled colors are R/G/B/Y. Y is derived in the following method:

$$Y = (\text{HST_MUL_R} * R + \text{HST_MUL_GR} * Gr + \text{HST_MUL_GB} * Gb + \text{HST_MUL_B} * B) \quad (4)$$
 For the G histogram, Gb, Gr, or the average is used, through the `IPIPE_HST_SEL[1:0]` TYP bit field.
- Two sets of 512 × 20-bit memory are used.
- The number of bins can be set from 32 to 256 in the `IPIPE_HST_PARA[13:12]` BIN bit field.
- The number of regions (areas) from 1 to 4; each region can be enabled through `IPIPE_HST_PARA[x]` RGNx (where x = 0 to 3). The positions of the regions are defined in `IPIPE_HST_x_VPS` and `IPIPE_HST_x_HPS`, and the vertical and horizontal size are defined by `IPIPE_HST_x_VSZ` and `IPIPE_HST_x_HSZ`, respectively (where x = 0 to 3).
- The number of regions × the number of bins ≤ 256.
- Each region can be turned on/off counting.
- The regions have priority orders.
- Each region has its own start coordinate X/Y (12 bits) and horizontal/vertical sizes (12 bits)
- When regions are overlapped, the value in the overlapped region is accumulated only in the region with the highest priority.
- The number of colors to be counted is from 1 to 4. Each color in all regions can be turned off counting (the `IPIPE_HST_PARA[7:4]` bit field).
- The value of each pixel is down-shifted (0 ~ 11) before counting using the `IPIPE_HST_PARA[11:8]` SHF bit field.
- When the value of a bin reaches ($2^{20} - 1$), the value is saturated until the memory is cleared.
- Number of bins: 32, 64, 128, or 256

The histogram memory can be cleared at the VD signal. When the memory is cleared, the first line of each frame cannot be sampled by the histogram if the width of the frame is larger than 512. If the width of the frame is smaller than 512, the first ceil (512/width) lines cannot be collected, where ceil(x) is the smallest integer value above x. If the clearing function is not enabled, the histogram bins are accumulated over the previous values.

The histogram has two banks of memories, which can be switched alternatively. The two memory banks are slipped into four histogram memory tables. Only two tables can be used at a time: output memory tables 0 and 1, or tables 2 and 3. To initialize tables, the `IPIPE_HST_TBL[1]` CLR bit is set to 1, and to select which set of tables is to be used the `IPIPE_HST_TBL[0]` SEL bit can be switched between 0 and 1.

A gain for each color can be applied using the `IPIPE_HST_MUL_x` registers, where x = R, GR, GB, or B.

8.3.3.4.13 ISS ISP IPIPE Boxcar

The boxcar module generates a boxcar by taking mosaic image data and averaging the red, green, and blue pixels in an (8 × 8) or (16 × 16) block to produce one red, green, and blue output, as shown in [Figure 8-153](#) and in [Figure 8-154](#). Here, similar to the histogram module, the boxcar is enabled from the `IPIPE_BOX_EN[0]` EN bit, and if the mode is set to run once (one shot) (`IPIPE_BOX_MODE[0]` OST = 1), the enable bit is cleared after the run. The size of the blocks is determined from the `IPIPE_BOX_SHF[0]` SEL bit, where if set to 0 = 8 × 8, and 1 = 16 × 16.

The result of this operation is a full-color image with (1/64) or (1/256) area of the original image. The maximum input horizontal width is 8190 pixels when a 16 × 16 block is used; the width is 4096 when an 8 × 8 block is used. Also, the image size (width and height) must be multiple of 16 for a 16 × 16 block, and multiple of 8 for an 8 × 8 block. Boxcar operation works on 12-bit Bayer data and outputs 16-bit data. The output data is 48-bit RGB data for each 8 × 8 or 16 × 16 block. The 48-bit data is aligned in 64-bit format in SDRAM as shown in Section 8.3.3.4.13. The first address of SDRAM access is specified by the `IPIPE_BOX_SDR_SAD_H` and `IPIPE_BOX_SDR_SAD_L` registers. The output data are written to SDRAM continuously line by line; there is no address offset between lines. After the image transfer of each frame completes, the `ipipe_eof` signal is sent to buffer logic. This signal is issued at the same timing as `ipipe_int_dma`.

Figure 8-153. ISS ISP IPIPE Boxcar Operation (8 × 8 Block)

Figure 8-154. ISS ISP IPIPE Boxcar Operation (16 × 16 Block)

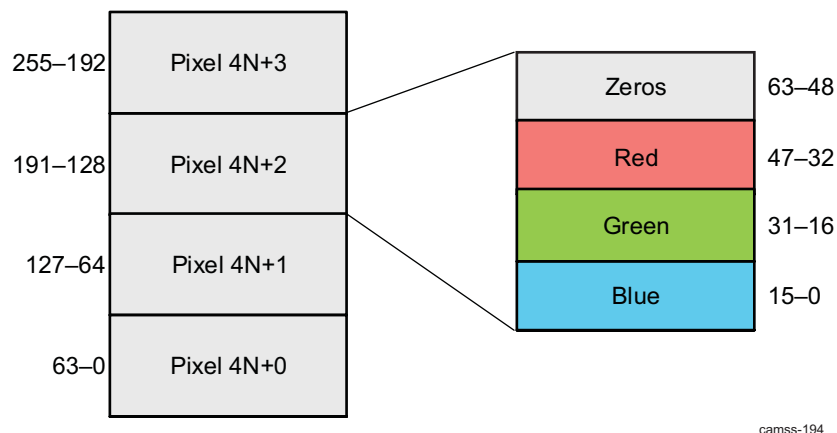

Figure 8-155. ISS ISP IPIPE Boxcar Data Packing in SDRAM

camss-194

The right shift value is specified by the `IPIPE_BOX_SHF` register, which has a range of 0 to 4. (The shift down is performed to fit the 20-bit accumulated value into 16-bit output.) For green signal processing, a divide-by-two operation rounds off the least-significant bit (LSB).

8.3.3.5 ISS ISP RSZ Functional Description

8.3.3.5.1 ISS ISP RSZ Overview

The RSZ module rescales images into various sizes ranging from x1/4096 scale-down to x16 scale-up. It also works in conjunction with the rotational engine (ROT) in SIMCOP for rotating images. The RSZ data slave interfaces support a parallel video port (VP). The RSZ module can produce two output images simultaneously, because there are two independent resizer engines. The input data used by the two resizer engines is the same.

The RSZ module has the following capabilities:

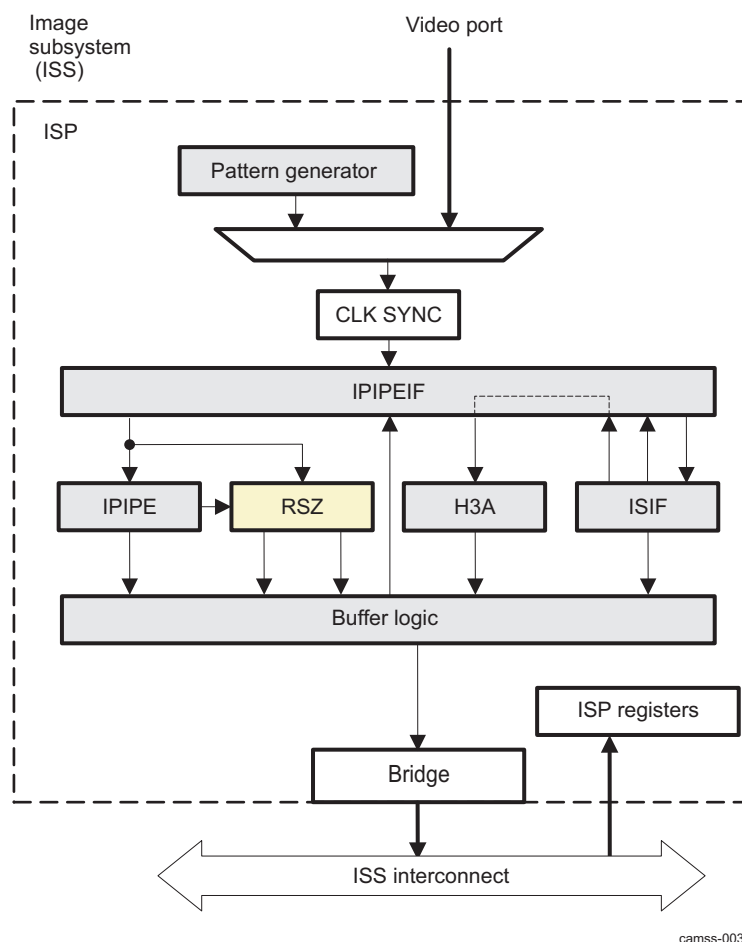

- Input/output data formats:
 - Common input data for the two resizers
 - Independent output data formats for the two resizers
 - Supports YUV4:2:2 input and then supports YUV4:2:2/YUV4:2:0 or RGB5:6:5/ARGB32 output.
 - Output rates up to 200 MPix/s for YUV4:2:2/YUV4:2:0 or RGB5:6:5 output
 - Output rates up to 160 MPix/s for ARGB32 output
 - Supports YUV4:2:0 input data and then supports only YUV4:2:0
 - YUV4:2:0 input format not supported natively
 - Two passes required: luma followed by chroma or vice versa
 - Input and output rates up to 100 MPix/s in this configuration (YUV4:2:0)
 - Only supported from memory to memory
 - Supports RAW Bayer input and RAW Bayer output
 - RAW format invariant. Takes whichever RAW format at the input and writes it out unmodified: 16 bits are read, 16 bits are written out.
 - No resizing can take place on RAW data.
- Resizer capabilities:
 - Input image cropping
 - Common for the two resizer engines: Same input data before and after cropping
 - Supported on YUV4:2:2 and RAW data formats
 - Supported on pass-through mode data path
 - Supported on bypass mode data path

- Dual resizer engines: RSZ-A and RSZ-B
 - Up to x20 upsampling and x1/4096 downsampling on both engines
 - Up to 200-MHz pixel throughput on both resizer engines
 - Programmable data rate control to smooth the peak memory bandwidth
- RSZ-A
 - Horizontal resolution of up to 8K pixels on RSZ-A.
- RSZ-B
 - Horizontal resolution of up to 8K pixels on resizer RSZ-B
- Independent Y and Cb/Cr phases on horizontal and vertical axis
 - Enables to take care of different YUV4:2:0 phases used in different video formats
 - Enables frame division mode: Images can be stitched together with the right phase.
- Rescaling: two modes supported
 - Normal mode for upscale and downscale: Higher flexibility but lower downscale quality
 - Downscale mode for downscale only: Lower flexibility but higher downscale quality
- Filtering: two modes supported
 - Independent settings for the horizontal and vertical directions
 - 3-tap low pass filter with 2-tap linear interpolation
 - 4-tap cubic interpolation
- Flip support of the output image
 - Horizontal flip
 - Vertical flip
- Pixel duplication on the top/bottom, left/right sides
 - Avoids losing pixels at the image boundaries because of the filtering
- Support pass-through and bypass modes: Resizer engines bypassed
 - Pass-through mode
 - RAW and YUV4:2:2 data support
 - Lower power consumption mode to transfer data to memory
 - Can transfer images larger than 8K pixels to memory
 - Bypass mode
 - RAW and YUV4:2:2 data support
 - Input buffer used. Can benefit from additional buffering in case the BL module memory is not big enough and back pressure occurs.
- Slave data interface: VP interface
 - Two VP interfaces: The programming model selects which VP is used to input data to the RSZ module. Both VPs cannot be active simultaneously.
 - VP 1: Typically connected to the IPIPE module.
 - VP 2: Typically connected to the IPIPEIF module.
 - Up to 200-MHz pixel clock
- Master data interface:
 - Two interfaces to the BL module
 - Up to 200 MHz
 - 32-bit wide, 32-byte long requests
 - Accesses are aligned on 32-byte boundaries
 - Used to transfer data to memory
 - Each interface is dedicated to a single output image.
 - Addressing modes

- Linear
- Circular
- Configuration interface:
 - Up to 100 MHz
 - 32-bit wide
 - Used to configure the resizer registers
- Power management:
 - Independent clock domains for the two resizers
 - Each resizer engine can be gated off separately
- Error management:
 - FIFO overflow detection on the input buffers

Figure 8-156 show the RSZ module connections to other submodules of the ISP.

Figure 8-156. ISS ISP RSZ High-Level Diagram

8.3.3.5.2 ISS ISP RSZ Top-Level Block Diagram

Figure 8-157 is the top-level block diagram of the RSZ module. The RSZ module comprises the following submodules: cropping, input data buffering, data requestor, averager, data saturation, and resizer Interpolation (comprised of horizontal rescaler, vertical rescaler, color conversion, and output interface) (see the following sections for more information).

The RSZ module comprises two independent resizer engines with the same capabilities (except for the memory line size). The input data can come from VP 1 or VP 2. Software must determine and control which interface is selected.

The RSZ module includes one VBUSP slave port, which is used to control the RSZ registers. It also includes two MTC master ports, which are used to pass the pixels to the BL. The BL in turn creates the burst requests to the memory subsystem (see Section 8.3.3.5.3, *ISS ISP RSZ Interfaces*).

Figure 8-157. ISS ISP RSZ Top-Level Block Diagram

camss-402

8.3.3.5.3 ISS ISP RSZ Interfaces

The RSZ module has the following data interfaces:

- One 32-bit read/write point-to-point pending VBUSP interface
- Two slave VP interfaces for transport YUV and RAW data
- TWO MTC interfaces to BL for RZA A and RZA B, with only write capabilities

8.3.3.5.3.1 ISS ISP RSZ VBUSP interface

The VBUSP interface is a 32-bit read/write capable interface. The VBUSP interface must be programmed in a way that back-to-back requests are possible for read and write. The `RSZ_GCK_MMR[0]` MMR bit enables the memory register access from the VBUSP interface to enable transfer and signal such as MMR request, direction, enable write/read data can be enabled.

8.3.3.5.3.2 ISS ISP RSZ Video Port Interfaces

The VP interfaces are slave interfaces; one is connected to IPIPE, and the other to IPIPEIF. These interfaces are for data transfer. Table 8-318 lists the format supported across IPIPE/IPIPEIF and RSZ. Signals coming from IPIPE and IPIPEIF can be write-enable signals. The `RSZ_SRC_MODE[1]` WRT bit is set whether or not the write enable signals are considered. This is a line-valid qualifier. This signal is sampled on the rising edge of HD, and the value is used for the full line.

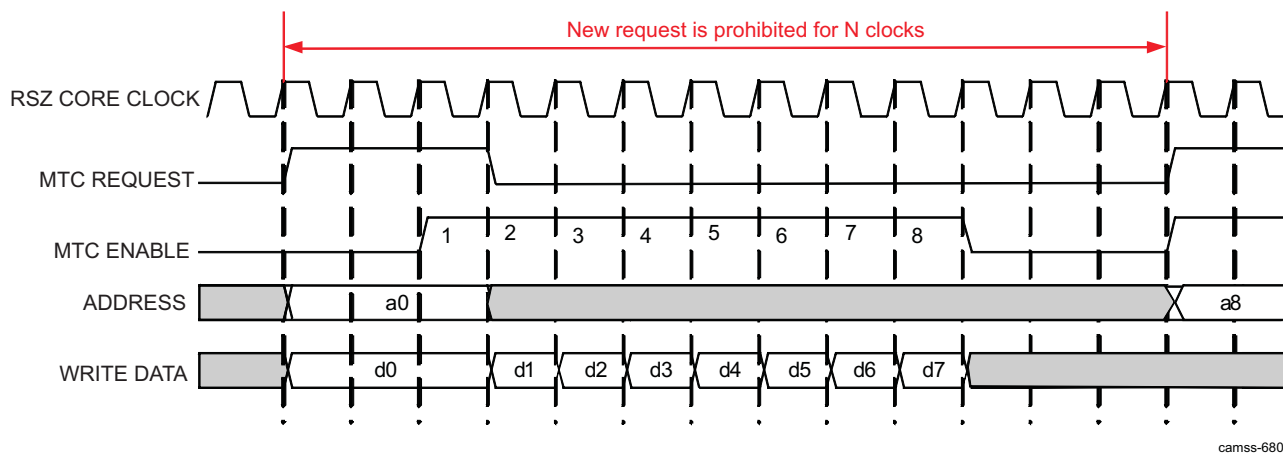

Table 8-318. ISS ISP RSZ VP Supported Formats

| | VP Signals: From IPIPE and IPIPEIF Modules (dat[15:0] Register) | | | | | | | | | | | | | | | |
|-------------------------------|-----------------------------------------------------------------|-----|-----|-----|-----|-----|-----|-----|------------|------------|------------|------------|------------|------------|------------|------------|
| | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| RAW16 | R15 | R14 | R13 | R12 | R11 | R10 | R9 | R8 | R7 | R6 | R5 | R4 | R3 | R2 | R1 | R0 |
| YUV4:2: 2 16 bits | Y7 | Y6 | Y5 | Y4 | Y3 | Y2 | Y1 | Y0 | Cb7 Cr7 | Cb6 Cr6 | Cb5 Cr5 | Cb4 Cr4 | Cb3 Cr3 | Cb2 Cr2 | Cb1 Cr1 | Cb0 Cr0 |
| YUV4:2: 0 Y data | Y7 | Y6 | Y5 | Y4 | Y3 | Y2 | Y1 | Y0 | Low | Low | Low | Low | Low | Low | Low | Low |
| YUV4:2: 0 Cb/Cr data | Low | Low | Low | Low | Low | Low | Low | Low | Cb7 Cr7 | Cb6 Cr6 | Cb5 Cr5 | Cb4 Cr4 | Cb3 Cr3 | Cb2 Cr2 | Cb1 Cr1 | Cb0 Cr0 |

NOTE: The formats are set from the IPIPE and IPIPEIF registers. For more information, see [Section 8.3.3.4](#) and [Section 8.3.3.3](#).

8.3.3.5.3.3 ISS ISP RSZ MTC interfaces

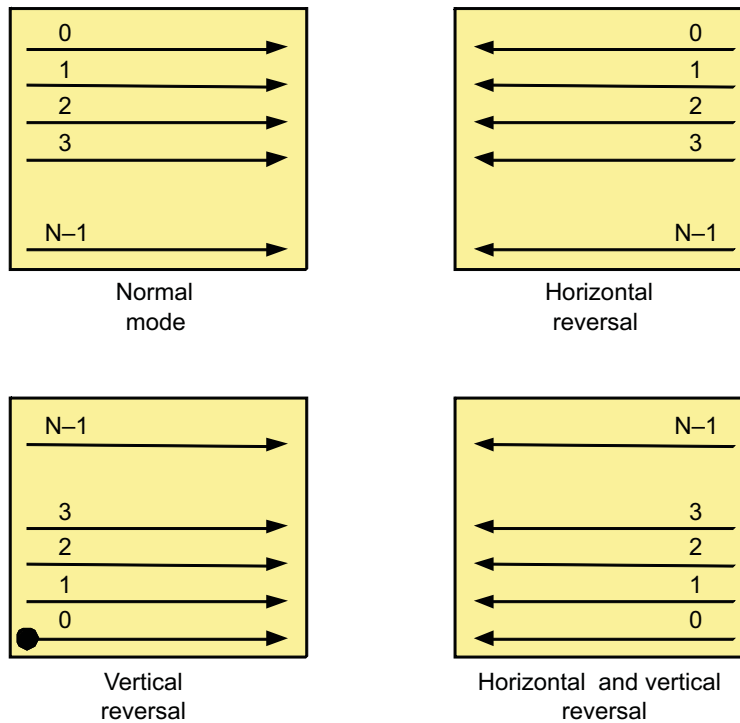

The RSZ module includes two write-only MTC interfaces. Their implementation enables passing a maximum of eight 32-byte requests in ten clock cycles. The RSZ must be programmed to obtain smooth and average bandwidth to buffer logic module by setting a minimum interval between two successive requests (set the `RSZ_DMA_RZA[15:0]` RZA and `RSZ_DMA_RZB[15:0]` RZB bit fields for the A and B resizers as appropriate). This setting is not expected to be dynamic. It can be fixed setting from request to request and frame to frame. When the bandwidth is set appropriately, between the first valid translated pixel and the EOF signal sent to buffer logic, the `RSZ_DMA_STA[0]` STATUS bit can be seen, and it is high if the transfer over the MTC interfaces is active. [Figure 8-158](#) shows how `RSZ_DMA_RZx` for resizers A and B affects the MTC data request generator.

Figure 8-158. ISS ISP RSZ MTC DMA Bandwidth Control

camss-680

[Figure 8-159](#) shows the pixel order in memory written by the MTC. The arrows do not represent the order in which data is written. Data are always written from left to right, whether horizontal reversal is enabled or not.

Figure 8-159. ISS ISP RSZ MTC Image Data Storage Pixel Order

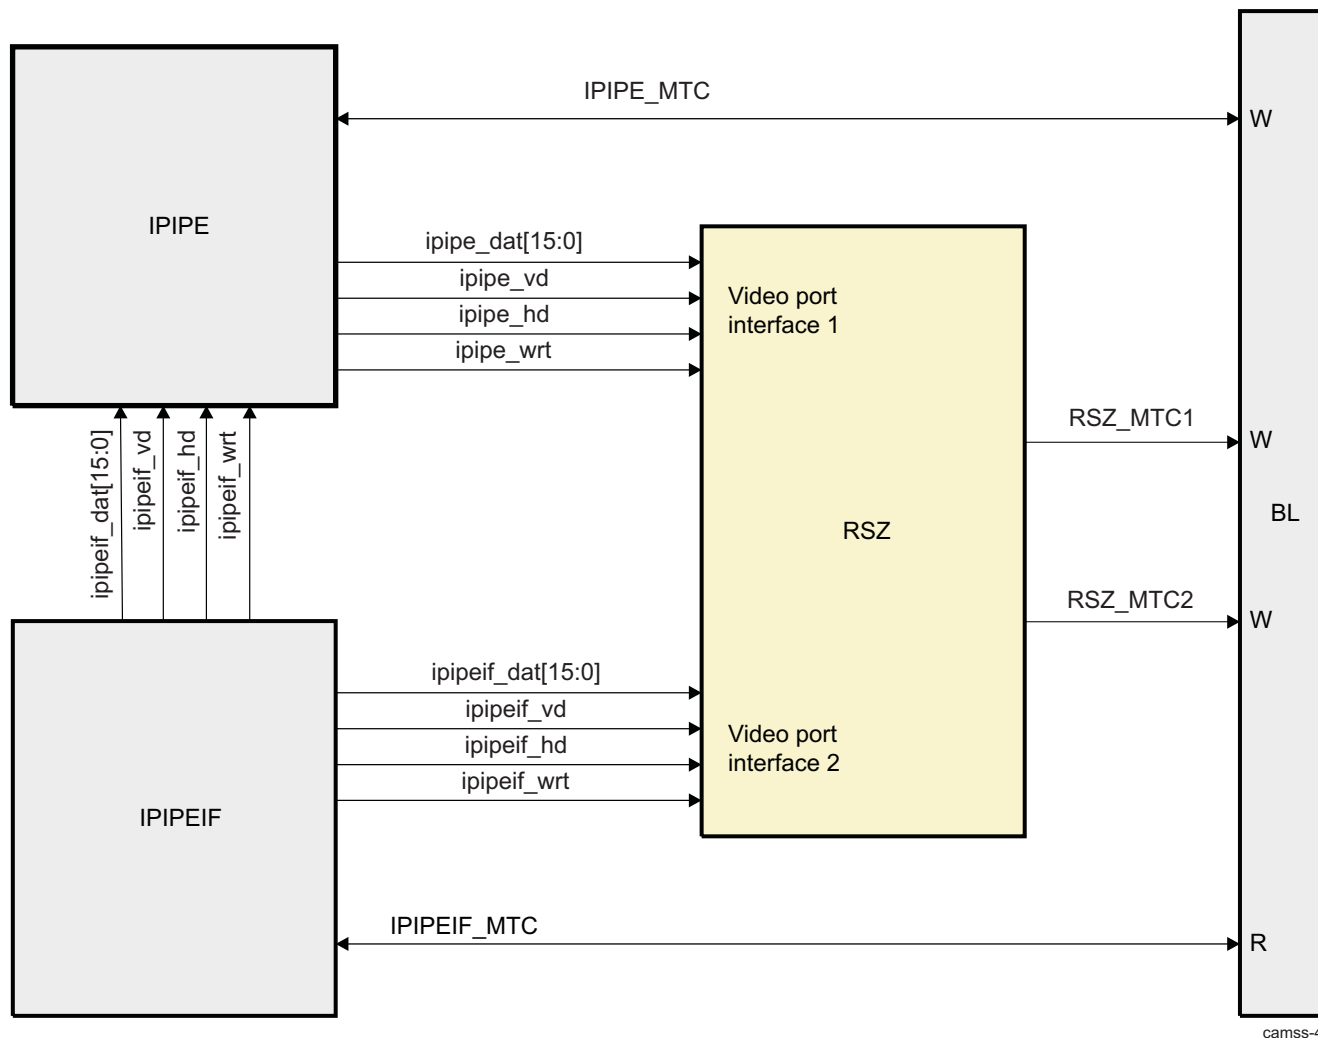

camss-684

The RSZ MTC interfaces can be stalled by the input MTC STALL signal. The assertion of the MTC STALL signal is a result of a hardware mechanism that is monitoring the CBUFF module to prevent its overflow. When this signal is asserted, the current 32-byte MTC request is finished and then the RSZ MTC output ports are stalled. For details on the output ports, see [Section 8.3.3.5.5.7, ISS ISP RSZ Output Interface](#).

8.3.3.5.4 ISS ISP RSZ Integration

[Figure 8-160](#) shows how the VP and interfaces of the RSZ module are connected to surrounding modules at the ISP level. The RSZ module gets data from the IPIPEIF module or IPIPE module.

Figure 8-160. ISS ISP RSZ Typical Module Integration: High-Level Summary

The following constraints apply to the RSZ module:

- The data coming from the IPIPEIF module can be RAW or YUV4:2:2 data. Because the RSZ module can rescale only YUV4:2:2 data, the RSZ module must be configured in pass-through mode when RAW data is received on VP 2. It is possible to bypass the RSZ engine if YUV4:2:2 data is sent but rescaling is not needed (bypass mode).
- The data coming from the IPIPE module can be RAW or YUV4:2:2 data. Eventually, YUV4:2:0 data can be sent through this path, but the data must be sent in two passes. Because the RSZ module can rescale only YUV4:2:2 data, the RSZ module must be configured in pass-through mode when RAW data is received on VP 1. It is possible to bypass the RSZ engine if YUV4:2:2 data is sent but rescaling is not needed (bypass mode).

VP 2 provides a way to bypass the IPIPE module when YUV4:2:2 data is received from the images sensor or when YUV4:2:2 is read back from memory with the CCP2 RX or ISIF module.

[Table 8-319](#) summarizes the different RSZ configuration possibilities as a function of the input data format.

Table 8-319. ISS ISP RSZ Data Flow vs. Input Data Format Constraints

| VP 1 Data Format | VP 2 Data Format | RSZ-A Configuration | RSZ-B Configuration | Comments |
|------------------|------------------|---------------------|---------------------|------------------------------------------------|
| RAW | N/A | Disabled | Disabled | RSZ module in pass-through mode or bypass mode |

Table 8-319. ISS ISP RSZ Data Flow vs. Input Data Format Constraints (continued)

| VP 1 Data Format | VP 2 Data Format | RSZ-A Configuration | RSZ-B Configuration | Comments |
|------------------|------------------|---------------------|---------------------|------------------------------------------------|
| N/A | RAW | Disabled | Disabled | RSZ module in pass-through mode or bypass mode |
| YUV4:2:2 | N/A | Disabled | Disabled | RSZ module in pass-through mode or bypass mode |
| YUV4:2:2 | N/A | Enabled | Disabled | One output image |
| YUV4:2:2 | N/A | Disabled | Enabled | One output image |
| YUV4:2:2 | N/A | Enabled | Enabled | Two output images |
| N/A | YUV4:2:2 | Disabled | Disabled | RSZ module in pass-through mode or bypass mode |
| N/A | YUV4:2:2 | Enabled | Disabled | One output image |
| N/A | YUV4:2:2 | Disabled | Enabled | One output image |
| N/A | YUV4:2:2 | Enabled | Enabled | Two output images |

8.3.3.5.5 ISS ISP RSZ Functional Description

To start up, the RSZ configuration can be set from the [RSZ_SYSCONFIG](#) register, which provides enabling the RSZ-A and RSZ-B clocks. The RSZ module does not have standalone reset and status check. Software reset must be done at the ISP level. Moreover, when enabled, the RSZ module can control the input data buffer, and when the `rsz_stall_input` signals are set from the [RSZ_IN_FIFO_CTRL](#) register, the RSZ module generates a stall signal that can be used by the master module sending data to the RSZ module when the data threshold is too high.

The [RSZ_SRC_EN\[0\]](#) EN bit starts the resizer processing. If the processing mode is set to one shot (one run and then turn off) from the [RSZ_SRC_MODE\[0\]](#) OST bit, the EN bit is cleared to 0.

The resizer can be configured to be bypassed in certain cases (see [Figure 8-160](#) for the module constraints) from the [RSZ_SRC_FMT0\[1\]](#) BYPASS bit. The data can be sent directly from here to the output interface (bypass mode) or imported to the module buffer, but not manipulated and sent to the output interface (pass-through mode). The master device sending data to the resizer can be switched between IPIPEIF and IPIPE using the [RSZ_SRC_FMT0\[0\]](#) SEL bit. The resizer understanding of the data input is set from the [RSZ_SRC_FMT1](#) register (for more information, see [Table 8-321](#)). The [RSZ_SEQ.VRVX](#) and [RSZ_SEQ.HRVX](#) registers can be set to flip the image horizontally or vertically, respectively (see [Figure 8-159](#)).

Depending on the mode to which the resizer is set, the core clock can be enabled from the [RSZ_GCK_SDR](#) register. [Table 8-320](#) summarizes the behavior of the module for the different settings.

Table 8-320. ISS ISP RSZ Module Modes: Register Settings

| Configuration Number | RSZ_SRC_EN | RZA_EN | RZA_CLK_EN | RZB_EN | RZB_CLK_EN | RSZ_GCK_SDR_CORE | RSZ_SRC_FMT0.BYPASS | Comments |
|----------------------|------------|--------|------------|--------|------------|------------------|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | 0 | X | X | X | X | X | X | Data cannot go through the RSZ module. Interrupts are not issued. |
| 1 | 1 | 0 | X | 0 | X | 1 | 0 | Resizer A is disabled. Resizer B is disabled. It is best to have <code>RZA_EN = RZB_EN = 0</code> to save power, but <code>RZA_EN = RZB_EN = 1</code> is also supported. |
| 2 | 1 | 1 | 1 | 0 | X | 1 | 0 | This configuration is supported but does not make sense because data cannot go through the module. Resizer A is enabled. Resizer B is disabled. |

Table 8-320. ISS ISP RSZ Module Modes: Register Settings (continued)

| | | | | | | | | |
|---|---|---|---|---|---|---|---|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| | | | | | | | | It is best to have RZB_EN = 0 to save power, but RZB_EN =1 is supported as well. |
| 3 | 1 | 0 | X | 1 | 1 | 1 | 0 | Resizer A is disabled. Resizer B is enabled. |
| 4 | 1 | 1 | 1 | 1 | 1 | 1 | 0 | It is best to have RZA_EN = 0 to save power, but RZA_EN = 1 is also supported. Resizer A is enabled. Resizer B is enabled |
| 5 | 1 | X | X | X | X | 0 | 0 | Bypass mode is enabled. Resizer core functional clock is disabled. |
| 6 | 1 | X | X | X | X | 0 | 1 | Pass-through mode enabled. Resizer core functional clock is disabled. |
| 7 | 1 | X | X | X | X | 1 | 1 | Pass-through mode is enabled. Resizer core functional clock is enabled. |
| | | | | | | | | Not a preferred configuration. Configuration (6) saves power. |

Table 8-321. ISS ISP RSZ Module Input Control: Register Settings

| RSZ_SRC_FMT1.IN420 | RSZ_SRC_FMT1.COL | Comments |
|------------------------------------|----------------------------------|------------------------------------------------------------------------------------------|
| 0 | X | YUV4:2:2 input. Chrominance is cosited. |
| 1 | 0 | YUV4:2:0 input. Valid data is Y, C is dummy. On the VP, YUV4:2:2 data is always assumed. |
| 1 | 1 | YUV4:2:0 input. Valid data is C, Y is dummy. On the VP, YUV4:2:2 data is always assumed. |

The [RSZ_YUV_PHS\[0\]](#) POS bit sets the chrominance output. The RSZ module does not change the relative position of the chroma samples versus the luma samples between the input and output, and the chroma position at the output of the IPIPE module and at the output of the RSZ module must be identical. In other words, [RSZ_YUV_PHS.POS](#) = [IPIPE_YUV_PHS.POS](#).

Settings are common for both resizer engines inside the RSZ module. Each engine (RZA or RZB) can be enabled from the [RZx_EN](#) register: select the mode from [RZx_MODE](#), and select the input and output in the YUV color scheme from the [RZx_420](#) register (valid only if YUV 4:2:2 is the input set from [RSZ_SRC_FMT1.IN420](#)). [Table 8-322](#) summarizes the combination of settings available in the [RZx_420](#) register.

Table 8-322. ISS ISP RSZ-A/RSZ-B Output Format Selection

| RZx_420.YEN | RZx_420.CEN | Comments |
|-----------------------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | 0 | Input is YUV4:2:2. Output is YUV4:2:2 if RZX_RGB_EN = 0 and RGB if RZB_RGB_EN = 1. |
| 0 | 1 | Input is YUV4:2:2. Output is the chroma of YUV4:2:0. RZX_RGB_EN is ignored. Must be used to rescale YUV4:2:0 data: 1st/2nd pass |
| 1 | 0 | Input is YUV4:2:2. Output is the luma of YUV4:2:0. RZX_RGB_EN is ignored. Must be used to rescale YUV4:2:0 data: 2nd/1st pass |
| 1 | 1 | Input is YUV4:2:2. Output is YUV4:2:0. RZX_RGB_EN is ignored. |

8.3.3.5.1 ISS ISP RSZ Operating Modes

The RSZ module offers two basic rescaling modes. These modes are not built-in but are particular configurations, which means that other hybrid modes can be programmed. The normal mode provides more flexibility (the rescale ratio granularity is smaller) than downscale mode, but downscale mode produces better image quality (averager performs anti-aliasing):

- Normal mode: The scaling process is carried out using interpolation with a 4-tap filter. The interpolation method is a 4-tap cubic convolution or a 3-tap linear filter + 2-tap linear interpolation. The user controls the type of interpolation that is used. The possible rescale ratios range from 1/16x to 20x.
- Downscale mode: The scaling process is the same as for normal mode, but an averaging function is placed before. It enables reaching much higher reduction factors while avoiding anti-aliasing artifacts. The interpolation method is a 4-tap cubic convolution or a 3-tap linear filter + 2-tap linear interpolation. The possible rescale ratios range from 1/4096x to 1x.

NOTE: The selection of the mode is independent for each resizer engine. One resizer engine can be configured in normal mode, while another is configured in downscale mode.

The RSZ module can produce two output images simultaneously, because there are two independent resizer engines. The input data used by the two resizer engines is the same. The RSZ output image sizes are limited to `RSZ_GNC[0:12]` `RSZA_MEM_LINE_SIZE` pixels/line for RSZ-A (5376 pixels/line) and `RSZB_MEM_LINE_SIZE[16:28]` for RSZ-B (2336 pixels/line).

Figure 8-161 shows the RSZ operating modes. Note that nothing prevents to use linear interpolation in normal mode or bicubic interpolation in downscale mode, similarly, one may want to mix the interpolation modes for horizontal and vertical filtering. This is fully programmable.

Figure 8-161. ISS ISP RSZ Operating Modes

8.3.3.5.5.1 ISS ISP RSZ Operating Modes and Maximum Input Clock

The maximum output pixel clock on both resizers is 200 MHz (100 percent optimal power performance [OPP]), that is, a pixel throughput of 200 MPix/s. Moreover, hardware takes care of the following constraints:

- When both resizer engines are configured to perform downscaling, there is no particular constraint on the VP pixel clock. The VP pixel clock can be as high as 200 MHz.
- When one resizer engine is configured to perform upscaling and the second resizer engine is configured to perform downscaling, the VP pixel clock must be limited. The VP must be lower than:

$$\text{clk_pix} \leq (200 \text{ MHz} / (\text{Vertical Upscale Ratio} * \text{Horizontal Upscale Ratio})) \tag{5}$$

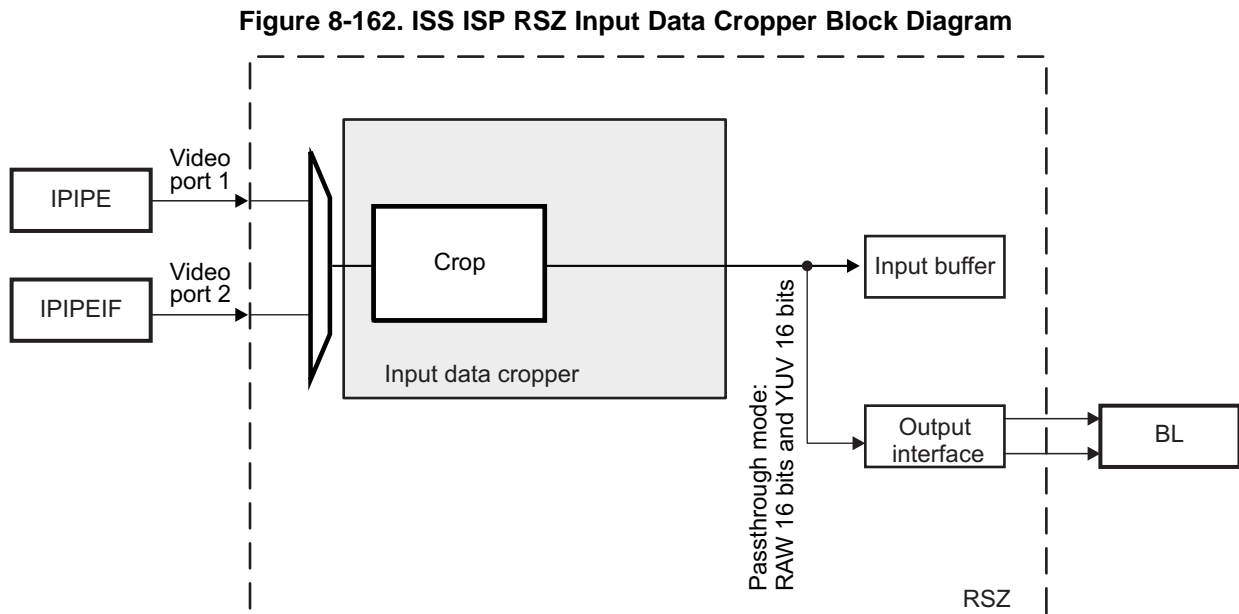

For example, if a 4x upscale ratio happens horizontally and vertically, then the input pixel clock must be lower than $200 / (4 * 4) = 12.5$ MHz.

It is the reason why it is not possible to perform digital zoom upscaling on the fly. It is necessary to acquire the pixels to memory first and to read them back at a pace that does not exceed the previously discussed constraints. At the ISS level, data can be read back from memory from the CCP2 RX or ISIF module.

- When the two resizer engines are configured to perform upscaling, the VP pixel clock must be limited. In that case, the VP frequency is limited by the resizer engine having the larger rescale ratios.

8.3.3.5.2 ISS ISP RSZ Input Data Cropper

The data coming from the VPs into the RSZ module can be cropped: this applies to RAW and YUV4:2:2 data. It is mandatory to crop the data as early as possible in the RSZ processing pipeline to reduce power consumption. It is mandatory to crop the data before storing it in the input data buffer. [Figure 8-162](#) is the block diagram of the RSZ input data cropper.

camss-708

The input data are in YUV4:2:2 interleaved format or RAW format.

For YUV4:2:2 format, the data come as Cb0, Y0, Cr0, Y1, Cb2, Y2, Cr2, Y3, etc. Y denotes the luma component value and Cb/Cr denotes the chroma component values. There are as many Y components as Cb/Cr components per line.

[Figure 8-163](#) shows input data cropping. Only the cropped data is stored in the input data buffer. The names used in the figure correspond to the register names. If no cropping is desired, the [RSZ_SRC_HPS](#) and [RSZ_SRC_VPS](#) registers, which set the horizontal and vertical positions, must be set to 0; the start size from the [RSZ_SRC_HSZ](#) register must be set to the input image width minus 1, and the [RSZ_SRC_VSZ](#) register must be set to the input image height minus 1. These are common settings for both resize engines inside the RESIZER. After setting, more flexibility is present through [RZx_i_VPS](#) and [RZx_i_HPS](#) registers for vertical and horizontal positioning, respectively, of the input/output (where x = A or B, i = I or O).

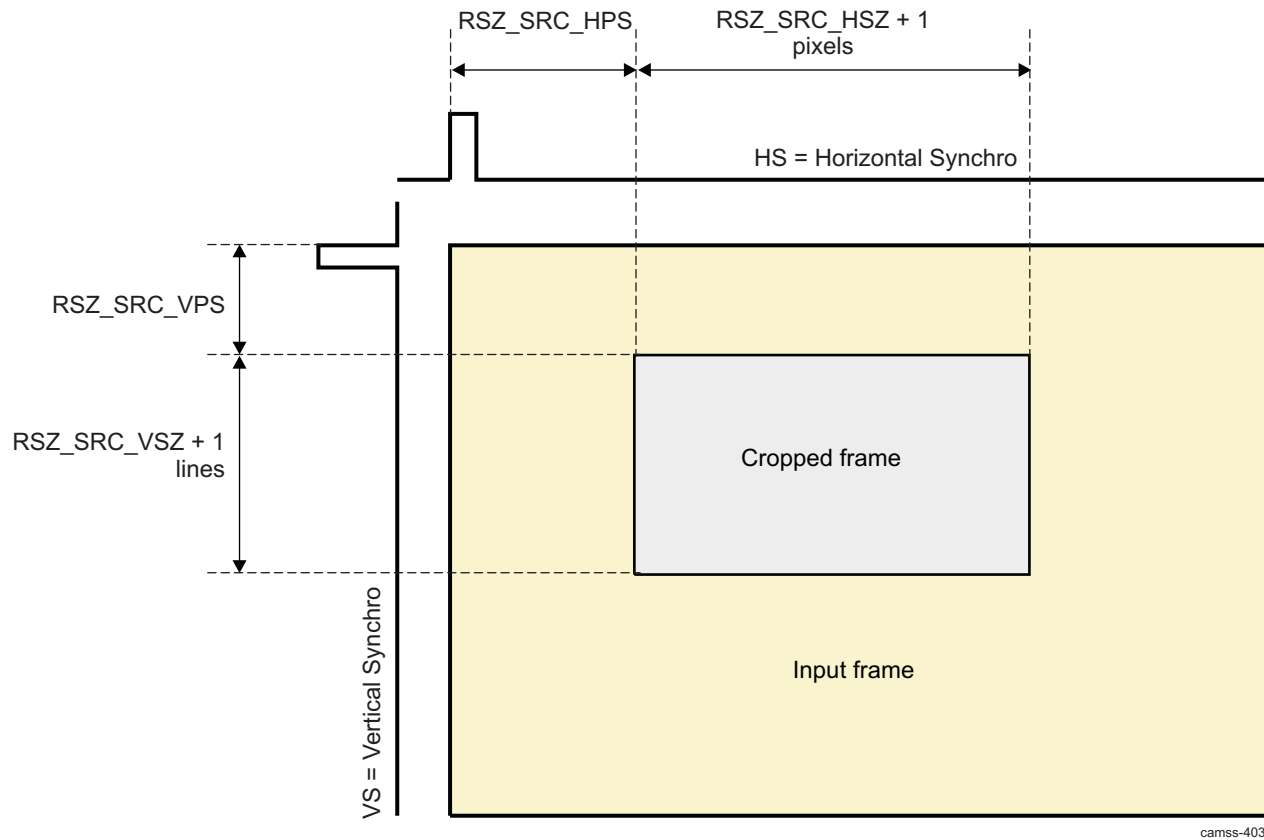

NOTE: After the RSZ second-level cropping (defined by the [RZA_I_VPS](#) and the [RZB_I_VPS](#) register settings), the height of the image frame must be two lines or larger. A one-line image is not allowed.

Depending on the input data format, different constraints apply to the registers that set the cropping parameters:

- For YUV4:2:2 format, the vertical start positions of the cropped frame can be even or odd. However, the horizontal start position must be even: the reason is to always start with the same pattern: Cb_{2n}, Y_{2n}, Cr_{2n}, Y_{2n+1},... For the same reason, the horizontal size of the cropped frame ([RSZ_SRC_HSZ](#) + 1) must be an even number. Finally, the vertical size of the cropped frame can be odd or even.
- For RAW format, the vertical start position of the cropped frame can be even or odd. The vertical size can be even or odd. The horizontal resolution must be even.

These features and constraints are common for both resizer engines inside the resizer module. Figure 8-163 shows the input data cropping.

Figure 8-163. ISS ISP RSZ Input Data Cropping

camss-403

8.3.3.5.5.3 ISS ISP RSZ Averager

8.3.3.5.5.3.1 ISS ISP RSZ Use Cases

The two RSZ engines can have independent averager settings:

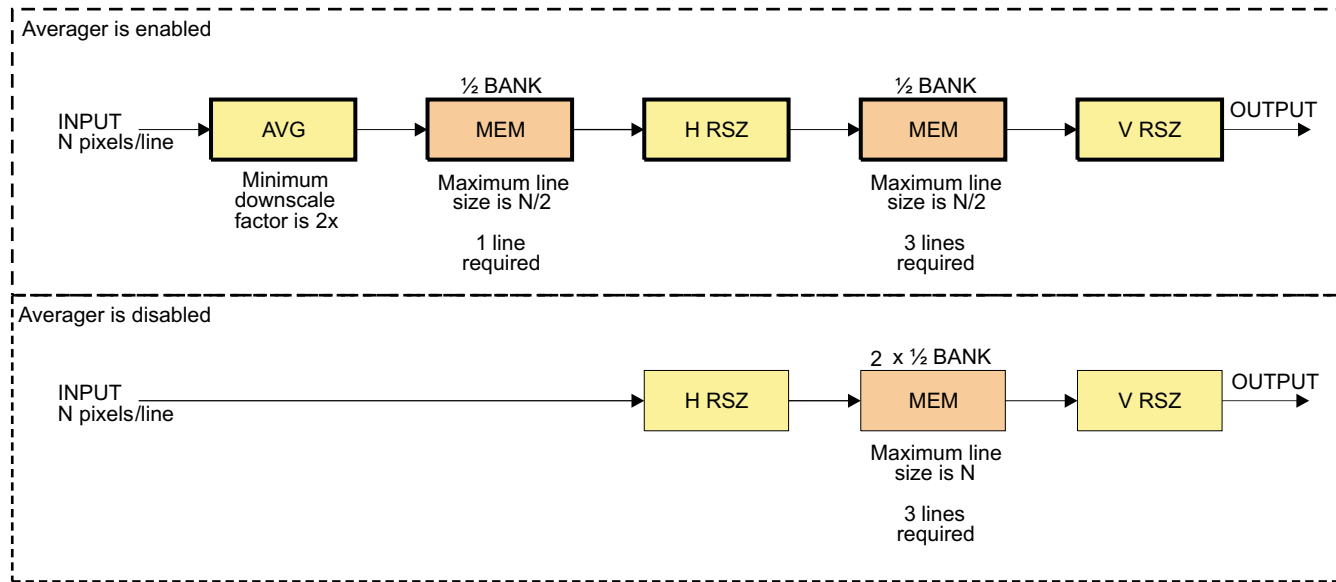

- Both resizers can use it.
- One resizer can bypass it and the other can use it.
- Both resizers can bypass it.

8.3.3.5.5.3.2 ISS ISP RSZ Memory Utilization

Vertical averaging requires memory to perform pixel data accumulation. It shares the vertical memory lines that are used for vertical filtering: this is the reason why the vertical memory lines are organized as two banks of half lines.

- The averagers output lines that are at most half the size of the input image in one memory bank.
- The horizontal resizers write their output data in the second memory banks.

Figure 8-164 shows the use of memory when the averager is enabled or disabled.

Figure 8-164. ISS ISP RSZ Averager Memory Utilization

camss-407

8.3.3.5.3.3 ISS ISP RSZ Border Conditions

Figure 8-165 shows the averager behavior for border conditions. If the input image is not big enough, border duplication must occur.

Figure 8-165. ISS ISP RSZ Averager Border Conditions

camss-408

Downscaling is enabled from the RZi_DWN_EN register. Moreover, the vertical averaging size is set by the RZA_DWN_AV[3:5] V bit field. The actual downscale ratio is given by $1/2^{(RZA_DWN_AV[3:5] V + 1)}$. The range is from 1/2 to 1/256 in power of two. The horizontal averaging size is set by the RZA_DWN_AV[0:2] H bit field. The actual downscale ratio is given by $1/2^{(RZA_DWN_AV[0:2] H + 1)}$. The equations are the same for RSZ-B. The range goes from 1/2 to 1/256 in power of 2.

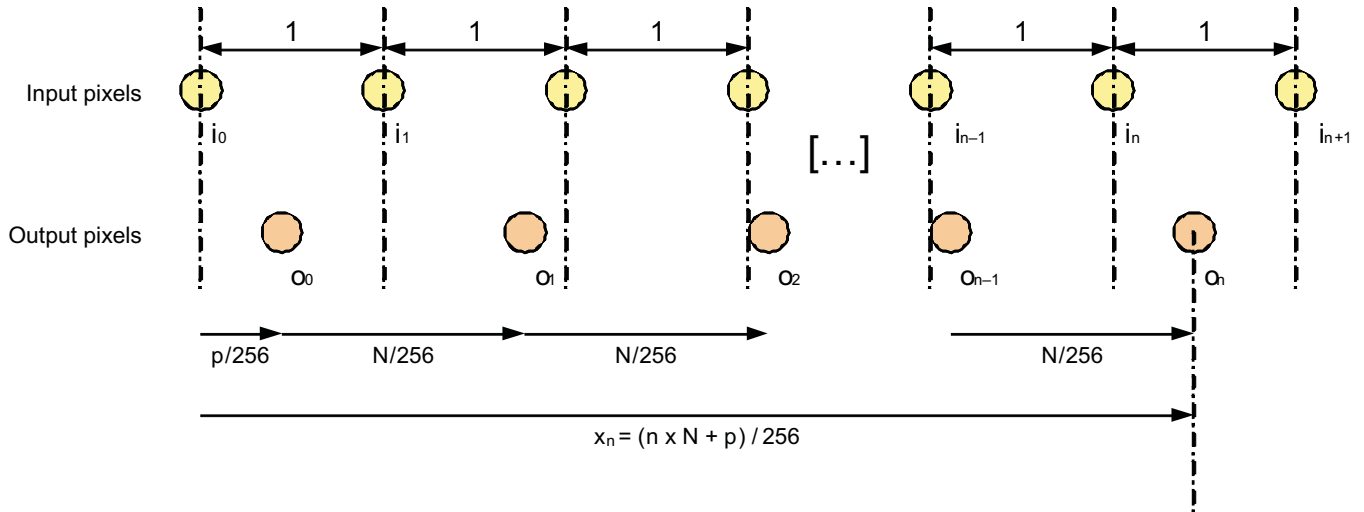

8.3.3.5.5.4 ISS ISP RSZ Interpolation

Figure 8-166 shows the basic interpolation method used in the RESIZER module. The following assumptions are made:

- The distance between each input pixel is 1.
- The magnification ration is given by $256/N$ and $p/256$ is the initial phase of the output data.

The output pixels are also evenly spaced. The distance between each output pixel is given by $N/256$. In the example in Figure 8-166, N is greater than 256. The position of the n^{th} output pixel is given by $(n \times N + p) / 256$.

Figure 8-166. ISS ISP RSZ Basic Interpolation Method

camss-682

Assuming the intensity of input pixels is i_0, i_1, i_2 , etc. and the resized (output) pixels are o_0, o_1, o_2 , etc., the n^{th} output pixel (o_n) is determined using the nearest 4 input pixels as follows:

$$o_n = h(1+d) \times i_1 + h(d) \times i_m + h(d-1) \times i_{m+1} + h(d-2) \times i_{m+2}$$

In the previous equation $h(x)$ is the interpolation main function. The RESIZER module supports linear and bicubic convolution interpolation functions.

Figure 8-167 shows the interpolation principle at the n^{th} output pixel (o_n) at position x_n . Furthermore, the m and d parameters are as follows:

$$m = \text{floor}((n \times N + p) / 256) \text{ and } d = ((n \times N + p) / 256) - m$$

Figure 8-167. ISS ISP RSZ Interpolation Filtering

camss-683

For each resizer (RSZ-A or RSZ-B), and for chrominance and luminance, the interpolation method for vertical interpolation can be a 2-tap linear interpolation or a 4-tap cubic convolution (default) method. The choice is made in RZi_V_TYP[0] Y for luminance and RZi_V_TYP[1] C for chrominance, where $i = A$ or B and is the resizer number. It is similar for horizontal interpolation from RZi_H_TYP[0] Y for luminance and RZi_H_TYP[1] C for chrominance, where $i = A$ or B and is the resizer number.

8.3.3.5.5.4.1 ISS ISP RSZ Liner Interpolation Input Data

Before data interpolation, a low pass filtering (LPF) operation is required on the input data. The following equation gives the LPF function. The equation is evaluated at pixel position d_i , but neighbor pixels d_{i-1} and d_{i+1} are required. The gain value g is set up by the register RZi_V_LPF and RZi_H_LPF. Different gains are possible horizontally and vertically as well as for Luma and Chroma.

$$LPF_g(d_{i-1}, d_i, d_{i+1}) = d_i + g \times (d_{i-1} - 2d_{i+1} + d_{i+2})/128$$

8.3.3.5.5.4.1.1 ISS ISP RSZ Cubic Convolution Mode

The input data is not modified in bicubic mode. Basically, the input is equal to the output.

8.3.3.5.5.4.1.2 ISS ISP RSZ Phase Settings

The initial value for the phase value for vertical resizing is set by the RZi_V_PHS_Y for luminance and RZi_V_PHS_C for chrominance. These values are in the U14Q8 fractional format (values in the range [0 – 63.996]). When YUV4:2:2 data are output, the phase value for Luma and Chroma must be aligned; that is, $RZi_V_PHS_Y = RZi_V_PHS_C$.

The following constraint equation applies: $|RZi_V_PHS_Y - RZx_V_PHS_C| \leq RZi_V_DIF$. This constraint means that at most the distance between the initial phases for luminance and chrominance is not expected to exceed the distance between two Luma pixels. The absolute value is used; therefore, the initial Luma phase can be greater than the initial Chroma phase or vice versa. As a reminder, the distance between two output pixels for Luma is given by RZi_V_DIF.

The initial value for the phase value for horizontal resizing is set by the RZi_H_PHS bit field. The RZi_H_PHS_ADJ register enables adjusting the horizontal phase for the Luma component when averaging is enabled (the averager disrupts the relative sampling point between luminance and chrominance when YUV4:2:2 cosited data is input). The relative phase between Luma and Chroma is different before and after the horizontal averager. The vertical phase is not affected by the averager. [Figure 8-168](#) shows the effect of the averager on the phases. RZi_H_PHS_ADJ is expected to be equal to zero if the averager is disabled.

Figure 8-168. ISS ISP RSZ-A/RSZ-B Phase Averager Effect

Input Chroma is co-sited: relative input I/O phases btw Y and UV are different, correction is needed.

Input Chroma is centered: relative input I/O phases btw Y and UV are identical, no correction is needed.

camss-685

8.3.3.5.5 ISS ISP RSZ Data Saturator

After vertical rescaling and before color conversion, the output data is saturated (clipped) to programmable values that are given by the following registers:

- [RSZ_YUV_Y_MIN](#)
- [RSZ_YUV_Y_MAX](#)
- [RSZ_YUV_C_MIN](#)
- [RSZ_YUV_C_MAX](#)

The maximum Y value is set up with the [RSZ_YUV_Y_MAX](#) register. If the Input Y value is greater than the MAX value, it is clipped to MAX.

The minimum Y value is set up with the [RSZ_YUV_Y_MIN](#) register. If the Input Y value is smaller than the MIN value, it is clipped to MIN.

The maximum Cb/Cr value is set up with the [RSZ_YUV_C_MAX](#) register. If the Input Cb/Cr value is greater than the MAX value, it is clipped to MAX.

The minimum Cb/Cr value is set up with the [RSZ_YUV_C_MIN](#) register. If the Input Cb/Cr value is smaller than the MIN value, it is clipped to MIN.

8.3.3.5.5.6 ISS ISP RSZ Color Convertor

As mentioned previously, the resizer can support RAW, YUV4:2:0, and YUV4:2:2 formats. The resizer engines can also support RGB output: RGB5:6:5 and ARGB32.

The RGB5:6:5 data is 16 bits wide and consists of 5 bits for red, 6 bits for green, and 5 bits for blue.

The following table shows the way RGB5:6:5 is stored to memory. This data format is compatible with the display controller. Only the little-endian memory representation is supported.

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|----|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| R1 | | | | | G1 | | | | | | B1 | | | | | R0 | | | | G0 | | | B0 | | | | | | | | |

The ARGB32 data is 32 bits wide and consists of 8 bits for alpha, 8 bits for red, 8 bits for green, and 8 bits for blue. The alpha value is global and is set for the entire frame; registers control the alpha value: the RZx_RGB_BLD register controls the alpha values of resizer A and resizer B.

The following table shows the way ARGB32 is stored to memory. This data format is compatible with the display controller. This representation is endianness invariant: it is the same for little endian and big endian.

| | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | | |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|---|---|---|---|---|---|---|---|---|---|
| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| A | | | | | | | | R | | | | | | | | G | | | | | | | | B | | | | | | | |

The RGB output is enabled by setting the RZx_RGB_EN[0] RGB_EN bit to 1.

The RGB format is set by the RZx_RGB_TYP[0] TYP bit (0 for ARGB32 format and 1 for RGB5:6:5).

To handle the horizontal border conditions, the leftmost Chroma sample or the right-most Chroma sample is duplicated on the left or the right.

Software must make it possible to remove 2 pixels on the left and/or right to take care of the issues that Chroma duplication introduces on the borders. The RZx_RGB_TYP[1] MSK0 and RZx_RGB_TYP[2] MSK1 bits control this feature.

Figure 8-169. ISS ISP RSZ Chroma Position and Upsampling

8.3.3.5.5.7 ISS ISP RSZ Output Interface

The output interface receives the data generated by the two resizer engines and generates the addresses and the port requests to the BL module.

- The port 1 interface is dedicated to the RSZ-A module. If the RSZ module is set up in pass-through mode, then the data is output on the port 1 interface. This interface can transfer RAW, YUV4:2:2, YUV4:2:0 and RGB data
- The port 2 interface is dedicated to the RSZ-B module. This interface can transfer RAW, YUV4:2:2, YUV4:2:0 and RGB data.

The YUV4:2:0 data format is handled differently from the other formats because the output data are written at two different memory locations: luminance in one buffer and chrominance in a second buffer. For all other formats the data are written in the same buffer.

Each data format must be stored in memory in a dedicated manner, which is summarized in [Table 8-323](#).

Table 8-323. ISS ISP RSZ Output Interface: Data Formats

| Output Format | Bytes per Pixel | Output Buffers per Image | Interface Supporting the Data Format |
|---------------|-----------------|--------------------------|--------------------------------------|
| RAW | 2 | 1 | MTC port 1 |
| YUV4:2:2 | 2 average | 1 | MTC port 1 port 2 |
| YUV4:2:0 | 1.5 average | 2 | MTC port 1 port 2 |
| RGB16 | 2 | 1 | MTC port 1 port 2 |
| ARGB32 | 4 | 1 | MTC port 1 port 2 |

8.3.3.5.5.7.1 ISS ISP RSZ Circular Buffer

[Figure 8-170](#) shows the parameters that are required to set up the circular buffers. As mentioned previously, there can be up to four circular buffers in case the two resizer engines are outputting YUV4:2:0 data.

The circular buffer management requires the following parameters (REZ-A or RSZ-B A or B ,chrominance or luminance Y or C, low or high part of the address, L or H. Sets the base address of the circular buffer):

- Baseline address (BAD, in registers, where x is the resizer A or B, i is Y or C.
- Start address (SAD, in RZx_SDR_i_SAD_j registers)
- Start pointer (PTR_S, in RZx_SDR_i_PTR_S registers)
- End pointer (PTR_E, in RZx_SDR_i_PTR_E registers)
- Line offset (OFT, in RZx_SDR_i_OFT registers)

| Circular Buffer Parameter | Register (for RSZ-A and RSZ-B) | Description |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Baseline address | RZA_SDR_Y_BAD_H RZA_SDR_Y_BAD_L RZA_SDR_C_BAD_H RZA_SDR_C_BAD_L RZB_SDR_Y_BAD_H RZB_SDR_Y_BAD_L RZB_SDR_C_BAD_H RZB_SDR_C_BAD_L | Sets the base address of the circular buffer |
| Start address | RZA_SDR_Y_SAD_H RZA_SDR_Y_SAD_L RZA_SDR_C_SAD_H RZA_SDR_C_SAD_L RZB_SDR_Y_SAD_H RZB_SDR_Y_SAD_L RZB_SDR_C_SAD_H RZB_SDR_C_SAD_L | Sets the start address of the circular buffer. The first data output is written to this address. If the first line of a frame must be written at the beginning of the circular buffer memory, then SAD = BAD and PTR_S = 0. |
| Start pointer | RZA_SDR_Y_PTR_S RZA_SDR_C_PTR_S RZB_SDR_Y_PTR_S RZB_SDR_C_PTR_S | Sets the initial value of the circular buffer internal counter. It must be set up as $PTR_S = (SAD - BAD)/OFT$. PTR_S is expressed in the number of lines. |
| End pointer | RZA_SDR_Y_PTR_E RZA_SDR_C_PTR_E RZB_SDR_Y_PTR_E RZB_SDR_C_PTR_E | Sets the size of the circular buffer. PTR_E is expressed in the number of lines. The circular buffer can contain up to PTR_E lines. |
| Line offset | RZA_SDR_Y_OFT RZA_SDR_C_OFT RZB_SDR_Y_OFT RZB_SDR_C_OFT | This is the offset expressed in bytes between two lines in the circular buffer. Here: Line 0 = SAD, Line 1 = SAD + 1 x OFT, Line 2 = SAD + 2 x OFT, etc. OFT does not necessarily correspond to the size of a line in a frame; it can be bigger. |

More generally, the following equations hold:

- $SAD = BAD + (PTR_S \times OFT)$ and $PTR_S < PTR_E$

Interrupts can be triggered every time a certain number of lines are written to the circular buffer. There are independent settings for each resizer and for each possible output of each resizer.

Figure 8-170. ISS ISP RSZ and Circular Buffer Settings

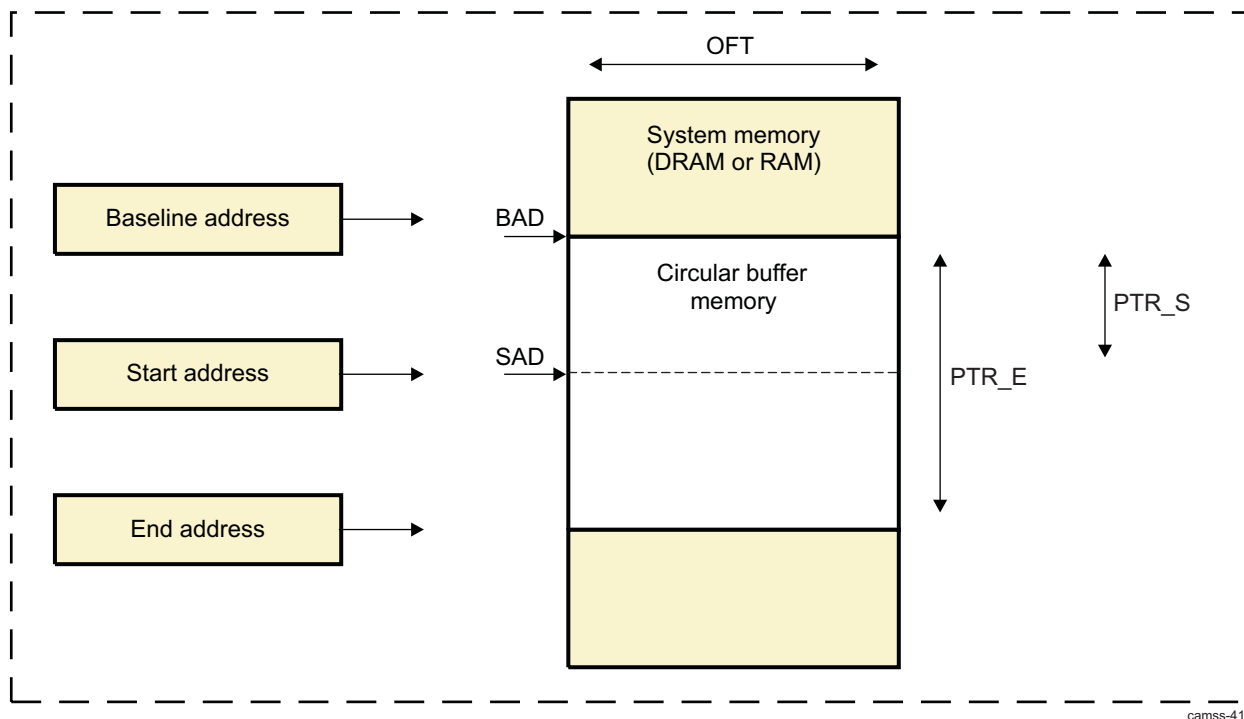

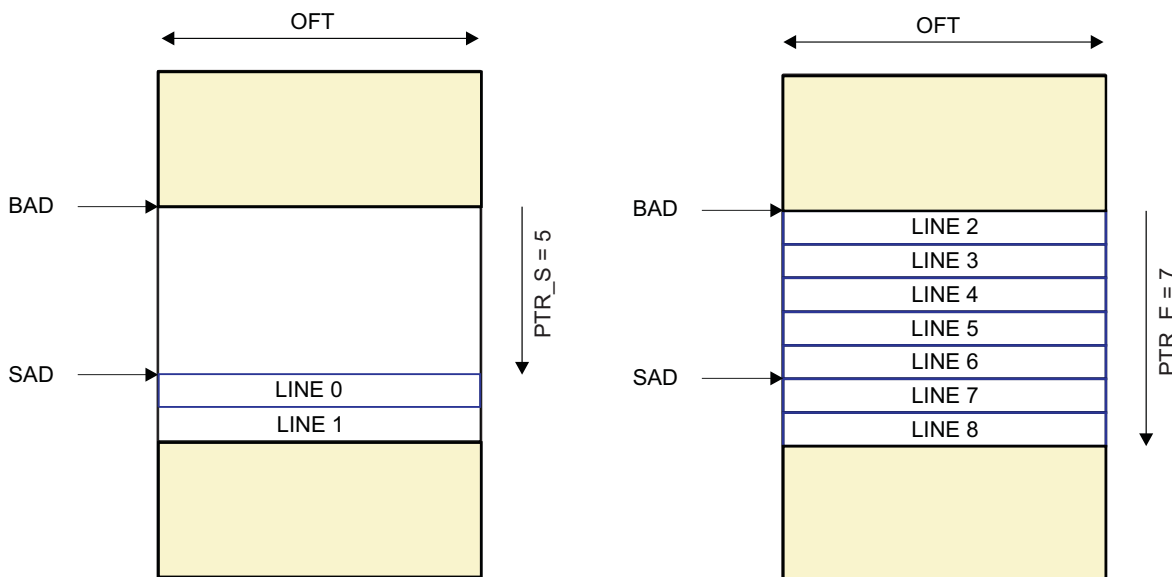

Figure 8-171 shows how the data are stored in the circular buffer over time when vertical flip is disabled. In this example, PTR_S = 5 and PTR_E = 7. There can be up to PTR_E = 7 lines in the circular buffer.

Figure 8-171. ISS ISP RSZ and Circular Buffer Settings – Example 1

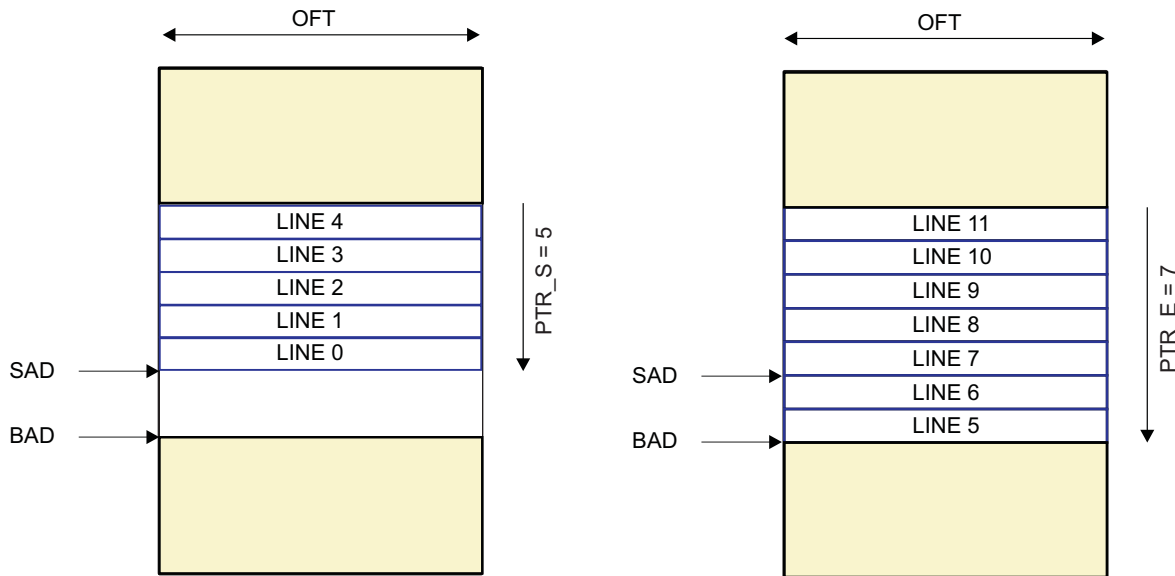

Vertical flip enabled:

1. Start from SAD.
2. Output PTR_E – PTR_S lines.
3. Wrap to BAD.
4. Output PTR_E lines and continue wrapping to BAD.

camss-412

Figure 8-172 shows how the data are stored in the circular buffer over time when vertical flip is enabled. In this example, PTR_S = 5 and PTR_E = 7. There can be up to PTR_E = 7 lines in the circular buffer.

Figure 8-172. ISS ISP RSZ and Circular Buffer Settings – Example 2

Vertical flip enabled:

1. Start from SAD.
2. Output PTR_E – PTR_S lines.
3. Wrap to BAD.
4. Output PTR_E lines and continue wrapping to BAD.

camss-413

8.3.3.6 ISS ISP H3A Functional Description

8.3.3.6.1 ISS ISP H3A Overview

The H3A module supports the control loops for autofocus, auto white balance, and auto exposure by collecting metrics about the imaging/video data. The metrics are used to adjust parameters for processing the imaging/video data. There are two main blocks in the H3A module:

- Autofocus (AF) engine:
 - The AF submodule extracts and filters the red, green, and blue data from input image data and provides the accumulation or peaks of the data in a specified region. The specified region is a 2D block of data referred to as a paxel. The AF engine supports the following features:
 - Peak mode in a paxel
 - Accumulation of the maximum focus value (FV) of each line in a paxel
 - Accumulation mode in a paxel
 - Accumulation of horizontal and vertical focus value in a paxel
 - Up to 12 paxels in the horizontal direction and up to 12 paxels in the vertical direction with vertical focus
 - Up to 36 paxels in the horizontal direction and up to 128 paxels in the vertical direction with horizontal focus only
 - Programmable width and height for the paxel/window
 - Programmable red, green, and blue position within a 2 x 2 matrix
 - Separate horizontal start for paxel and filtering

- Programmable vertical and horizontal line increments within a paxel
- Horizontal FV uses parallel infinite impulse response (IIR) filters configured in a dual-biquad configuration with individual coefficients (two filters with 11 coefficients each). The filters are intended to compute the sharpness/peaks in the frame to focus on.
- Vertical FV uses a 5-tap FIR filter with 8-bit coefficients. With horizontal steps each paxel has up to 32 columns to be maintained for vertical FV calculation.
- Auto exposure and auto white balance (AE/AWB) engine:

The AE/AWB engine accumulates values and checks for saturated values in a subsampling of the video data. In the case of the AE/AWB, the 2D block of data is referred to as a window. Thus, other than having different names, paxels and windows are essentially the same. However, the numbers, dimensions, and starting positions of AF paxels and AE/AWB windows are programmable separately. AE/AWB supports the following features:

 - Accumulate clipped pixels along with all nonsaturated pixels in each window per color
 - Accumulate the sum of squared pixels in each window per color
 - Minimum and maximum pixel values in each window per color
 - Supports for up to 36 horizontal windows with sum + { sum_sq or min+max} output
 - Support for up to 56 horizontal windows with sum output
 - Support for up to 128 vertical windows
 - Programmable width and height for the windows. All windows in the frame are the same size.
 - Separate vertical start coordinate and height for a black row of paxels that is different than the remaining color paxels
 - Programmable horizontal sampling points in a window
 - Programmable vertical sampling points in a window
- Maximum pixel throughput of 200 MPix/s
- Double-buffer for paxel/window accumulation
- H3A data path is 10 bits.
- Maximum input size is 3008 pixels.

[Figure 8-173](#) shows the H3A module connections to other submodules of the ISP.

Figure 8-173. ISS ISP H3A High-Level Diagram

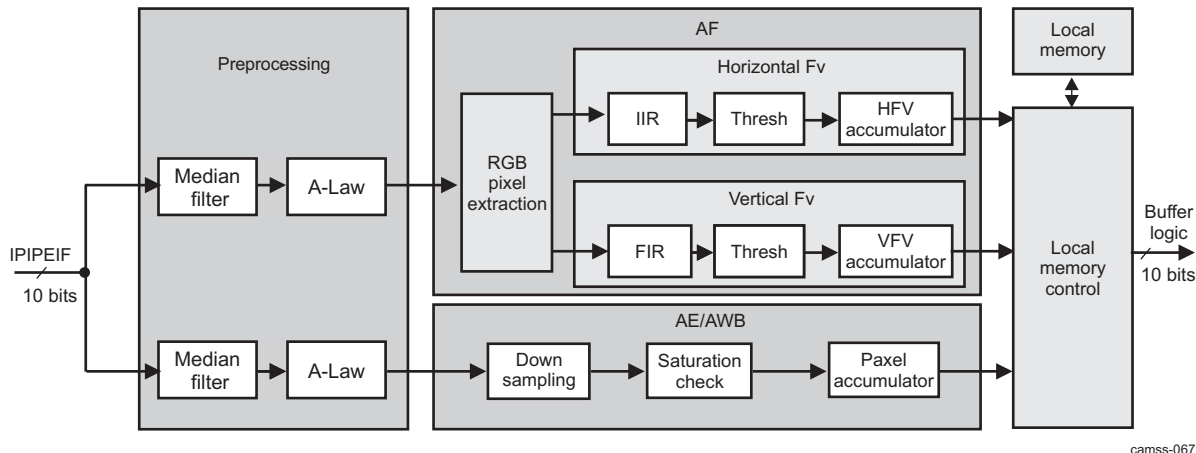

8.3.3.6.2 ISS ISP H3A Top-Level Block Diagram

The block diagram in [Figure 8-174](#) shows the process of the AF and AE/AWB data paths through the H3A module.

The data flow before H3A is:

1. Data comes from the VP (VP) or BL.
2. The data is processed by the ISIF.
3. The data is processed by the IPIPEIF.
4. The data is 10 bits from the IPIPEIF at H3A input.

Figure 8-174. ISS ISP H3A Top-Level Block Diagram

8.3.3.6.3 ISS ISP H3A Line Framing Logic

In certain cases the number of clock cycles between HD pulses is greater than the line buffer included in the H3A. To solve this problem a framing module was added before the line buffer. The framing module uses the [H3A_LINE_START](#) register to find the position of the first pixel to place into the line buffer. All other registers reference this point as the 0 pixel for their start positions. The line size is 3008 pixels. After 3008 clock cycles the framing logic disables the line buffer and waits until the next HD. If the next HD comes before 3008 clock cycles, then the active region ends immediately and the counter waits for the [H3A_LINE_START](#) register count to be reached again. For the vertical position the [H3A_LINE_START\[31:16\]](#) SLV bit field can be used to determine where the start point of the frame is relative to the rising edge of VD. This logic allows for an active frame to cross VD boundaries and remain in the same frame.

Figure 8-175. ISS ISP H3A Frame Format Settings

NOTE: (Frame width on VP) - ([H3A_LINE_START\[15:0\]](#) LINE_START) must be less than or equal to 3008, because the H3A memory lines are limited to 3008 pixels.

8.3.3.6.4 ISS ISP H3A Optional Preprocessing

The input to the H3A module is 10-bit RAW data from the IPIPEIF. A 10-bit to 8-bit A-Law compression step can be enabled and disabled separately for the AF engine (the [H3A_PCR\[1\]](#) AF_ALAW_EN bit) and the AE/AWB engine (the [H3A_PCR\[17\]](#) AEW_ALAW_EN bit). A-Law compression offers added protection against overflowing the accumulators.

If the A-Law table is enabled, the output is 10 bits, with the upper two bits filled with 0.

For the AF process, a horizontal median filter can be enabled and disabled (the [H3A_PCR\[2\]](#) AF_MED_EN bit) before A-Law compression. This filter is useful for reducing temperature-induced noise. The horizontal median filter calculates the absolute difference between the current pixel (i) and pixel ($i - 2$), and between the current pixel (i) and pixel ($i + 2$). If the absolute difference exceeds a threshold, and the sign of the differences is the same, the average of pixel ($i - 2$) and pixel ($i + 2$) replaces pixel (i). The threshold of the horizontal median filter can be set in the [H3A_PCR\[10:3\]](#) MED_TH bit field.

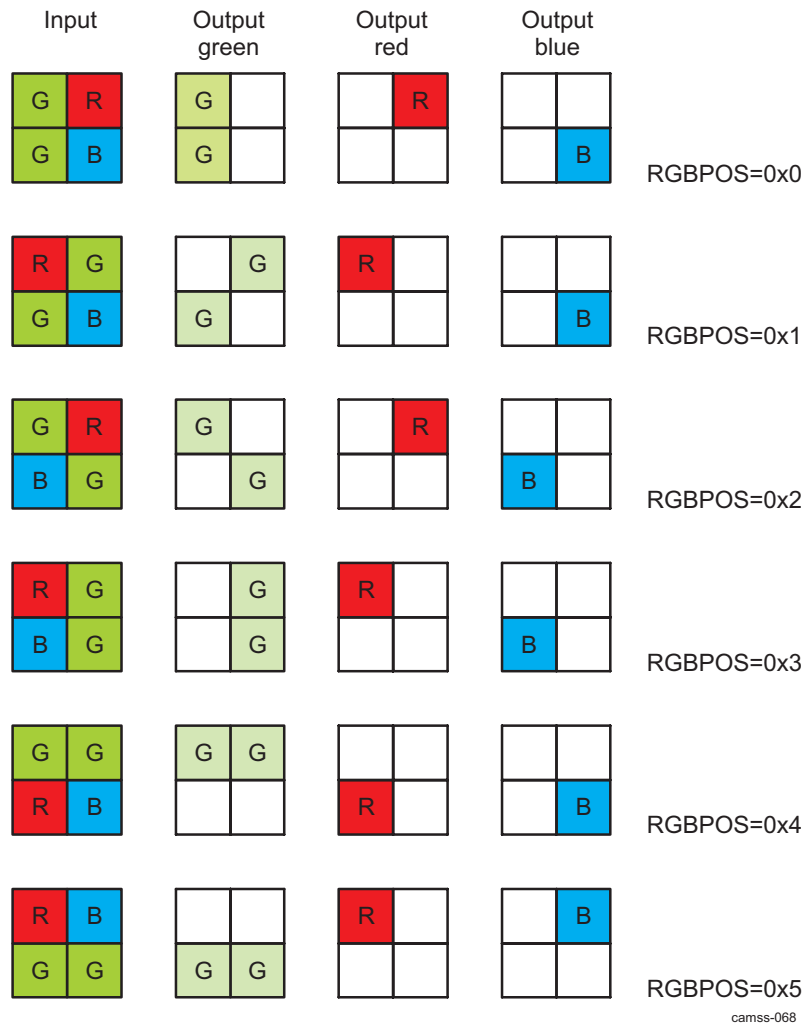

8.3.3.6.5 ISS ISP H3A Autofocus Engine

The AF engine works by extracting each green (Gr or Gb) pixel from the video stream and subtracts a fixed offset of 128 or 512 (depending on whether A-Law is enabled or disabled) from the pixel value. The offset value is then passed through an IIR filter and the absolute value of the filter output is the focus value (FV). Both FV and FV^2 are produced. The FV and FV^2 values can be accumulated or the maximum for each line/column can be accumulated. The following sections describe this process in more detail.

8.3.3.6.5.1 ISS ISP H3A Poxel Extraction

From the poxel starting coordinate (the [H3A_AFPAXSTART\[27:16\]](#) PAXSH and [H3A_AFPAXSTART\[11:0\]](#) PAXSV bit fields) specifies the starting point of the poxel grid, with respect to first pixel of the input image frame.

The poxel starting coordinate also indicates which color pixels are extracted if VF is enabled (that is, if [H3A_PCR\[20\]](#) AF_VF_EN = 1). Normally, either Gr or Gb is used for AF, but it is not important to the hardware whether it is red, green, or blue. If VF is not enabled, then the red, green, and blue pixel extraction is controlled by the [H3A_PCR \[13:11\]](#) RGBPOS bit field to extract the correct colors from the input stream. [Figure 8-177](#) shows the available options for this bit field. The red and blue pixel positions are interchangeable. For each 2×2 grid, the green pixels are summed to create a single value. Because of this, the amplitude of the green output contains 2 pixels, while the red and blue outputs each contain 1 pixel.

Figure 8-176. ISS ISP H3A Red, Green, and Blue Pixel Extraction Examples

camss-068

Each paxel is $H3A_AFPAX1[23:16]$ PAXW \times $H3A_AFPAX1[7:0]$ PAXH (width \times height) pixels. Inside each paxel, horizontal FV can skip lines, operating on one every $H3A_AFPAX2[16:13]$ AFINCV lines. Vertical FV can skip columns, operating on one every $H3A_AFPAX2[20:17]$ AFINCH columns. Up to 32 columns are supported for each paxel. If floor (PAXW/AFINCH) \geq 32, only the first 32 designated columns are operated on. Because PAXW, PAXH, AFINCV, and AFINCH are all even numbers, AF always operates on the same green color, Gr or Gb. IIR filters for the horizontal FVs start operation at column $H3A_AFIIRSH[11:0]$ IIRSH.

Figure 8-177. ISS ISP H3A Horizontal/Vertical FV Poxel Configuration

camss-071

NOTE: $(H3A_AFPAXSTART[27:16] PAXSH) + (H3A_AFPAX2[5:0] PAXHC) \times (H3A_AFPAX1[23:16] PAXW) \leq [(Frame\ width\ on\ VP) - (H3A_LINE_START[15:0] LINE_START)] \leq 3008$

Table 8-324 lists the register fields that configure the size and number of pixels.

Table 8-324. ISS ISP H3A Poxel Register Field Descriptions

| Register Field | Bit Width | Description |
|-----------------------------|-----------|--------------------------------------|
| H3A_AFPAX1[23:16] PAXW | 8 | Poxel width (in pixels) |
| H3A_AFPAX1[7:0] PAXH | 8 | Poxel height (in lines) |
| H3A_AFPAX2[5:0] PAXHC | 6 | Poxel count for horizontal direction |
| H3A_AFPAX2[12:6] PAXVC | 7 | Poxel count for vertical direction |
| H3A_AFPAX2[16:13] AFINCV | 4 | Line increments in a poxel |
| H3A_AFPAX2[20:17] AFINCH | 4 | Column increments in a poxel |
| H3A_AFPAXSTART[27:16] PAXSH | 12 | Poxel start position H |
| H3A_AFPAXSTART[11:0] PAXSV | 12 | Poxel start position V |
| H3A_AFIIRSH[11:0] IIRSH | 12 | IIR filter start position |

The H3A AF engine also has an option for an advanced or normal stats collection mode. When 0xCA00 is written to the H3A_ADVANCED[31:15] ID bit field, then H3A_ADVANCED[0] AF_MODE can be used to toggle between normal and advanced AF stats collection mode. When the advanced AF stats collection mode is enabled, the ZEROS section of the AF poxel packet is filled with the sum of the maximum FVs, regardless of the color, from HFV_1 and HFV_2.

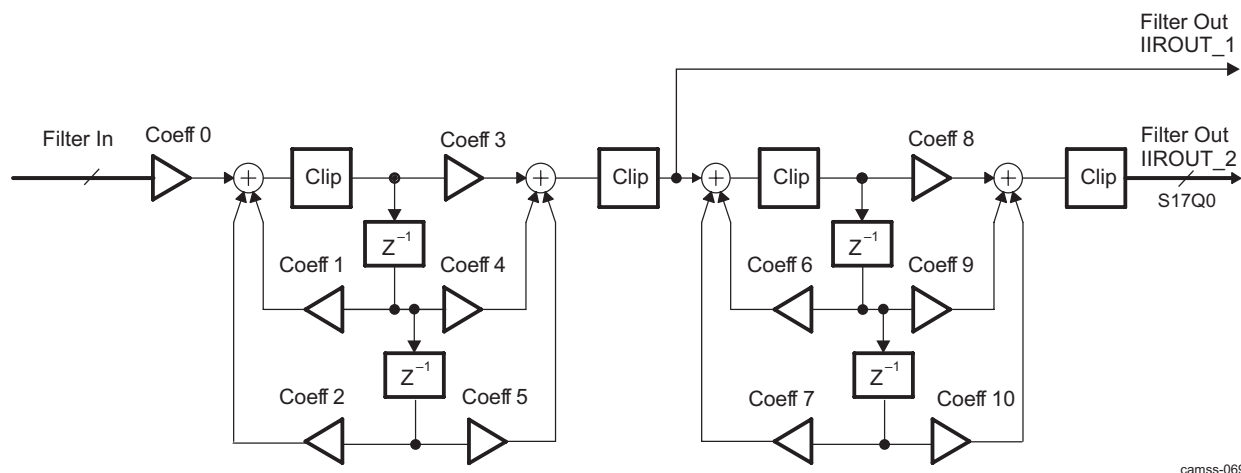

8.3.3.6.5.2 ISS ISP H3A Horizontal FV Calculator

The FV calculator takes the unsigned red/green/blue extracted data and subtracts 128 or 512 (depending on whether A-Law is enabled) to place the data in the range [-128:127] or [-512:511].

After removing the offset, the data is sent through two parallel IIR filters configured in a dual-biquad configuration. Each filter uses a unique set of 11 programmable coefficients. Each coefficient is 12-bits-wide with 6 bits of decimal, S12Q6 ([H3A_AFcoef010](#) to [H3A_AFcoef0010](#) for SET0, and [H3A_AFcoef110](#) to [H3A_AFcoef1010](#) for SET1). The filter-shift registers are cleared on each horizontal line at the position set by the register IIR horizontal start register (the [H3A_AFIIRSH](#) [11:0] IIRSH bit field). The absolute values of the output (16-bits-wide with 4 bits of decimal, U16Q4) of both filters are then sent to the AF accumulator module. Signed clipping is performed during the FV calculation. If the input value is m bits (signed) and the required output value is n bits, clipping transforms the input to between -2^1 and 2^1 . Values lower than -2^1 are set to -2^1 , and values higher than 2^1 are set to 2^1 .

Figure 8-178 shows the IIR filter model.

Figure 8-178. ISS ISP H3A IIR Filter Model

camss-069

8.3.3.6.5.3 ISS ISP H3A HFV Accumulator

The horizontal focus value (HFV) accumulator takes the output of the horizontal IIR filter and accumulates values for each paxel. The size and number of paxels is configurable by registers.

Table 8-324 lists the register fields that configure the size and number of paxels:

- In peak mode ([H3A_PCR](#)[14] FVMODE = 0x1), the maximum value is accumulated.
- In sum mode ([H3A_PCR](#)[14] FVMODE = 0x0), all HFV_n are accumulated in a paxel.

The following equations detail the calculation for:

- Sum of pixel values used in HFV: The pixel values that are used for filtering and accumulation of HFV are also accumulated in this sum of pixel values.
- HFV_n (HFV_{n_peak} for peak mode or HFV_{n_sum} for sum mode)
- HFV_count_n
- HFV_sq_n (HFV_sq_{n_peak} for peak mode or HFV_sq_{n_sum} for sum mode)

$n = 1$ or 2 for IIR1 and IIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```
for (k=0; k < PAXH) // Loop on paxel rows
{
    rowpeak_n = 0;

    for (l=0; l<PAXW; l++) // Loop on values within a row
    {
        aIIRout_n = ABS(IIRout_n);
        if (aIIRout_n >= threshold_n)
        {
            hfval = aIIRout_n - threshold_n;
            HFV_count_n++;
        }
    }
}
```

```

else hfval = 0;
if (hfval > rowpeak_n)
{
rowpeak_n = HFV_n;
}
HFV_n_sum += hfval;
HFV_sq_n_sum += (hfval* hfval + RNDADD) >> RNDSHIFT;
} // Finished looping on values in a row
HFV_n_peak += rowpeak_n;
HFV_sq_n_peak += (rowpeak_n * rowpeak_n + RNDADD) >> RNDSHIFT;
}

```

- threshold_n is [H3A_HVF_THR\[15:0\]](#) HTHR1 and [H3A_HVF_THR\[31:16\]](#) HTHR2, respectively.
- IIRout_n is the IIRout_1 and IIRout_2 outputs, respectively.
- HFV_count_n and HFV_sq_n are not sent to the DMA interface if VF is disabled.
- RNDADD and RNDSHIFT depend on whether input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.
- If VF is enabled, only the green color channel values are output to the DMA interface.
- In sum mode:
 - HFV_n = HFV_n_sum
 - HFV_sq_n = HFV_sq_n_sum
- In peak mode:
 - HFV_n = HFV_n_peak
 - HFV_sq_n = HFV_sq_n_peak

8.3.3.6.5.4 ISS ISP H3A VFV Calculator

The VFV calculator takes the unsigned extracted data through two FIR filters, each with a set of five coefficients (VCOEF1_x, where x = 0..4, in the [H3A_VFV_CFG1](#) and [H3A_VFV_CFG2](#) registers for FIR 1, and VCOEF2_x, where x = 0..4, in [H3A_VFV_CFG3](#) and [H3A_VFV_CFG4](#) registers). Each coefficient is 8 bits wide with 4 bits of decimal (S8Q4). The filter outcome is downshifted by 4 bits and taken absolute value to produce a 16-bit unsigned value. This is then sent to threshold [H3A_VFV_CFG2\[31:16\]](#) VTHR1 for FIR 1, and [H3A_VFV_CFG4\[31:16\]](#) VTHR2 for FIR 2, and square logic to produce VFV_n and VFV_sq_n.

8.3.3.6.5.5 ISS ISP H3A VFV Accumulator

The VFV accumulator takes the output of the vertical FIR filters and accumulates values for each paxel. The size and number of paxels is configurable by registers.

[Table 8-324](#) lists the register fields that configure the size and number of paxels.

The following equations detail the calculation for:

- VFV_n
- VFV_count_n
- VFV_sq_n

n = 1 or 2 for FIR1 and FIR2, respectively.

For each paxel, these six values are available for each R, G, and B component.

```

FIR_coef_n = [VCOEFn_0, VCOEFn_1, VCOEFn_2, VCOEFn_3, VCOEFn_4]; /* coefficient values in S8.4
format */
aFIRout_n = (ABS(inner_product(extracted_G, FIR_coef_n)) + 8) >> 4;

if (aFIRout_n >= threshold_n)
{
VFV_n = aFIRout_n - threshold_n
VFV_count_n++;
}

```

```
else VFV_n = 0;
```

```
VFV_sq_n = (VFV_n * VFV_n + RNDADD) >> RNDSHIFT;
```

- threshold_n is [H3A_VFV_CFG2\[31:16\]](#) VTHR1 and [H3A_VFV_CFG4\[31:16\]](#) VTHR2, respectively.
- FIRout_n is the FIRout_1 and FIRout_2 outputs, respectively.
- RNDADD and RNDSHIFT depend on whether the input pixels are 8-bit or 10-bit, and achieves rounding. This is automatically performed by the module.

8.3.3.6.6 ISS ISP H3A AE/AWB Engine

The AE/AWB engine starts by dividing the frames into windows, and then subsamples each window into 2×2 blocks. For each subsampled 2×2 block, each pixel is accumulated. Also, each pixel is compared to a limit set in a register. If any pixels in a 2×2 block are greater than or equal to the limit, the block is not counted in the unsaturated block counter. Pixels greater than the limit are replaced by the limit, and the value of the pixel is accumulated.

The AE/AWB module has three output format modes, which are set through the [H3A_AEWCFG\[9:8\]](#) AEFMT bit field:

- Sum of square mode: [H3A_AEWCFG\[9:8\]](#) AEFMT = 0x0
- Min/max mode: [H3A_AEWCFG\[9:8\]](#) AEFMT = 0x1
- Sum-only mode: [H3A_AEWCFG\[9:8\]](#) AEFMT = 0x2

8.3.3.6.6.1 ISS ISP H3A Sub_sampler

The subsampler partitions the frame into windows using the size, count, and starting location parameters shown on the left in [Figure 8-175](#). Each window is further sampled down to a set of 2×2 blocks. The horizontal and vertical distances between the start of blocks within a window is programmable using the parameters shown on the right in [Figure 8-175](#).

Figure 8-179. ISS ISP H3A AE/AWB Window Configurations

[Table 8-325](#) lists the register fields that configure the window and block sizes, counts, and starting positions.

Table 8-325. ISS ISP H3A AE/AWB Window Register Field Descriptions

| Register Field | Bit Width | Description |
|-----------------------------------------|-----------|---------------------------------------|
| H3A_AEWWIN1[20:13] WINW | 7 | Window width (in pixels) |
| H3A_AEWWIN1[31:24] WINH | 7 | Window height (in lines) |
| H3A_AEWWIN1[5:0] WINHC | 6 | Window count for horizontal direction |

Table 8-325. ISS ISP H3A AE/AWB Window Register Field Descriptions (continued)

| Register Field | Bit Width | Description |
|-----------------------------|-----------|----------------------------------------|
| H3A_AEWWIN1[12:6] WINVC | 7 | Window count for vertical direction |
| H3A_AEWINSTART[11:0] WINSH | 12 | Window start position H |
| H3A_AEWINSTART[27:16] WINSV | 12 | Window start position V |
| H3A_AEWSUBWIN[3:0] AEWINCH | 4 | Horizontal distance between subsamples |
| H3A_AEWSUBWIN[11:8] AEWINCV | 4 | Vertical distance between subsamples |

8.3.3.6.2 ISS ISP H3A Additional Black Row of AE/AWB Windows

In addition to the 128 rows of windows, the AE/AWB module provides support for an additional row of windows for black data. This data may be useful in determining the DC offset noise of the rest of the data. The black row of windows can be before or after the regular rows of windows. The vertical start line for the black row of windows is specified in the H3A_AEWINBLK[27:16] WINSV bit field, and the height is specified in the H3A_AEWINBLK[6:0] WINH bit field. The horizontal starting pixel and horizontal width of the black row of windows are the same as for the regular rows of windows.

Figure 8-180 shows a black row of windows before rows of windows.

Figure 8-180. ISS ISP H3A Black Row of Windows Before Regular Rows of Windows

Table 8-326. ISS ISP H3A AE/AWB Window with Additional Black Row Register Field Descriptions

| Register Field | Bit Width | Description |
|-----------------------------|-----------|------------------------------------------------|
| H3A_AEWWIN1[20:13] WINW | 7 | Window width (in pixels) |
| H3A_AEWWIN1[31:24] WINH | 7 | Window height (in lines) |
| H3A_AEWWIN1[5:0] WINHC | 6 | Window count for horizontal direction |
| H3A_AEWWIN1[12:6] WINVC | 7 | Window count for vertical direction |
| H3A_AEWINSTART[11:0] WINSH | 12 | Window start position H |
| H3A_AEWINSTART[27:16] WINSV | 12 | Window start position V |
| H3A_AEWSUBWIN[3:0] AEWINCH | 4 | Horizontal distance between subsamples |
| H3A_AEWSUBWIN[11:8] AEWINCV | 4 | Vertical distance between subsamples |
| H3A_AEWINBLK[27:16] WINSV | 12 | Window start position H for single black line |
| H3A_AEWINBLK[6:0] WINH | 7 | Window height (in lines) for single black line |

8.3.3.6.6.3 ISS ISP H3A Saturation Check

The saturation check module compares the data from the subsampler to the value programmed in the [H3A_PCR](#) [31:22] AVE2LMT bit field. This value is the maximum clipping value. If all 4 pixels in the 2 × 2 block are less than the AVE2LMT value, the value of the unsaturated block counter is incremented. There is one unsaturated block counter per window. The unsaturated block counters are later written to memory.

8.3.3.6.6.4 ISS ISP H3A AE/AWB Accumulators

The output from the saturation check module and the subsampler module are separately accumulated for each pixel in every 2 × 2 pixel block for each window. Therefore, there are eight accumulators per window (one accumulator for each pixel in a 2 × 2 pixel block, times two sets of accumulators: clipped/saturated data and presaturated data). Each of the 4 pixels in the 2 × 2 pixel grid is associated with a color (R, Gr, B, Gb); however, the output of these accumulators is referenced by position in the grid, not color.

The accumulators are 16 bits wide, and the accumulated data is 10 bits wide. Therefore, when a window contains more than 64 pixels of the same color, an overflow risk exists. This risk can be reduced by enabling the A-Law conversion in the preprocessing stage. See [Section 8.3.3.6.4](#) for details.

The AE/AWB module has a shift value for the accumulation of pixel values that is set in the [H3A_AEWCFG](#)[3:0] SUMSHFT bit field.

8.3.3.6.7 ISS ISP H3A DMA Interface

The DMA interface module takes the data from the AF engine and AE/AWB engine and builds packets to be sent out to the memory through the BL module.

The data interface has separate start pointers for the AF and AE/AWB engines.

- The starting address for the AF engine is the [H3A_AFBUFST](#)[31:5] AFBUFST bit field.
- The starting address for the AE/AWB engine is the [H3A_AEWBUFST](#)[31:5] AEWBUFST bit field.

The DMA interface module continuously loops through this data as it builds the packets. To optimize the transfer sizes, the DMA interface sends out an AF or AE transfer for each row of pixels or windows. This requires that each horizontal row of pixels or windows starts and ends on a 32-byte boundary. If a horizontal row of pixels or windows ends on a non-32 byte boundary, the hardware packs zeroes. The counts for the AEW that occur every eight windows is sent in the row with the 8th consecutive window.

[Table 8-327](#) lists the packet formats for AF with vertical AF disabled.

Table 8-327. ISS ISP H3A AF Packet Format With Vertical AF Disabled

| Buffer Start Address (Byte Address) | 31 | 16 | 15 | 0 |

8.3.3.6.8 ISS ISP H3A Events and Status Checking

The AF and AEW engines generate an interrupt event at the end of processing each frame. However, these two interrupts are internally tied together so that only one H3A interrupt signal is generated. If the AF engine and AEW engine do not process the same frame concurrently, this should not be an issue. However, if they do run concurrently, one of two outcomes may occur:

- The H3A interrupt may seem to trigger only once for each frame. This can happen when the processing for the AF and AEW engines finishes at or near the same time. The interrupt service routine does not have enough time to clear the interrupt flag for the first interrupt before the second interrupt occurs.
- The H3A interrupt may trigger twice for each frame. This can happen when the AF engine or the AEW engine finishes processing the frame much earlier than the other engine. In this case, the interrupt service routine does have enough time to clear the interrupt flag for the first interrupt by the time the second interrupt occurs.

The outcome depends on the difference in location of the last paxel/window in the frame (determines when processing is finished), the frequency of the relative clocks in the system, the occurrence and triggering of other interrupts in the system, and the latencies of the context switching and interrupt service routine execution.

The [H3A_PCR\[15\]](#) BUSYAF and/or [H3A_PCR\[18\]](#) BUSYAEAWB status bits are set when the start of frame occurs (if the [H3A_PCR\[0\]](#) AF_EN and/or [H3A_PCR\[16\]](#) AEW_EN bits are 1 at that time). They are automatically reset to 0 at the end of processing a frame. The [H3A_PCR\[15\]](#) BUSYAF and/or [H3A_PCR\[18\]](#) BUSYAEAWB status bits may be polled to determine the end of frame status.

8.3.3.7 ISS ISP ISIF Functional Description

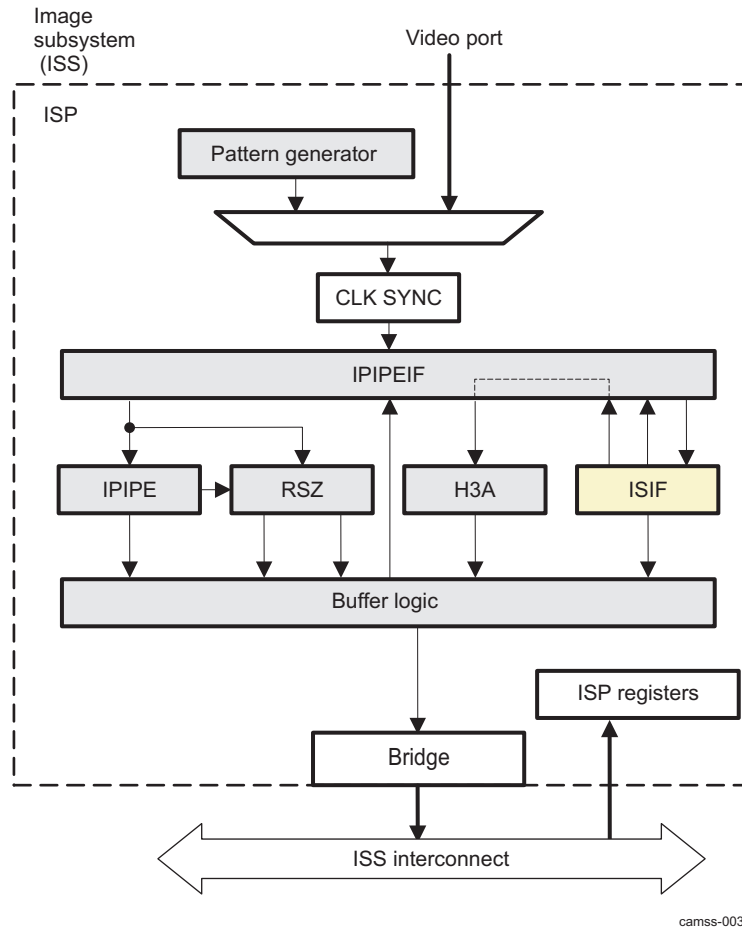

8.3.3.7.1 ISS ISP ISIF Overview

The image sensor interface (ISIF) module receives RAW or YUV4:2:2 data from the IPIPEIF module. The module outputs data back to the IPIPEIF module and can also output data to memory through the BL (Buffer Logic) module. The ISIF module can process the incoming data and supports the following functions:

- Maximum supported image size is 32,768 X 32,768
- Supports up to 16-bit analog front end
- Sensor Data linearization
- Supports Bayer and Foveon® input data format (RGB and CMYG color support)
- Supports VGA read out mode
- Supports various image data format
- Color space conversion
- Digital clamp with Horizontal/Vertical offset drift compensation
- Vertical line defect correction
- Programmable 2D-matrix LSC
- Gain and offset control
- Programmable H/V culling pattern
- Max pixel rate clock of 200 MPix/s on the VP interface.
- 10-to-8 bits A-Law compression table inside
- 12-bit pack supported when written to memory

[Figure 8-182](#) show the ISIF module connections to other submodules of the ISP.

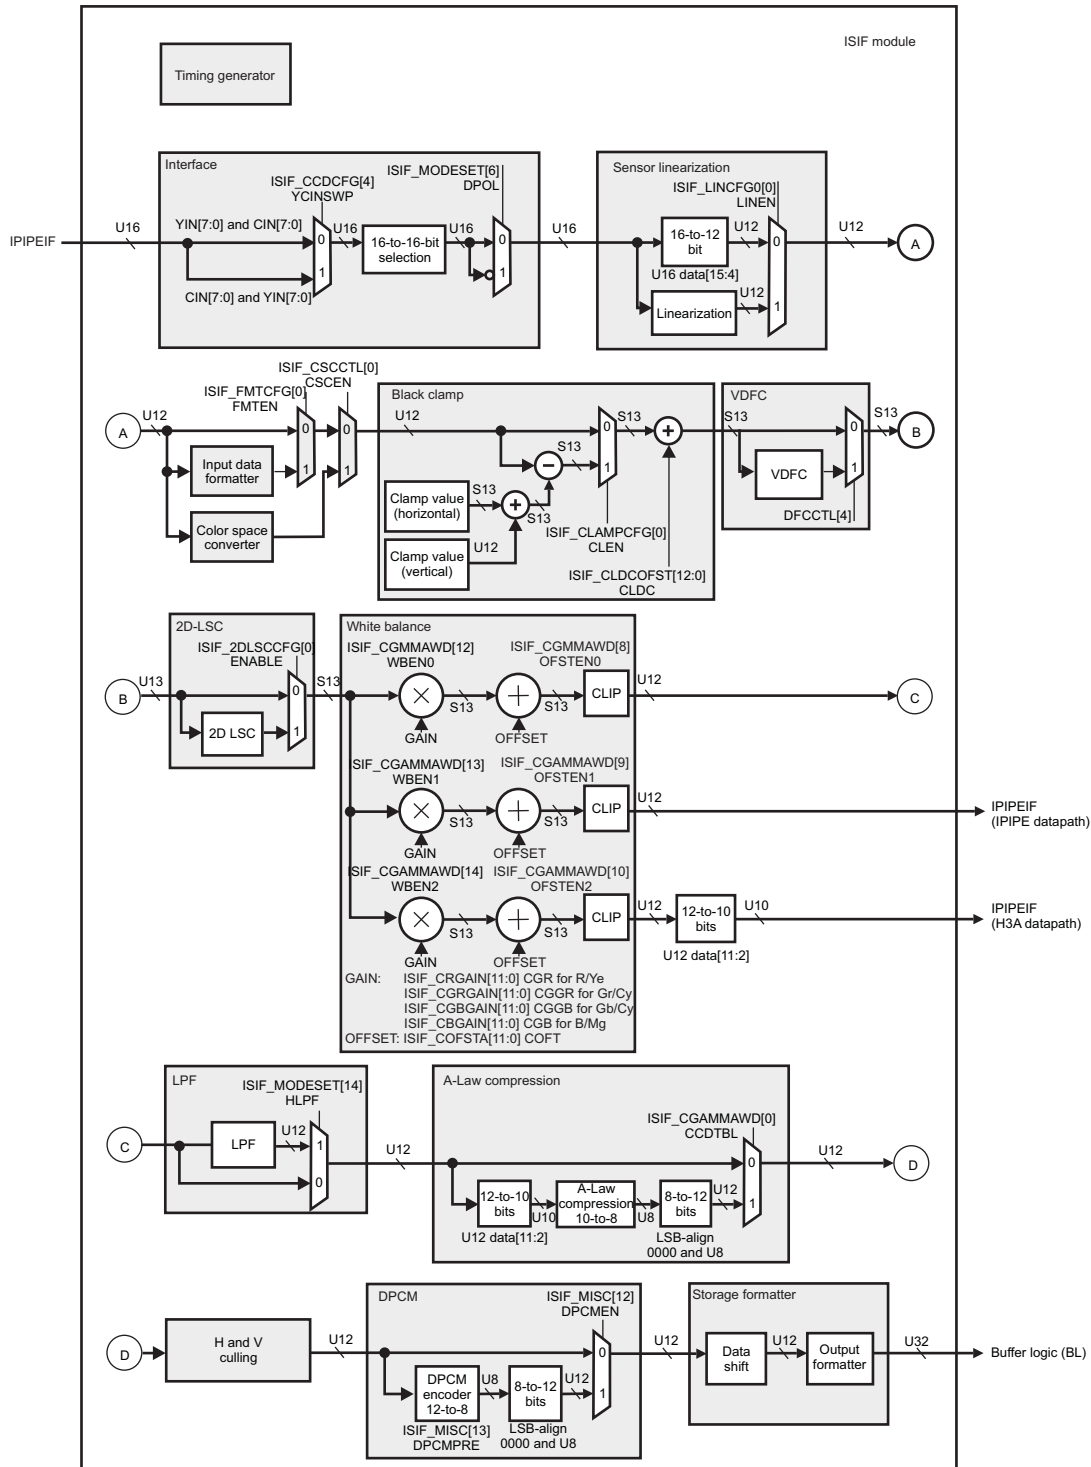

Figure 8-182. ISS ISP ISIF High-Level Diagram

8.3.3.7.2 ISS ISP ISIF Top-Level Block Diagram

Figure 8-183 shows the different blocks of the ISIF module.

Figure 8-183. ISS ISP ISIF Top-Level Block Diagram

camss-074

The following sections describe the blocks in the ISIF module.

8.3.3.7.3 ISS ISP ISIF Input Interface

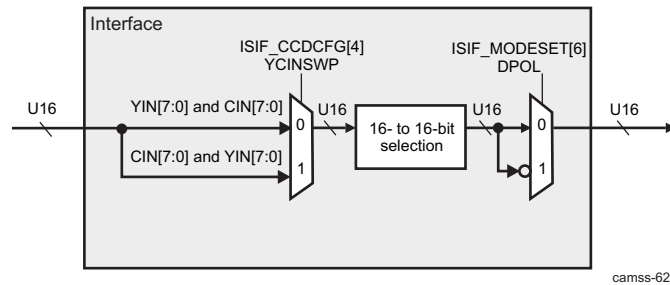

The input interface is a video interface. It comprises the horizontal(HD)I and vertical(VD) synchronization signal, pixel clock (PCLK), and data(DATA). Table 8-332 gives more information about these different signals. The ISIF uses the HD and VD signals provided by the sensor through the VP and IPIPEIF. The pixel clock clocks data into the ISIF at a maximum rate of 200MHz.

Table 8-332. ISS ISP ISIF Input Interface Signals

| Name | I/O | Function |
|------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| VD | I | Vertical sync signal |
| HD | I | Horizontal sync signal |
| PCLK | I | Pixel clock. This signal is the pixel clock used to load image data into the ISIF. The clock controller can configure to trigger on the rising or falling edge of the PCLK signal. |
| DATA | I | Data. The data interface is a 16-bit interface. When the ISIF is configured to write data to SDRAM, the write enable signal allows an external device to control which data is to be written to SDRAM. The data input can be configured from the ISIF_MODESET.INPMOD register where it can be set to RAW, YCbCr (16 bits and 8 bits). The polarity of the data can be changed from the ISIF_MODESET.DPOL as shown in Figure 8-184. |

8.3.3.7.4 ISS ISP ISIF Interface

Figure 8-184. ISS ISP ISIF Interface Block Diagram

The ISIF supports 8- to 16-bit-wide RAW data signals and 8-/16-bit YCbCr signals, as described in Table 8-333. The interface can be set in the three different modes from the ISIF_MODESET[13:12] INPMOD bit field. The ISIF_CCDCFG[11] Y8POS bit selects the y signal positioning whenever YUV4:2:2 is input. Moreover, if CCIR656 input is used the width of selected bit can be set through the ISIF_CCDCFG[5] BT656 bit.

Table 8-333. ISS ISP ISIF Data Input Formats

| ISIF Input Port Name | RAW Data | 16-bit YCbCr | 8-bit YCbCr |
|----------------------|----------|--------------|-------------|
| Y17 | C_DATA15 | Y7 | |
| Y16 | C_DATA14 | Y6 | |
| Y15 | C_DATA13 | Y5 | |
| Y14 | C_DATA12 | Y4 | |
| Y13 | C_DATA11 | Y3 | |
| Y12 | C_DATA10 | Y2 | |
| Y11 | C_DATA9 | Y1 | |
| Y10 | C_DATA8 | Y0 | |

Table 8-333. ISS ISP ISIF Data Input Formats (continued)

| ISIF Input Port Name | RAW Data | 16-bit YCbCr | 8-bit YCbCr |
|----------------------|----------|--------------|-------------|
| CI7 | C_DATA7 | Cb7,Cr7 | Y7,Cb7,Cr7 |
| CI6 | C_DATA6 | Cb6,Cr6 | Y6,Cb6,Cr6 |
| CI5 | C_DATA5 | Cb5,Cr5 | Y5,Cb5,Cr5 |
| CI4 | C_DATA4 | Cb4,Cr4 | Y4,Cb4,Cr4 |
| CI3 | C_DATA3 | Cb3,Cr3 | Y3,Cb3,Cr3 |
| CI2 | C_DATA2 | Cb2,Cr2 | Y2,Cb2,Cr2 |
| CI1 | C_DATA1 | Cb1,Cr1 | Y1,Cb1,Cr1 |
| CI0 | C_DATA0 | Cb0,Cr0 | Y0,Cb0,Cr0 |

Y and C input signals can be swapped through [ISIF_CCDCFG\[4\]](#) YCINSWP bit.

In case of RAW data at ISIF input, a 16- to-16-bit selection can be done: when the number of RAW data lines is less than 16, data can be connected to the upper or lower lines of C_DATA[15:0]. Lines not connected must be tied low. As shown in [Table 8-334](#), the [ISIF_CGAMMAWD\[4:1\]](#) GWDI bit field must be configured correctly so that the MSB of the input is connected to the MSB of the 16-bit data bus in ISIF.

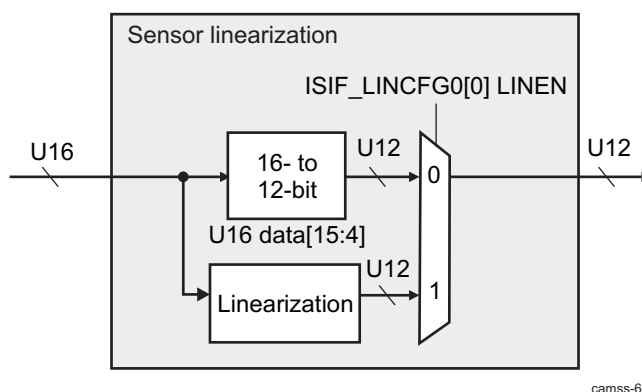

Table 8-334. ISS ISP ISIF Raw Data Connection: Selects MSB Position of Input Data

| ISIF_CGAMMAWD[4:1] GWDI | 16-to-16-bit Selection |
|-----------------------------------------|---------------------------------------|
| 0 | C_DATA [15:0] = C_DATA[15:0] |
| 1 | C_DATA [15:0] = C_DATA[14:0] &0 |
| 2 | C_DATA [15:0] = C_DATA[13:0] &00 |
| 3 | C_DATA [15:0] = C_DATA[12:0] &000 |
| 4 | C_DATA [15:0] = C_DATA[11:0] &0000 |
| 5 | C_DATA [15:0] = C_DATA[10:0] &00000 |
| 6 | C_DATA [15:0] = C_DATA[9:0] &000000 |
| 7 | C_DATA [15:0] = C_DATA[8:0] &0000000 |
| 8 | C_DATA [15:0] = C_DATA[7:0] &00000000 |

The polarity of the input image data can be switched through the [ISIF_MODESET\[6\]](#) DPOL bit.

8.3.3.7.5 ISS ISP ISIF Sensor Linearization

NOTE: For the memory access locations of the sensor linearization table, see [Section 8.3.3.9](#).

Figure 8-185. ISS ISP ISIF Sensor Linearization Block Diagram

The sensor linearization module can correct for the non-linear response of image sensors. A LUT is programmed with an offset value to add to the original pixel value based on the original pixel value.

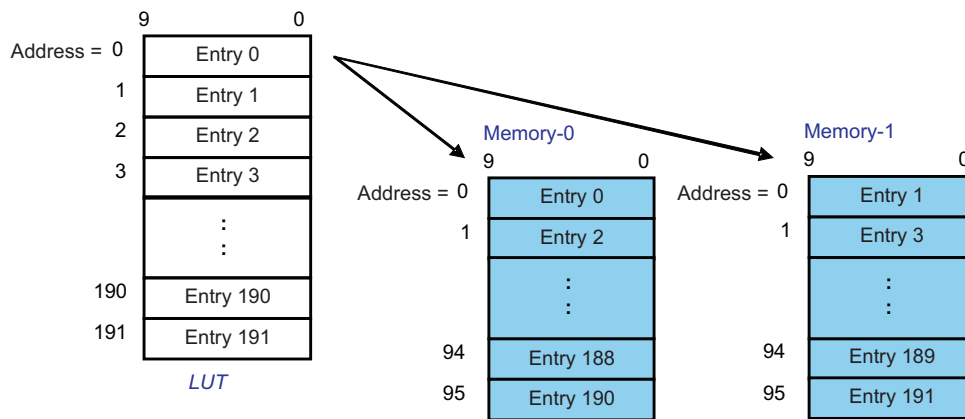

The LUT is a sampling of the linearization correction curve based on calibration of the image sensor. Intermediate values between sampling points are computed using linear interpolation. The entire correction curve is divided into seven regions, as shown in Table 8-335. The regions for the darkest part and the brightest part of the response curve have dense sampling. The linearization mode can be a uniform or a non-uniform sampling and can be set through the ISIF_LINCFG0[1] LINMD bit.

Table 8-335. ISS ISP ISIF Linearization LUT

| Region | Number of Sample Points | LUT Address |
|--------------------------|-------------------------|----------------------|
| table_in[15:11] == 00000 | 32 | table_in[10:6] |
| table_in[15:11] == 00001 | 4 | table_in[10:9] + 32 |
| table_in[15:12] == 0001 | 4 | table_in[11:10] + 36 |
| table_in[15:13] == 001 | 4 | table_in[12:11] + 40 |
| table_in[15:14] == 01 | 4 | table_in[13:12] + 44 |
| table_in[15:14] == 10 | 16 | table_in[13:10] + 48 |
| table_in[15:14] == 01 | 128 | table_in[13:7] + 64 |

The LUT has 192 entries and is split into two 96 ×10-bit memories, as shown in Figure 8-186. The table is mapped in the memory map. The LUT entries are interleaved between memory 0 and memory 1.

Figure 8-186. ISS ISP ISIF Linearization LUT Memories

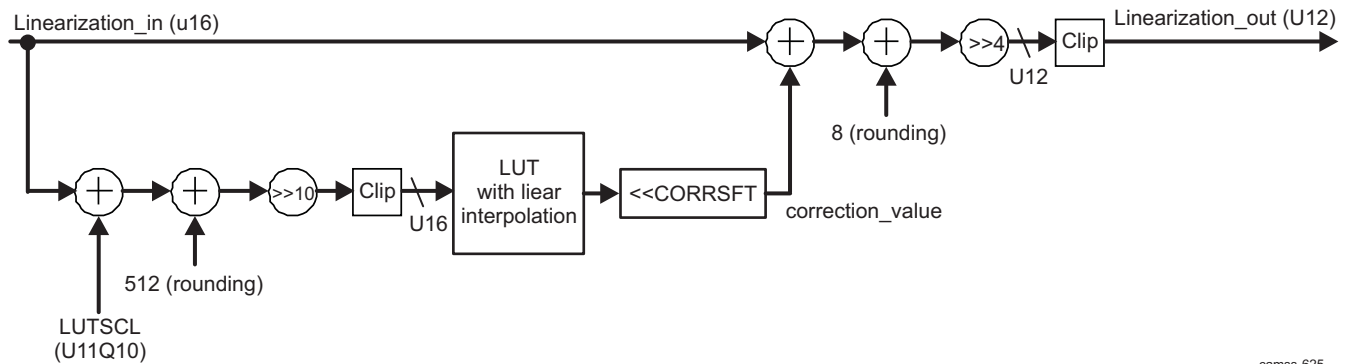

camss-613

Table 8-336. ISS ISP ISIF LUT Memory Region

| Memory Region | Address Range | Description |
|---------------|-----------------|-----------------------------------|
| Memory 0 | 0xC000 – 0xC17F | ISIF linearity compensation LUT 0 |
| Memory 1 | 0xC400 – C57F | ISIF linearity compensation LUT 1 |

A scale factor is applied to the input before lookup through the `ISIF_LINCFG1[10:0]` LUTSCL bit field. The LUT entries are signed 10-bit data (u16). After linear interpolation, the correction value is left-shifted by a programmable amount (the `ISIF_LINCFG0[6:4]` CORRSFT bit field), and then added to the input. This is then converted to unsigned 12-bit by right shift, followed by clipping.

Figure 8-187. ISS ISP ISIF Linearization Block Diagram

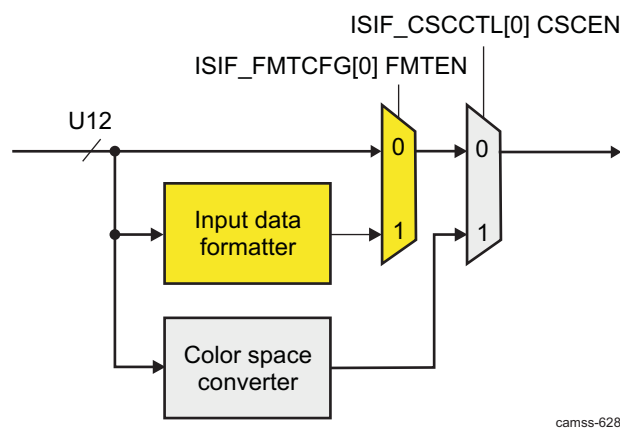

camss-625

To enable the linearization module, set the `ISIF_LINCFG0[0]` LINEN bit to 1.

If the linearization module is disabled (`ISIF_LINCFG0[0]` LINEN = 0x0), a 16- to-12-bit transformation is done, and the upper 12-bits of U16 input are sent to the next block.

8.3.3.7.6 ISS ISP ISIF Input Data Formatter

Figure 8-188. ISS ISP ISIF Input Data Formatter Block Diagram

camss-626

There are two functional blocks: input data formatter and color space converter, which use two 5376×12 -bit memories (corresponds to one line of maximum 5376 pixels with each pixel equal to 12 bits). Only one of the function blocks can be enabled.

The input data formatter block allows the ISIF to handle a wide variety of current and future readout schemes other than Bayer format. Two line memories and a programmable address generator are used to translate those patterns into a standard Bayer pattern (or any other pattern). This allows the back-end processing (noise filters, interpolation, histogram, 3A statistics) to remain unchanged.

The input data formatter block also supports divided input lines. In case an input line is divided into multiple lines and fed to the ISIF, the formatter gathers the divided lines and organizes a single line. Up to four divided lines can be supported.

The input data formatter is enabled through the `ISIF_FMTCFG[0]` FMTEN bit.

The input data formatter can split an input line into 1, 2, 3, or 4 output lines, or can combine the divided 1, 2, 3, or 4 input lines into a single line.

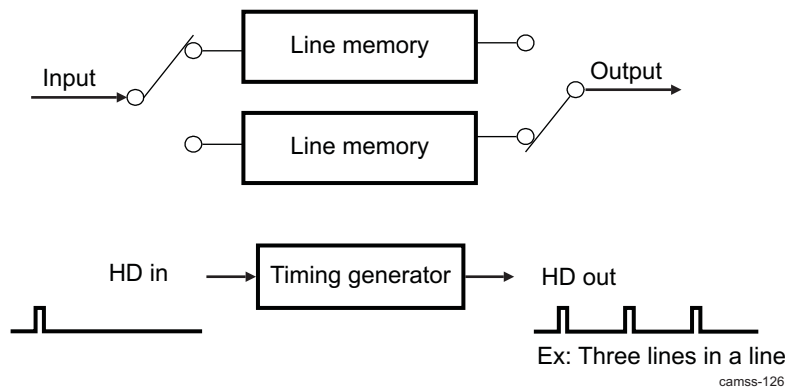

- Set the `ISIF_FMTCFG[1]` FMTCBL bit to 0 for split mode.

- Set the `ISIF_FMTCFG[1]` FMTCBL bit to 1 for combine mode.
- Select the number of lines in the `ISIF_FMTCFG[5:4]` LNUM bit field.

The Input data formatter can work in normal or line alternative mode. The choice is done through the `ISIF_FMTCFG[2]` LNALT bit.

Figure 8-189 shows an example of generating three output lines from an input line with a new, internally generated HD signal.

Figure 8-189. ISS ISP ISIF Splits an Input Line Into Three Output Lines

This HD signal then gates the downstream processing rather than the original sensor HD signal. Descriptions of how to configure the formatter are provided in the following sections.

Because the size of the line memories is 5376 × 12-bits, the following restrictions apply for the data formatter:

- Split mode:
 - The maximum number of pixels that can be supported in an output line if the input line is transformed into 1 output line is 5376
 - The maximum number of pixels that can be supported in an output line if the input line is transformed into 2 output lines is 2688
 - The maximum number of pixels that can be supported in an output line if the input line is transformed into 3 output lines is 1792
 - The maximum number of pixels that can be supported in an output line if the input line is transformed into 4 output lines is 1344
- Combine mode
 - The maximum number of pixels that can be supported in an input line if 1 input line is transformed into an output line is 5376.
 - The maximum number of pixels that can be supported in an input line if 2 input lines are transformed into an output line is 2668.
 - The maximum number of pixels that can be supported in an input line if 3 input lines are transformed into an output line is 1792.
 - The maximum number of pixels that can be supported in an input line if 4 input lines are transformed into an output line is 1344.

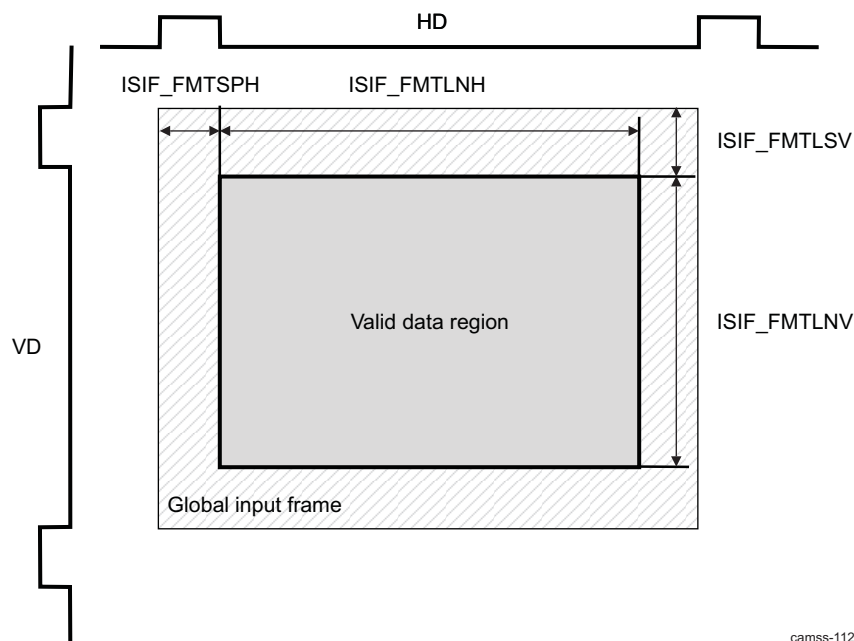

8.3.3.7.6.1 ISS ISP ISIF Formatter Area Settings

As shown in Figure 8-190, the following registers are used to set the formatter area:

- `ISIF_FMTSPH`
- `ISIF_FMTLNH`
- `ISIF_FMTLSV`
- `ISIF_FMTLNV`

Table 8-337 describes these registers. The input line is input to the formatter, and the output line is output from the formatter.

Figure 8-190. ISS ISP ISIF Input Data Formatter Area Settings

camss-112

Table 8-337. ISS ISP ISIF Input Data Formatter Area Setting Registers

| Register | Description |
|-----------------------------|--------------------------------------------------|
| ISIF_FMTSPH | The first valid pixel of an input line |
| ISIF_FMTLNH | Valid length of a input line = FMTLNH + 1 |
| ISIF_FMTLSV | The first valid input line |
| ISIF_FMTLNV | The number of the valid input lines = FMTLNV + 1 |

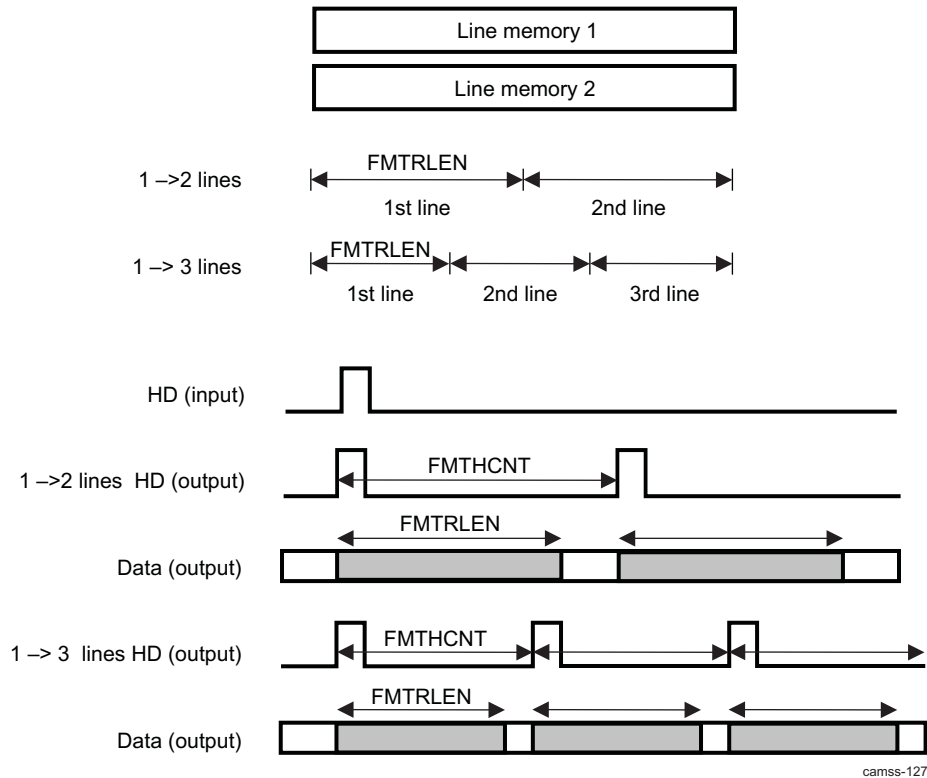

Table 8-338. ISS ISP ISIF Output Data Formatter Area Setting Registers

| Register | Description |
|------------------------------|--------------------------------------------------------------------|
| ISIF_FMTRLEN | The length of an output line |
| ISIF_FMTHCNT | HD interval for output lines |
| ISIF_SPH | The first pixel in an output line to be stored to SDRAM |
| ISIF_LNH | Number of pixels in an output line to be stored to SDRAM = LNH + 1 |
| ISIF_LNV | The number of the output lines to be stored to SDRAM = LNV + 1 |

The number of pixels in an output line must be set to the [ISIF_FMTRLLEN](#) register, and the HD output interval must be set to the [ISIF_FMTHCNT](#) register. It is not necessary to set the [ISIF_FMTHCNT](#) register if multiple input lines are combined into a single line.

[Figure 8-191](#) shows an example of splitting an input line into two or three output lines.

Figure 8-191. ISS ISP ISIF Data Formatter Output Control Example

8.3.3.7.6.2 ISS ISP ISIF Formatter Programming

The data formatter derives its flexibility by supporting up to 16 different addresses and a program that can contain up to 32 entries.

Address pointer

There are 16 address pointer registers ([ISIF_FMTAPTR0](#) to [ISIF_FMTAPTR15](#)), which contain:

- The [ISIF_FMTAPTRx\[14:13\]](#) LINE bit field: 2-bit line number to specify the output line to which it belongs: 0, 1, 2, or 3. It is valid only for the line splitting.
- The [ISIF_FMTAPTRx\[12:0\]](#) INIT bit field: 13-bit initial address for pointer x (where x = 0 to 15)

Each of the address values is auto-incremented or auto-decremented by a programmable value (the [ISIF_FMTCFG\[11:8\]](#) FMTAINC bit field).

Program

There are 32 program entry registers, which contain:

- In the [ISIF_FMTPGMVFO](#) and [ISIF_FMTPGMVF1](#) registers: The PGMxxEN fields (where xx = 00 to 31) set the program entry valid flag.
- In the [ISIF_FMTPGMAPS0](#) to [ISIF_FMTPGMAPS7](#) registers: The PGMxxAPTR fields specify the program xx address pointer (where xx = 00 to 31).
- In the [ISIF_FMTPGMAPU0](#) and [ISIF_FMTPGMAPU1](#) registers: The PGMxxUPDT fields (where xx = 00 to 31) set the program xx address update (increment or decrement).

Because each of the program entries has a valid flag, the formatter can also support images larger than the memory limit (length: 4480) by not choosing some of the entries.

The total program memory of 32 entries is divided into two or four SETs:

- Program memory of 16 entries each for odd and even lines to split the line:
 - SET0 for even input line: Program entry 015
 - SET1 for odd input line: Program entry 1631
- Program memory of eight entries for up to four input lines to combine the lines:
 - SET0 for first input line: Program entry 07
 - SET1 for second input line: Program entry 815
 - SET2 for third input line: Program entry 1623
 - SET3 for fourth input line: Program entry 2431

The number of program entries per SET must be specified by the **ISIF_FMTPLEN** register as follows:

- Number of program entries for SET0: **ISIF_FMTPLEN**[3:0] FMTPLEN0
- Number of program entries for SET1: **ISIF_FMTPLEN**[7:4] FMTPLEN1
- Number of program entries for SET2: **ISIF_FMTPLEN**[10:8] FMTPLEN2
- Number of program entries for SET3: **ISIF_FMTPLEN**[14:12] FMTPLEN3

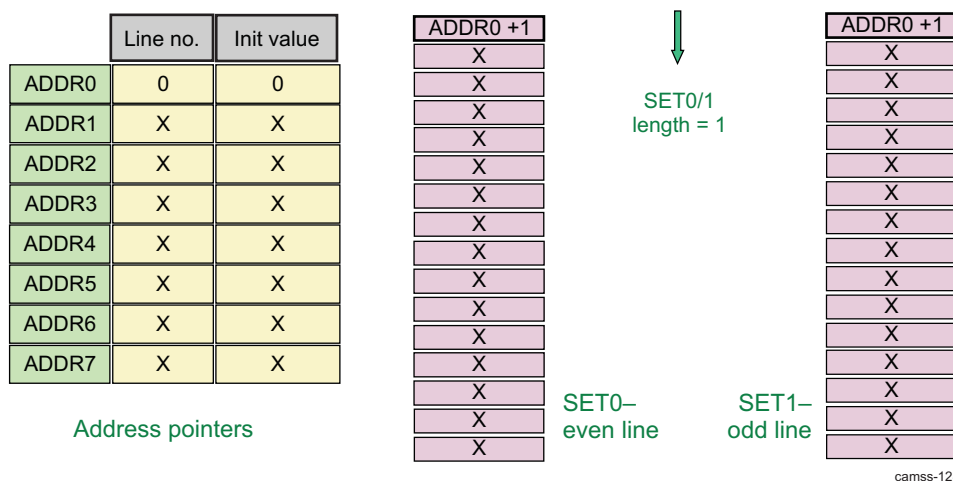

The program entry must be set from the lower registers within a SET. For instance, start from program entry 16 for odd input lines.

The following examples show the programmability of the data formatter:

- Register settings:
 - **ISIF_FMTCFG**[0] FMTEN = 0x1
 - **ISIF_FMTCFG**[1] FMTCBL = 0x0
 - **ISIF_FMTCFG**[11:8] FMTAINC = 0x0 (add or subtract 1)
- 1 input line -> 1 output line

NOTE: ADDR0 is set to an example value. Addresses with no value in the following example are marked with X.

Figure 8-192. ISS ISP ISIF Conventional Read-Out Pattern

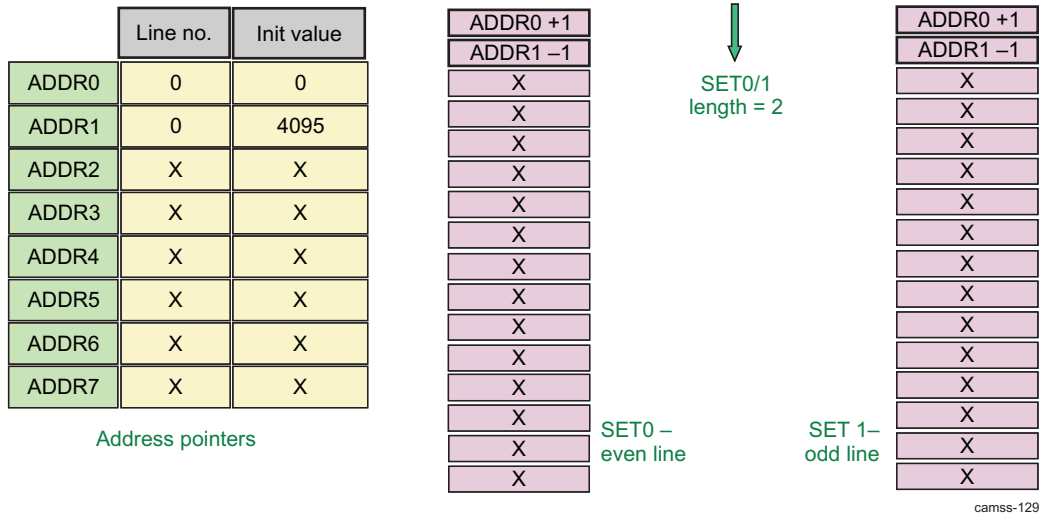

The following examples show the programmability of the data formatter with a 2-tap analog front end (AFE):

- Registers settings:
 - **ISIF_FMTCFG**[0] FMTEN = 0x1

- ISIF_FMTCFG[1] FMTCBL = 0x0
- ISIF_FMTCFG[11:8] FMTAINC = 0x0 (add or subtract 1)
- ISIF_FMTCFG[5:4] LNUM = 0x0
- One input line (4096) -> one output line with left and right read-out
- Input -> First pixel, last pixel, first pixel + 1, last pixel - 1, and so on
- Input -> 0, 4095, 1, 4094, 2, 4093, 3, 4092, ..., 2047 and 2048
- Output -> 0, 1, 2, 3, ..., 4094 and 4095

Figure 8-193. ISS ISP ISIF Conventional Read-Out Pattern With 2-tap AFE

8.3.3.7.6.3 ISS ISP ISIF Combine the Divided Input Lines

The formatter can gather the divided input lines and organize a single line . Figure 8-194 shows an example generating a single output line from three input lines, and masking two out of three HD input pulses.

Figure 8-194. ISS ISP ISIF Combine Three Input Lines Into Single Line

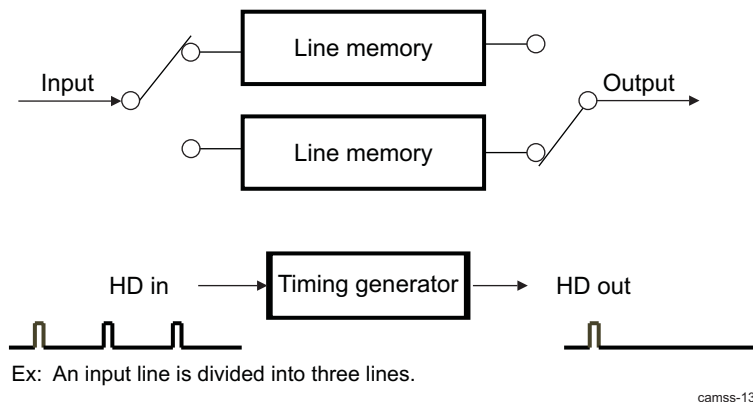

Figure 8-195 is an example that shows the register setting.

- Multiple input lines combined into one output line (use three input lines to one output line in this example)
- Input -> 4, 5, 10, 11, ..., 2, 3, 8, 9, ..., 0, 1, 6, 7, ... (three lines read from sensor)
- Output -> 0, 1, 2, 3, ... (1 line output)
- Register settings:

- ISIF_FMTCFG[0] FMTEN = 0x1
- ISIF_FMTCFG[1] FMTCBL = 0x1
- ISIF_FMTCFG[11:8] FMTAINC = 0x5 (add or subtract 6)
- ISIF_FMTCFG[5:4] LNUM = 0x2
- SETs recycled based on LNUM

8.3.3.7.7 ISS ISP ISIF Color Space Converter

Figure 8-196. ISS ISP ISIF Color Space Converter Block Diagram

The color space converter (CSC) includes four 8-bit × 12-bit multipliers and one adder for the color space conversion. These multiplier/adder units are used for the operation described in Figure 8-197. Data are taken from two input lines during the operation.

Coefficients are signed 8-bit (decimal is 5 bits). Coefficients are set through the following registers:

- Coefficient M00: [ISIF_CSCM0\[7:0\]](#) CSCM00
- Coefficient M01: [ISIF_CSCM0\[15:8\]](#) CSCM01
- Coefficient M02: [ISIF_CSCM1\[7:0\]](#) CSCM02
- Coefficient M03: [ISIF_CSCM1\[15:8\]](#) CSCM03
- Coefficient M10: [ISIF_CSCM2\[7:0\]](#) CSCM10
- Coefficient M11: [ISIF_CSCM2\[15:8\]](#) CSCM11
- Coefficient M12: [ISIF_CSCM3\[7:0\]](#) CSCM12
- Coefficient M13: [ISIF_CSCM3\[15:8\]](#) CSCM13
- Coefficient M20: [ISIF_CSCM4\[7:0\]](#) CSCM20
- Coefficient M21: [ISIF_CSCM4\[15:8\]](#) CSCM21
- Coefficient M22: [ISIF_CSCM5\[7:0\]](#) CSCM22
- Coefficient M23: [ISIF_CSCM5\[15:8\]](#) CSCM23
- Coefficient M30: [ISIF_CSCM6\[7:0\]](#) CSCM30
- Coefficient M31: [ISIF_CSCM6\[15:8\]](#) CSCM31
- Coefficient M32: [ISIF_CSCM7\[7:0\]](#) CSCM32
- Coefficient M33: [ISIF_CSCM7\[15:8\]](#) CSCM33

Figure 8-197. ISS ISP ISIF Color Space Converter Operation

$$\begin{pmatrix} Out1 \\ Out2 \\ Out3 \\ Out4 \end{pmatrix} = \begin{pmatrix} M00 & M01 & M02 & M03 \\ M10 & M11 & M12 & M13 \\ M20 & M21 & M22 & M23 \\ M30 & M31 & M32 & M33 \end{pmatrix} \begin{pmatrix} In1 \\ In2 \\ In3 \\ In4 \end{pmatrix}$$

M00–M33: Signed 8-bit data with 5-bit decimal the value range $-4 \leq M_{xx} < 4$

camss-618

The CSC can convert CMYG filtered CCD data to Bayer matrix (RGBG) data, as shown in Figure 8-198.

Figure 8-198. ISS ISP ISIF Color Space Converter Operation: CMYG to RGBG

camss-113

Figure 8-199 through Figure 8-201 show which input pixels are used for the operation. There is one-line latency between the input and the output.

Figure 8-199. ISS ISP ISIF Color Space Conversion Example

Figure 8-200. ISS ISP ISIF 1st Pixel/1st Line Generation

camss-115

Figure 8-201. ISS ISP ISIF 2nd Pixel/1st Line Generation

camss-116

As shown in [Figure 8-202](#) through [Figure 8-205](#), the operation for the last pixel and the second last pixel uses the same input data.

Figure 8-202. ISS ISP ISIF 2nd Last Pixel/1st Line Generation

camss-117

Figure 8-203. ISS ISP ISIF Last Pixel/1st Line Generation

camss-118

Figure 8-204. ISS ISP ISIF 1st Pixel/Last Line Generation

camss-119

Figure 8-205. ISS ISP ISIF 2nd Pixel/Last Line Generation

camss-120

Also, the operation for the last line and the second last line uses the same input data (see [Figure 8-206](#) and [Figure 8-207](#)).

Figure 8-206. ISS ISP ISIF 2nd Last Pixel/Last Line Generation

camss-121

Figure 8-207. ISS ISP ISIF Last Pixel/Last Line Generation

camss-122

In addition to the registers specific to the color space converter, some of the registers are shared with the input data formatter to configure the valid area:

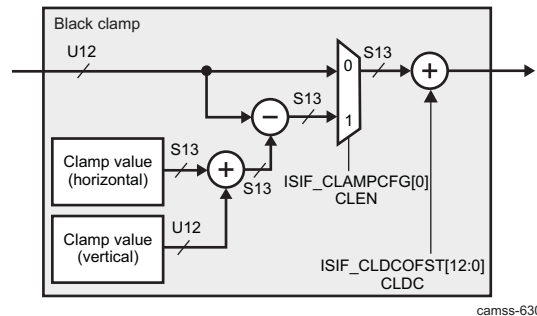

- [ISIF_FMTSPH](#)
- [ISIF_FMTLNH](#)
- [ISIF_FMTLSV](#)
- [ISIF_FMTLNV](#)

There must be at least 1 invalid pixel at the end of the line and one invalid line at the end of the frame.

To enable the color space conversion, set the [ISIF_CSCCTL\[0\]](#) CSCEN bit to 1.

8.3.3.7.8 ISS ISP ISIF Black Clamp

NOTE: For the memory access locations of the ISIF clamp, see [Section 8.3.3.9](#).

Figure 8-208. ISS ISP ISIF Black Clamp Block Diagram

The clamp value is calculated based on the pixel value of the OB region of the sensor. The clamp value is calculated separately for horizontal and vertical directions to compensate the offset drift in both horizontal and vertical directions. The sum of the horizontal and vertical clamp values is subtracted from the image data, and then the additional DC offset is added (the `ISIF_CLDCOFST[12:0]` CLDC bit field, a S13Q0 value). This value is added whether the black clamp module is enabled or not.

The horizontal clamp is disabled through the `ISIF_CLAMPPCFG[2:1]` CLHMD bit field.

To enable the black clamp module, set the `ISIF_CLAMPPCFG[0]` CLEN bit to 1. The `ISIF_PPLN[15:0]` PPLN bit field sets the pixel per line, and the number of pixel clock periods in one line HD period equals `PPLN + 1` pixel clock. The `ISIF_PPLN[15:0]` bit field is not used when the input is already HD/VD.

8.3.3.7.8.1 ISS ISP ISIF Clamp Value for Horizontal Direction

The clamp value for horizontal direction is calculated using the pixel values at the upper OB region.

The maximum pixel value to be used for the clamp value calculation can be limited to 1023 if the pixel value limitation is enabled (`ISIF_CLHWIN0[6]` CLHLMT = 1).

Clamp value calculation for horizontal direction can be disabled in case there is no upper OB region. The operating modes are:

- Horizontal clamp value calculation is enabled. The calculated horizontal clamp value is subtracted from the image data along with the vertical clamp value (`ISIF_CLAMPPCFG[2:1]` CLHMD = 0x1).
- Horizontal clamp value is not updated. The horizontal clamp value used for the previous image is subtracted from the image data along with the vertical clamp value (`ISIF_CLAMPPCFG[2:1]` CLHMD = 0x2).
- Horizontal clamp value is not updated. Only the vertical clamp value is subtracted from the image data (`ISIF_CLAMPPCFG[2:1]` CLHMD = 0x0).

The number of windows in a row is set with the `ISIF_CLHWIN0[4:0]` CLHWC bit field.

Up to 32 windows in a row can be set for clamp value calculation. All the windows have the same size in a format $[2^{(\text{ISIF_CLHWIN0}[9:8] \text{ CLHWM}+5)}]$ pixels by $[2^{(\text{ISIF_CLHWIN0}[13:12] \text{ CLHWN}+1)}]$ lines.

The `ISIF_CLHWIN2[12:0]` CLHSV and `ISIF_CLHWIN1[12:0]` CLHSH bit fields enable setting the position of the first optical black clamp window in the frame. The pixel and line offset are in a range [0:8191]. The `ISIF_HDW` register sets the width of the HD.

Figure 8-209. ISS ISP ISIF Clamp Value for Horizontal Direction

Windows settings details

camss-132

The clamp value for horizontal direction calculation steps are:

1. Calculate the average of the pixel value in each window (ave_win₀ to ave_win_N).

| Calculation Steps | win0 | win1 | win2 | ... | wini | wini + 1 | ... | winN |
|----------------------------|----------------------|----------------------|----------------------|-----|----------------------|------------------------|-----|----------------------|
| Average of the pixel value | ave_win ₀ | ave_win ₁ | ave_win ₂ | | ave_win _i | ave_win _{i+1} | | ave_win _N |

2. Set the average of the left-most window or the right-most window as the base value B_V:

- B_V = ave_win₀ (if ISIF_CLHWIN0[5] CLHWBS = 0x0, case 1)
- B_V = ave_win_N (if ISIF_CLHWIN0[5] CLHWBS = 0x1, case 2)

3. Subtract the base value from the average of each window. Use this value as a clamp value for each window.

| Calculation Steps | win0 | ... | wini | wini+1 | ... | winN |
|-----------------------------|----------------------------------------------------------------|-----|----------------------------------------------------------------|--------------------------------------------------------------------|-----|----------------------------------------------------------------|
| Clamp value for each window | clamp_win ₀ = ave_win ₀ - B _V | | clamp_win _i = ave_win _i - B _V | clamp_win _{i+1} = ave_win _{i+1} - B _V | | clamp_win _N = ave_win _N - B _V |

4. Acquire the horizontal distance (X and CLHWM - X) from the valid pixel to be processed to the center of the closest two windows.
5. Calculate the clamp value of the valid pixel by linear interpolation, using the clamp value of the closest two windows (i and i + 1).
 - Case 1: interpolated_clamp_win_X = (clamp_win_{i+1} - clamp_win_i) * X / CLHWM
 - Case 2: interpolated_clamp_win_X = (clamp_win_i - clamp_win_N) * (CLHWM - X) / CLHWM +

$$(\text{clamp_win}_{i+1} - \text{clamp_win}_N) * X / \text{CLHWM}$$

6. If the valid pixel is on the left of the center of the left-most window, the clamp value of the left-most window is applied. If the valid pixel is on the right of the center of the right-most window, the clamp value of the right-most window is applied.

The clamp values calculated (A), (B) and (C) are:

- Case1: Base is win0 (Left-most window: [ISIF_CLHWIN0](#)[5] CLHWBS = 0x0)
 - (A): zero
 - (B): $(\text{clamp_win}_{i+1} - \text{clamp_win}_i) * X / \text{CLHWM}$
 - (C): $(\text{clamp_win}_N - \text{clamp_win}_0)$
- Case2: Base is winN (Right-most window: [ISIF_CLHWIN0](#)[5] CLHWBS = 0x1)
 - (A): $(\text{clamp_win}_0 - \text{clamp_win}_N)$
 - (B): $(\text{clamp_win}_i - \text{clamp_win}_N) * (\text{CLHWM} - X) / \text{CLHWM} + (\text{clamp_win}_{i+1} - \text{clamp_win}_N) * X / \text{CLHWM}$
 - (C): zero

Each interpolated value $\text{interpolated_clamp_win}_x$ is then subtracted to the associated column.

8.3.3.7.8.2 ISS ISP ISIF Clamp Value for Vertical Direction

The clamp value for vertical direction is calculated using the pixel values at the left or right OB region. Line average is calculated for the OB H valid period ($2^{(\text{ISIF_CLVWIN0}[2:0] \text{ CLVOBH} + 1)}$). The averages for the previous lines are also added back to reduce the difference between the lines, as shown in [Figure 8-210](#).

Figure 8-210. ISS ISP ISIF Clamp Value for Vertical Direction Calculation

- Clamp Value (V_n) = Line Average (V_n) * k + Clamp Value (V_1) * $(1-k)$
- $k = \text{ISIF_CLVWIN0}[15:8] \text{ CLVCOEF}$

The position of the first vertical black clamp window is set with the [ISIF_CLVWIN2](#)[12:0] CLVSV and [ISIF_CLVWIN1](#)[12:0] CLVSH bit fields. The number of vertical windows is set with the [ISIF_CLVWIN3](#)[12:0] CLVOBV bit field. [ISIF_VDW](#) sets the width of the VD.

The accumulator, which holds the vertical clamp value for the previous line, is reset at the beginning of the OB V valid. The reset value can be selected through the [ISIF_CLVWIN0](#)[5:4] CLVRVSL bit field:

- [ISIF_CLVWIN0](#)[5:4] CLVRVSL = 0x0: The base value is calculated for horizontal direction (left-most window win0 or right-most winn set with [ISIF_CLHWIN0](#)[5] CLHWBS).
- [ISIF_CLVWIN0](#)[5:4] CLVRVSL = 0x1: The base value is set through the configuration register ([ISIF_CLVRV](#)[11:0] CLVRV).
- [ISIF_CLVWIN0](#)[5:4] CLVRVSL = 0x2: No update (same as the previous image).

The following figures show the OB valid settings and associated vertical clamp value calculation when OB region is at the left (see [Figure 8-211](#)) and when OB region is at the right (see [Figure 8-212](#)). Each line average value is subtracted from the associated line valid region data.

Figure 8-211. ISS ISP ISIF Clamp Value for Vertical Direction With OB Region at the Left

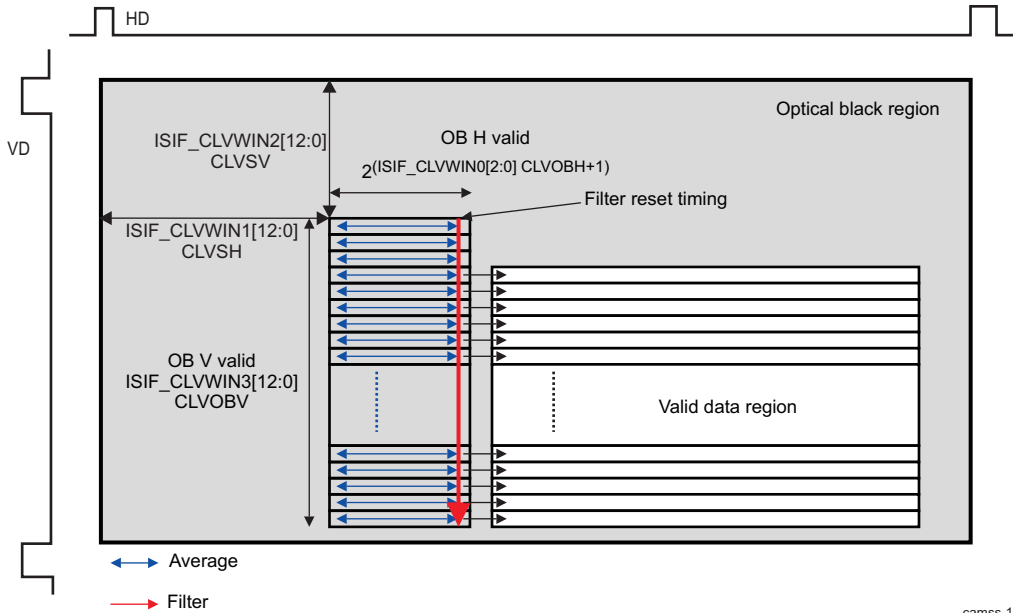

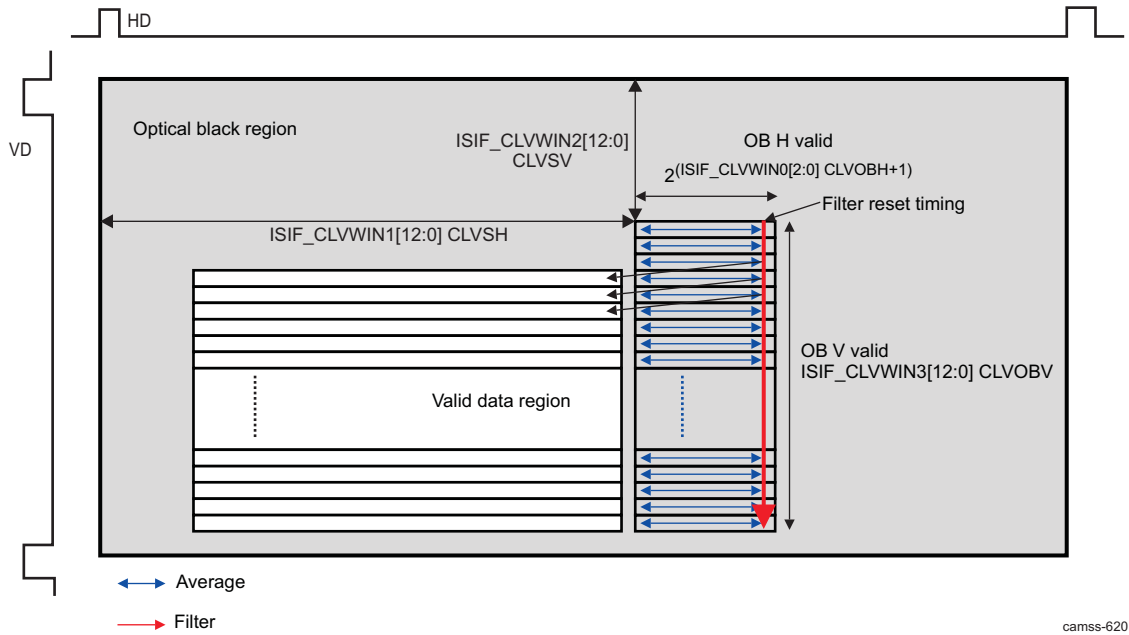

Figure 8-212. ISS ISP ISIF Clamp Value for Vertical Direction With OB Region at the Right

8.3.3.7.9 ISS ISP ISIF Vertical Line Defect Correction (VDFC)

Figure 8-213 shows the block diagram of the vertical line defect (VDFC) correction.

Figure 8-213. ISS ISP ISIF Vertical Line Defect Correction Block Diagram

camss-631

The VDFC block can correct up to eight vertical line defects (see [Figure 8-214](#)).

Figure 8-214. ISS ISP ISIF Vertical Line Defects

camss-134

The correction method is common to all the defects and can be selected through the `ISIF_DFCCTL[6:5]` `VDFCSL` bit field.

There are two different methods to correct vertical line defects (`ISIF_DFCCTL[6:5]` `VDFCSL`):

- Method 1: Data is replaced by an average (`ISIF_DFCCTL[6:5]` `VDFCSL` = 0x2):
 - The defect is replaced by the average of pixel $(i - 2)$ and pixel $(i + 2)$
- Method 2: Data is subtracted by a defect level (`ISIF_DFCCTL[6:5]` `VDFCSL` = 0x0 or 0x1):
 - A saturation level is defined in the `ISIF_VDFSATLV[11:0]` `VDFSLV` bit field.
 - The coordinates of the defect:
 - Are defined in the `ISIF_DFCMEM0[12:0]` `DFCMEM0` and `ISIF_DFCMEM1[12:0]` `DFCMEM1` bit fields
 - Are 13 bits wide for horizontal and vertical direction, so an image size up to 8192 × 8192 is supported
 - If the data is not saturated ($\text{data} < \text{VDFSLV}$):
 - The defect is corrected by subtracting the defect level. A different defect level is defined for:
 - The point of the defect ($V = V_{\text{defect}}$): SUB1 defect level is defined in the `ISIF_DFCMEM2[7:0]` `DFCMEM2` bit field.
 - The pixels lower than the defect ($V < V_{\text{defect}}$): SUB2 defect level is defined in the `ISIF_DFCMEM3[7:0]` `DFCMEM3` bit field.
 - The pixels upper than the defect ($V > V_{\text{defect}}$): Defect level is defined in the `ISIF_DFCMEM4[7:0]` `DFCMEM4` bit field.
 - Each defect level (value to be subtracted from the data) described previously can be up-shifted through the `ISIF_DFCCTL[10:8]` `VDFLSFT` bit field.
 - Vertical line defect correction for upper pixels can be disabled through the `ISIF_DFCCTL[7]` `VDFCUDA` bit.
 - If the data is saturated (`VDFSLV`), there are two possibilities:
 - `ISIF_DFCCTL[6:5]` `VDFCSL` = 0x0: Data is simply fed through (not subtracted)
 - `ISIF_DFCCTL[6:5]` `VDFCSL` = 0x1: Horizontal interpolation $((i - 2) + (i + 2))/2$ (data is replaced by

interpolation or data is subtracted with interpolation)

The [ISIF_LPFR](#) register sets the number of half lines per frame or field: VD period = (L PFR+ 1)/2 lines. LPFR is not used when HD and VD are inputs.

The following paragraphs concern only method 2 correction.

The coordinates of the defects and the defect levels to be subtracted from the data must be set to the processing shown in [Table 8-340](#).

Table 8-340. ISS ISP ISIF Vertical Line Defect Table in Memory

| Bit | Defect Information |
|-------|------------------------------------------------------------------------------|
| 12:0 | Vertical position of the defects |
| 25:13 | Horizontal position of the defects |
| 33:26 | Defect level of the vertical line defect position (V = Vdefect) |
| 41:34 | Defect level of the pixels upper than the vertical line defect (V < Vdefect) |
| 49:42 | Defect level of the pixels lower than the vertical line defect (V > Vdefect) |

The defect must be set from left to right, as shown in [Figure 8-215](#).

Figure 8-215. ISS ISP ISIF Vertical Line Defects

camss-135

Vertical line defect correction is enable by setting the [ISIF_DFCCTL\[4\]](#) VDFCEN bit to 1, but the procedure explained in [Section 8.3.3.7.9.1](#), *ISS ISP ISIF Vertical Line Defect Table Update Procedure*, must be respected.

8.3.3.7.9.1 ISS ISP ISIF Vertical Line Defect Table Update Procedure

The following procedure must be respected to write the vertical line defect table in memory.

1. [ISIF_DFCMEMCTL\[4\]](#) DFCMCLR = 0x1
2. Ensure that [ISIF_DFCCTL\[4\]](#) VDFCEN is disabled (0x0).
3. Write the V coordinate of the first defect to the [ISIF_DFCMEM0\[12:0\]](#) DFCMEM0 bit field.
4. Write the H coordinate of the first defect to the [ISIF_DFCMEM1\[12:0\]](#) DFCMEM1 bit field.
5. Set the defect level to:
 - [ISIF_DFCMEM2\[7:0\]](#) DFCMEM2
 - [ISIF_DFCMEM3\[7:0\]](#) DFCMEM3
 - [ISIF_DFCMEM4\[7:0\]](#) DFCMEM4
6. Set the [ISIF_DFCMEMCTL\[0\]](#) DFCMWR bit to 1 with the [ISIF_DFCMEMCTL\[2\]](#) DFCMARST bit set to 1.
7. Wait until the [ISIF_DFCMEMCTL\[0\]](#) DFCMWR bit is cleared.
8. Write the next data to:
 - [ISIF_DFCMEM0\[12:0\]](#) DFCMEM0

- [ISIF_DFCMEM1\[12:0\]](#) DFCMEM1
 - [ISIF_DFCMEM2\[7:0\]](#) DFCMEM2
 - [ISIF_DFCMEM3\[7:0\]](#) DFCMEM3
 - [ISIF_DFCMEM4\[7:0\]](#) DFCMEM4
9. Set the [ISIF_DFCMEMCTL\[0\]](#) DFCMWR bit to 1 with the [ISIF_DFCMEMCTL\[2\]](#) DFCMARST bit cleared.
 10. Repeat 4~5 times until all entries (up to 8) are written to the vertical line defect table.
 11. In case the defect entry is less than 8, an extra write cycle is required to fill the next table location with a certain value.
 12. Clear the [ISIF_DFCMEM0\[12:0\]](#) DFCMEM0 bit field to all 0, set the [ISIF_DFCMEM1\[12:0\]](#) DFCMEM1 to all 1, and set the [ISIF_DFCMEMCTL\[0\]](#) DFCMWR bit to 1 with the [ISIF_DFCMEMCTL\[2\]](#) DFCMARST bit cleared.
 13. Enable VDFC by setting the [ISIF_DFCCTL\[1\]](#) VDFCEN bit.

8.3.3.7.10 ISS ISP ISIF Lens Shading Correction (2D-LSC)

NOTE: For the memory access locations of the 2D-LSC table, see [Section 8.3.3.9](#).

Figure 8-216. ISS ISP ISIF 2D-LSC Block Diagram

LSC is useful for correcting optical artifacts that cause image brightness to decrease starting from the center of the image and going out to the edges.

The LSC module implements a per pixel offset and gain adjustment in the RAW Bayer domain (2 × 2 color pattern). The offset is applied before gain multiplication.

The offset and gains are stored in a LUT, which is stored in SDRAM and is loaded in real time. The submodule prefetches the data from SDRAM such that no underflow occurs. Underflow occurs when the offset and gain data required for the current pixel are not available.

The data stored in the LUT is downsampled; that is, there is no gain or offset per pixel. The downsampling factor is programmable. High downsampling ratios lead to a smaller LUT, lower accuracy, and lower memory bandwidth. A low downsampling ratio leads to a bigger LUT, higher accuracy, and higher memory bandwidth.

When the offset and gain values are loaded, they are upsampled to the incoming image resolution. The missing table values are computed through bilinear interpolation.

To enable the 2D-LSC module, set the [ISIF_2DLSCCFG\[0\]](#) ENABLE bit to 1.

8.3.3.7.10.1 ISS ISP ISIF 2D-LSC Active Region Settings

The gain and offset maps are internally up-sampled to full resolution before being applied to the image. In order to account for all the possible cropping schemes and zoom ratios, the 2D-LSC can be configured such that a single gain map can be stored in memory that maps to sensor lens. The 2D-LSC active region is defined by [Figure 8-217](#).

Figure 8-218. ISS ISP ISIF Gain and Offset Mask Upsampling via Bilinear Interpolation

The gain table format is set in the [ISIF_2DLSCCFG\[3:1\] GAIN_FORMAT](#) bit field. 8-bit entries are supported in the gain map (in U8Q8, U8Q7, U8Q6, and U8Q5 format with optional base of 1.0 to shift the range up).

8-bit entries are supported in the offset map (in S8Q0 format). An optional shifting up for offsets is possible. The shift up value is selected through the [ISIF_2DLSCOFST\[6:4\] OFSTSFT](#) bit field. A scaling factor for offsets is defined in the [ISIF_2DLSCOFST\[15:8\] OFSTSF](#) bit field.

The offset control in the 2D-LSC module can be enabled or disabled through the [ISIF_2DLSCOFST\[0\] OFSTEN](#) bit.

For an LSC active region size of $W \times H$ (the output and input are the same size), and the gain and offset maps are $M \times N$ downsampled, a table with the following values is needed:

- $(\text{ceil}[(X + W) / M] + 1) \times (\text{ceil}[(Y + H) / N] + 1) \times 4$ bytes data in external memory organized as:
 - $(\text{ceil}[(\text{Init}X + W) / M] + 1)$ lines of data
 - Each line having at least $(\text{ceil}[(\text{Init}Y + H) / N] + 1) \times 4$ data points
- Extra data at end of each line can be skipped by the line offset register parameter:
- For gain map:
 - Line offset: [ISIF_2DLSCGROF\[15:0\] OFFSET](#)
 - For offset map:
 - Line offset: [ISIF_2DLSCOROF\[15:0\] OFFSET](#)
 - Each line offset must start at a 32-bit aligned boundary.

8.3.3.7.10.1.2 ISS ISP ISIF 2D-LSC Gain and Offset Table Upsampling

Upsampling of the pixel-by-pixel gains is performed by locating the four same-color anchors for each destination gain value and applying bilinear interpolation.

The gain and offset mask function is neutral to color pattern. The starting color of the gain and offset mask must be consistent with the starting color of the image, and can be any color. To align starting colors, the X and Y values must be even. The 2D-LSC engine upsamples each phase of the mask data as a separate plane and applies the upsampled mask to the image with the same color phasing. In other words, the red gains are interpolated with red gains, and applied to the red input pixels. The same is done for each of the other three colors in the color pattern. The 2D-LSC module is designed to work with Bayer CFA data, having the R/Gr/Gb/B color pattern. For the purpose of functional description, assume red is the starting color, but any other starting color or other 2 x 2 pattern can be used by placing color gains in the appropriate order.

8.3.3.7.10.1.3 ISS ISP ISIF Application of Gain and Offset to Image Pixels

The gain value interpolated for each pixel is multiplied with a corresponding input pixel. An offset is applied before the gain. The product is rounded to the nearest integer and then clipped or saturated to the valid range of 13 bits.

The following equation describes the operation of the LSC in terms of offset and gain:

$$\text{out}[x,y] = (\text{in}[x,y] + a * (\text{ofst}[x,y] \ll T)) * \text{gain}[x,y] \quad (6)$$

- in[x, y] are the input pixels, 13 bits signed.
- ofst[x, y] are the upsampled offset points.
- T is the upshift value applied to the result of the offset interpolation points (0 – 5) set through the [ISIF_2DLSCOFST\[6:4\]](#) OFSTSFT bit field.
- a is the offset gain value in U8Q7 format set through the [ISIF_2DLSCOFST\[15:8\]](#) OFSTSF bit field.
- gain[x, y] are the upsampled gain points.
- out[x, y] are the resulting output pixels, 13 bits signed.

8.3.3.7.10.1.4 ISS ISP ISIF Enabling/ Disabling the 2D-LSC Module

LSC operates on a single frame or continuously, depending on the firmware programming.

Upon power-on reset (POR), the 2D-LSC module is disabled and input pixels are copied to the output, bypassing any shading operation.

When enabling or disabling the 2D-LSC, caution must be taken on the timing of register modifications. To avoid causing a prefetch error or other unexpected behavior, the following safeguards must be implemented:

1. While configuring the 2D-LSC registers, the input clock into the ISIF should be toggling.
2. All of the 2D-LSC registers must be configured appropriately before enabling the [ISIF_2DLSCCFG\[0\]](#) ENABLE bit.
3. After setting the ENABLE bit to 1, the hardware immediately begins fetching the first two rows of gain and offset data entries from external memory. When this is complete, the [ISIF_2DLSCIRQST\[2\]](#) PREFETCH_COMPETED status flag is set.

NOTE: If the ENABLE bit is disabled before the [ISIF_2DLSCIRQST\[3\]](#) SOF status flag is set, the [ISIF_2DLSCIRQST\[1\]](#) PREFETCH_ERROR flag is set and the state of the 2D-LSC submodule may lead to unexpected errors. Therefore, the ENABLE bit must not be disabled until after the [ISIF_2DLSCIRQST\[3\]](#) SOF status flag is set.

4. Appropriate gains and offsets are applied to the image pixels. Pixels outside the LSC active region are passed through unaltered. When the 2D-LSC operation on the active region completes, the [ISIF_2DLSCIRQST\[0\]](#) DONE status flag is set.
5. At this point:
 - If the ENABLE bit is still set to 1, the hardware immediately begins to prefetch the gain and offset data entries for the next frame and waits for the active region of the next frame to arrive.
 - If the ENABLE bit is set to 0, it stops LSC operation once the active region is passed, and goes into idle until the ENABLE bit is written to 1 again.

NOTE: To provide a mechanism for firmware to recover from the LSC module waiting indefinitely for the input image, if LSC_ENABLE is written to 0 after it has started gain/offset map prefetching, but before the LSC gets to the next active region, the LSC operation is aborted and turned idle, and any prefetched gain/offset entries are discarded. This can happen before or after the next start-of-frame.

NOTE: Therefore, because of the constraints set in point 3, the ENABLE register bit must be disabled only after the [ISIF_2DLSCIRQST\[3\]](#) SOF status flag is set and before the [ISIF_2DLSCIRQST\[0\]](#) DONE status flag is set for that same frame.

It is suggested that when the 2D-LSC or the whole ISIF needs to be disabled for switching modes, the [ISIF_2DLSCIRQST\[3\]](#) SOF interrupt be enabled so that software knows when it is safe to disable the 2D-LSC. Then the ISIF can be disabled after the [ISIF_2DLSCIRQST\[0\]](#) DONE status signal is set for that frame.

NOTE: The LSC_ENABLE bit, once written to 1, must not be cleared until at least one vpi_clk clock cycle after start-of-frame, to ensure correct processing.

8.3.3.7.10.1.5 ISS ISP ISIF 2D-LSC Events and Status Checking

The 2D-LSC submodule can generate events on a single interrupt line. These events are further remapped at the ISP level in `ISP5_IRQENABLE_SET__0.ISIF_INT_3` - `ISP5_IRQENABLE_SET__3.ISIF_INT3`.

Four 2D-LSC events can be generated:

- **DONE:** LSC done. This event triggers when the LSC submodules transition from ACTIVE state to IDLE state.
- **PREFETCH_ERROR:** Gain table prefetch error. This event triggers when the tables stored in SDRAM are read too slowly. After this event is asserted, the LSC disables the LSC computation until the beginning of the next frame.
- **PREFETCH_COMPLETE:** Gain table prefetch complete. This event triggers when data prefetching from SDRAM completes. Data prefetching must complete by the time the first pixel of a frame comes. The event triggers when the buffer contains three full rows of data.
- **SOF:** This event signals the start of the LSC valid region. The LSC configuration registers for the next frame can be updated after the LSC SOF triggers.

The [ISIF_2DLSCIRQEN](#) register can be configured to select which events are masked and which are propagated to the LSC interrupt signal. The [ISIF_2DLSCIRQST](#) register can be read and cleared to identify which events have occurred.

In addition, the 2D-LSC module provides the following status bit:

- **BUSY:** This indicates that LSC has entered the active region vertically. This bit remains on during horizontal blanking, and turns off only after the entire active region of the current frame is processed.

8.3.3.7.10.1.6 ISS ISP ISIF Supported On-the-Fly 2D-LSC Configurations

The 2D-LSC prefetch memory is equal to $2 \times 1536 \times 32$ bits. This memory is sized to fetch three lines of 8-bit gain and 8-bit offset \times four color components per paxel. Given an image sensor of horizontal resolution H, there are $\text{floor}[(H / \text{ISIF_2DLSCCFG}[14:12] \text{ GAIN_MODE_M}) + 1]$ paxels per line, where M is the horizontal LSC paxel size.

[Table 8-341](#) shows the LSC horizontal paxel size, which can be supported for different image sensor resolutions. When $M = 8$, some resolutions cannot be supported on the fly (orange-shaded cells in the table); the way to process such large images is to use vertical frame division.

Table 8-341. ISS ISP ISIF Supported On-the-Fly LSC Configurations

| MPix | Aspect Ratio | | Line Size | Horizontal LSC Pixel Size: $M = 2^{\lfloor \text{ISIF_2DLSCCFG}[14:12] \text{ GAIN_MODE_M} \rfloor}$ | | | | |
|---------|--------------|---|-----------|---------------------------------------------------------------------------------------------------------|------|-----|-----|-----|
| | | | | 8 | 16 | 32 | 64 | 128 |
| Maximum | – | – | 5376 | 2019 | 1011 | 507 | 255 | 129 |
| 16 | 16 | 9 | 5333 | 2003 | 1003 | 503 | 253 | 128 |
| 16 | 4 | 3 | 4619 | 1735 | 869 | 436 | 220 | 111 |
| 16 | 3 | 2 | 4899 | 1840 | 922 | 462 | 233 | 118 |
| 12 | 16 | 9 | 4619 | 1735 | 869 | 436 | 220 | 111 |
| 12 | 4 | 3 | 4000 | 1503 | 753 | 378 | 191 | 97 |
| 12 | 3 | 2 | 4243 | 1594 | 798 | 401 | 202 | 102 |
| 10 | 16 | 9 | 4216 | 1584 | 794 | 398 | 201 | 102 |

| 8 | 4 | 3 | 3266 | 1228 | 615 | 309 | 156 | 80 |
| 8 | 3 | 2 | 3464 | 1302 | 653 | 328 | 165 | 84 |

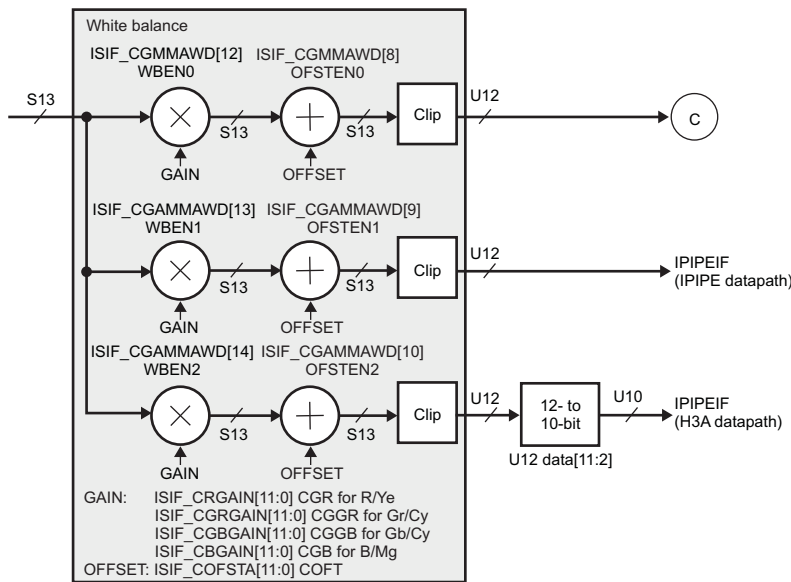

8.3.3.7.10.1.7 ISS ISP ISIF Bandwidth Requirements on BL Read Port

See Section 8.3.3.7.18.2 for details.

8.3.3.7.11 ISS ISP ISIF White Balance

Figure 8-219 shows the white balance block diagram.

Figure 8-219. ISS ISP ISIF White Balance Block Diagram

Color pattern settings are set through the **ISIF_CCOLP** register. Moreover, through this register the pixel position from 0 to 3 can be set to the needed Bayer universal camera filter color pattern (RGB/CYGM).

The CFA pattern can be in two modes, stripe or mosaic, and is set through the **ISIF_CGAMMAWD[5]** CFAP bit.

There are color-dependent gain controls for the three outputs: BL output, IPIPEIF (IPIPE path) output, and IPIPEIF (H3A path) output. Gain applied to each data is selected according to the pixel position and the color pattern settings. Gain factors are common for the three data paths. Gain is in U11Q9 format, which ranges from 0 to 3 + 511/512. The gain factor is set through the following registers:

- R/Ye gain: `ISIF_CRGAIN[11:0]` CGR
- Gr/Cy gain: `ISIF_CGRGAIN[11:0]` CGGR
- Gb/Cy gain: `ISIF_CGBGAIN[11:0]` CGGB
- B/Mg gain: `ISIF_CBGAIN[11:0]` CGB

Gain control can be enabled or disabled individually for each path.

- Enable or disable gain for the BL path: `ISIF_CGAMMAWD[12]` WBEN0
- Enable or disable gain for the IPIPEIF (IPIPE) path: `ISIF_CGAMMAWD[13]` WBEN1
- Enable or disable gain for the IPIPEIF (H3A) path: `ISIF_CGAMMAWD[14]` WBEN2

After the gain control, a single offset value can be added to each path individually. This offset is common for the three paths and is set through the `ISIF_COFSTA[11:0]` COFT bit field. The offset value is U12, which ranges from 0 to 4095. Data (S13) are then truncated to U12.

- Enable or disable offset for the BL path: `ISIF_CGAMMAWD[8]` OFSTEN0
- Enable or disable offset for the IPIPEIF (IPIPE) path: `ISIF_CGAMMAWD[9]` OFSTEN1
- Enable or disable offset for the IPIPEIF (H3A) path: `ISIF_CGAMMAWD[10]` OFSTEN2

8.3.3.7.12 ISS ISP ISIF Low-Pass Filter (LPF)

Figure 8-220 shows the low-pass filter block diagram.

Figure 8-220. ISS ISP ISIF Low-Pass Filter Block Diagram

An optional horizontal low-pass anti-aliasing filter (LPF) can be applied (the `ISIF_MODESET[14]` HLPF bit) after reframing. The low-pass filter consists of a simple 3-tap (1/4, 1/2, and 1/4) filter. Two pixels on the left and two pixels on the right of each line are cropped if the filter is enabled. Use of the LPF is intended for bandwidth reduction if culling is enabled.

NOTE: For YUV data, the LPF must be disabled (`ISIF_MODESET[14]` HLPF = 0x0).

8.3.3.7.13 ISS ISP ISIF A-Law Compression

Figure 8-221 shows the A-Law compression block diagram.

Figure 8-221. ISS ISP ISIF A-Law Compression Block Diagram

An optional 10-to-8-bit A-Law compression using a fixed A-Law table can be applied (`ISIF_CGAMMAWD[0] CCDTBL`) as the final processing stage. Using this compression causes the data width to be reduced to 8 bits and allows packing to 8 bits/pixel when saving to memory. Because data resolution can be greater than 10 bits at this stage, the 10 bits for input to the A-Law operation must be selected (`ISIF_CGAMMAWD[4:1] GWDI`).

The IPIPEIF module has an inverse A-Law table (A-Law decompression) option so that this nonlinear operation can be reversed if this saved data is to be read back in for further processing.

NOTE: Do not use A-Law compression (`ISIF_CGAMMAWD[0] CCDTBL = 0`) with YUV data.

Figure 8-222 shows the A-Law table diagram, and Figure 8-223 shows the A-Law table values.

Figure 8-222. ISS ISP ISIF A-Law Table Diagram

Figure 8-223. ISS ISP ISIF A-Law Table Values

| Input | A-Law | Input | A-Law | Input | A-Law | Input | A-Law | Input | A-Law | Input | A-Law | Input | A-Law | Input | A-Law |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| 0 | 0 | 64 | 64 | 128 | 112 | 192 | 140 | 256 | 161 | 320 | 176 | 384 | 189 | 448 | 200 |
| 1 | 1 | 65 | 65 | 129 | 113 | 193 | 141 | 257 | 161 | 321 | 176 | 385 | 189 | 449 | 200 |
| 2 | 2 | 66 | 66 | 130 | 113 | 194 | 141 | 258 | 161 | 322 | 177 | 386 | 189 | 450 | 200 |
| 3 | 3 | 67 | 67 | 131 | 114 | 195 | 142 | 259 | 161 | 323 | 177 | 387 | 189 | 451 | 200 |
| 4 | 4 | 68 | 68 | 132 | 114 | 196 | 142 | 260 | 162 | 324 | 177 | 388 | 190 | 452 | 200 |
| 5 | 5 | 69 | 69 | 133 | 115 | 197 | 142 | 261 | 162 | 325 | 177 | 389 | 190 | 453 | 200 |
| 6 | 6 | 70 | 70 | 134 | 115 | 198 | 143 | 262 | 162 | 326 | 177 | 390 | 190 | 454 | 201 |
| 7 | 7 | 71 | 71 | 135 | 116 | 199 | 143 | 263 | 162 | 327 | 178 | 391 | 190 | 455 | 201 |
| 8 | 8 | 72 | 72 | 136 | 116 | 200 | 143 | 264 | 163 | 328 | 178 | 392 | 190 | 456 | 201 |
| 9 | 9 | 73 | 73 | 137 | 117 | 201 | 144 | 265 | 163 | 329 | 178 | 393 | 190 | 457 | 201 |
| 10 | 10 | 74 | 74 | 138 | 117 | 202 | 144 | 266 | 163 | 330 | 178 | 394 | 191 | 458 | 201 |
| 11 | 11 | 75 | 75 | 139 | 118 | 203 | 144 | 267 | 163 | 331 | 178 | 395 | 191 | 459 | 201 |
| 12 | 12 | 76 | 76 | 140 | 118 | 204 | 145 | 268 | 164 | 332 | 179 | 396 | 191 | 460 | 201 |
| 13 | 13 | 77 | 77 | 141 | 119 | 205 | 145 | 269 | 164 | 333 | 179 | 397 | 191 | 461 | 202 |
| 14 | 14 | 78 | 78 | 142 | 119 | 206 | 145 | 270 | 164 | 334 | 179 | 398 | 191 | 462 | 202 |
| 15 | 15 | 79 | 78 | 143 | 120 | 207 | 146 | 271 | 164 | 335 | 179 | 399 | 191 | 463 | 202 |
| 16 | 16 | 80 | 79 | 144 | 120 | 208 | 146 | 272 | 165 | 336 | 179 | 400 | 192 | 464 | 202 |
| 17 | 17 | 81 | 80 | 145 | 121 | 209 | 146 | 273 | 165 | 337 | 180 | 401 | 192 | 465 | 202 |
| 18 | 18 | 82 | 81 | 146 | 121 | 210 | 147 | 274 | 165 | 338 | 180 | 402 | 192 | 466 | 202 |
| 19 | 19 | 83 | 82 | 147 | 122 | 211 | 147 | 275 | 166 | 339 | 180 | 403 | 192 | 467 | 202 |
| 20 | 20 | 84 | 83 | 148 | 122 | 212 | 147 | 276 | 166 | 340 | 180 | 404 | 192 | 468 | 203 |
| 21 | 21 | 85 | 84 | 149 | 123 | 213 | 148 | 277 | 166 | 341 | 181 | 405 | 193 | 469 | 203 |
| 22 | 22 | 86 | 84 | 150 | 123 | 214 | 148 | 278 | 166 | 342 | 181 | 406 | 193 | 470 | 203 |
| 23 | 23 | 87 | 85 | 151 | 124 | 215 | 148 | 279 | 167 | 343 | 181 | 407 | 193 | 471 | 203 |
| 24 | 24 | 88 | 86 | 152 | 124 | 216 | 149 | 280 | 167 | 344 | 181 | 408 | 193 | 472 | 203 |
| 25 | 25 | 89 | 87 | 153 | 125 | 217 | 149 | 281 | 167 | 345 | 181 | 409 | 193 | 473 | 203 |
| 26 | 26 | 90 | 88 | 154 | 125 | 218 | 149 | 282 | 167 | 346 | 182 | 410 | 193 | 474 | 204 |
| 27 | 27 | 91 | 88 | 155 | 125 | 219 | 150 | 283 | 168 | 347 | 182 | 411 | 194 | 475 | 204 |
| 28 | 28 | 92 | 89 | 156 | 126 | 220 | 150 | 284 | 168 | 348 | 182 | 412 | 194 | 476 | 204 |
| 29 | 29 | 93 | 90 | 157 | 126 | 221 | 150 | 285 | 168 | 349 | 182 | 413 | 194 | 477 | 204 |
| 30 | 30 | 94 | 91 | 158 | 127 | 222 | 151 | 286 | 168 | 350 | 182 | 414 | 194 | 478 | 204 |
| 31 | 31 | 95 | 91 | 159 | 127 | 223 | 151 | 287 | 168 | 351 | 183 | 415 | 194 | 479 | 204 |
| 32 | 32 | 96 | 92 | 160 | 128 | 224 | 151 | 288 | 169 | 352 | 183 | 416 | 194 | 480 | 204 |
| 33 | 33 | 97 | 93 | 161 | 128 | 225 | 152 | 289 | 169 | 353 | 183 | 417 | 195 | 481 | 205 |
| 34 | 34 | 98 | 93 | 162 | 129 | 226 | 152 | 290 | 169 | 354 | 183 | 418 | 195 | 482 | 205 |
| 35 | 35 | 99 | 94 | 163 | 129 | 227 | 152 | 291 | 169 | 355 | 183 | 419 | 195 | 483 | 205 |
| 36 | 36 | 100 | 95 | 164 | 129 | 228 | 152 | 292 | 170 | 356 | 184 | 420 | 195 | 484 | 205 |
| 37 | 37 | 101 | 96 | 165 | 130 | 229 | 153 | 293 | 170 | 357 | 184 | 421 | 195 | 485 | 205 |
| 38 | 38 | 102 | 96 | 166 | 130 | 230 | 153 | 294 | 170 | 358 | 184 | 422 | 195 | 486 | 205 |
| 39 | 39 | 103 | 97 | 167 | 131 | 231 | 153 | 295 | 170 | 359 | 184 | 423 | 196 | 487 | 205 |

8.3.3.7.14 ISS ISP ISIF Culling

Figure 8-224 shows the culling block diagram.

Figure 8-224. ISS ISP ISIF Culling Block Diagram

The culling block performs a programmable decimation function for horizontal, vertical, and YUV4:2:2 data directions. The horizontal and vertical decimation of image data can be controlled by two registers.

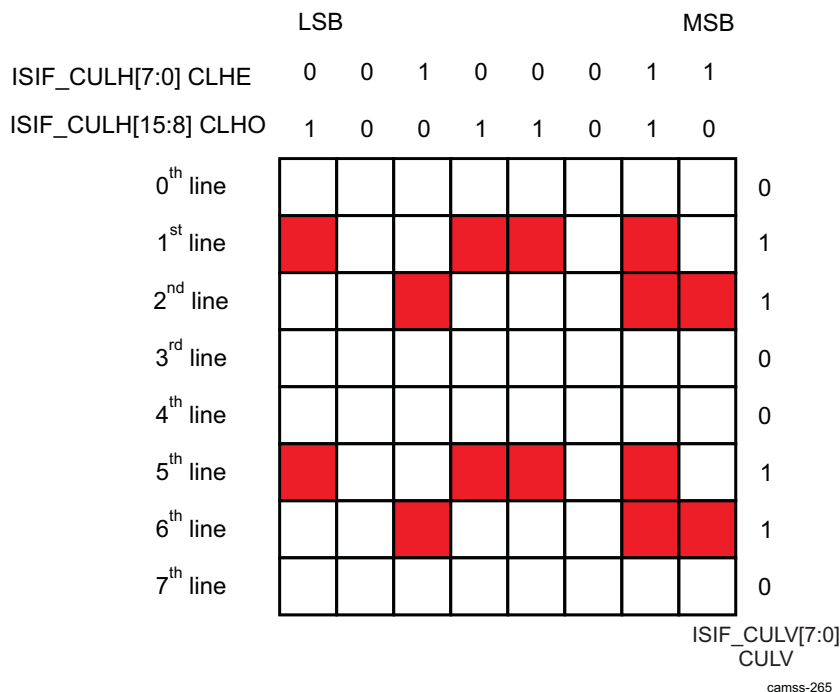

The horizontal culling operation allows selected pixel data to be culled (deleted) from a line. The [ISIF_CULH](#) register specifies the horizontal culling pattern for even and odd lines:

- Even lines: [ISIF_CULH](#)[15:8] CLHE
- Odd lines: [ISIF_CULH](#)[16:0] CLHO

The vertical culling operation allows selected lines to be culled from a frame. The [ISIF_CULV](#) register specifies the pattern for the vertical direction. The LSBs of CULV represent the top line of the CCD; the MSB is the seventh line.

[Figure 8-225](#) is an example of how register values apply the decimation pattern to the data. The red pixels are saved to memory and the white pixels are discarded. In this example, $CULH = 0x59C4$ and $CULV = 0x0066$.

NOTE: Culling can be used with YUV data, but care must be taken to preserve the YUV4:2:2 output format.

Figure 8-225. ISS ISP ISIF Example for Decimation Pattern

8.3.3.7.15 ISS ISP ISIF 12-to-8 bit DCPM Compression Block

In ISIF, there is a DCPM compression block, which is between the culling module and the storage formatter module. This block can compress 12-bit image data to 8 bits for bandwidth reduction in transmission between the ISIF and SDRAM. An 8- to-12-bit DCPM decoder at the IPIPEIF decompresses data for IPIPE processing.

Two different predictors are used for the compression system. The first predictor is simple (simple predictor), and the second predictor is slightly more complex (advanced predictor). Because the advanced predictor gives a slightly better prediction for the pixel value, the image quality can be improved using it. Because the simple predictor is very simple, the processing power and memory requirements are reduced using it, when the image quality is already sufficiently high.

- Advanced predictor: This predictor uses only the previous same color component value as a prediction value. Therefore, only 2-pixel memory is required.
- This predictor uses four previous pixel values when the prediction value is evaluated. This means that the other color component values are also used when the prediction value has been defined.

The function is controlled from the [ISIF_MISC\[12\] DPCMEN](#) and [ISIF_MISC\[13\] DPCMPRE](#) bits.

8.3.3.7.16 ISP ISIF Storage Formatter

Figure 8-226 shows the storage formatter block diagram.

Figure 8-226. ISS ISP ISIF Storage Formatter Block Diagram

Data are stored to the lower bits of a 16-bit SDRAM word, or can be 8- or 12-bit packed. The [ISIF_HSIZE\[11:0\]](#) HSIZE bit field can specify the memory address offsets between lines of memory (offset in 32-byte units). If set, the [ISIF_HSIZE\[12\]](#) ADCR bit can decrement the memory address line and the line can be horizontally flipped in memory.

In case of RAW data, a data shift module is used: data to be stored can be right-shifted according to the value set at the [ISIF_MODESET\[10:8\]](#) CCDW bit field, as described in [Table 8-342](#).

Table 8-342. ISS ISP ISIF RAW Data Shifting

| ISIF_MODESET[10:8] CCDW | Output Format |
|-------------------------|--------------------------------------------|
| | MSB LSB |
| 000 | 0000 & U12 data[11:0] |
| 001 | 00000 & U12 data[11:1] |
| 010 | 000000 & U12 data[11:2] |
| 011 | 0000000 & U12 data[11:3] |
| 100 | 00000000 & U12 data[11:4] |

Table 8-343 shows the format where data are stored to the lower bits of a 16-bit word and the format where data are packed to 8 bits. The unused bits are filled with zeros.

Table 8-343. ISS ISP ISIF SDRAM Data Format

| | Upper Word | | Lower Word | |
|--------------|------------|---------|------------|---------|
| | MSB(31) | LSB(16) | MSB(15) | LSB(0) |
| 12 bit | 0 | Pixel 1 | 0 | Pixel 0 |
| 11 bit | 0 | Pixel 1 | 0 | Pixel 0 |
| 10 bit | 0 | Pixel 1 | 0 | Pixel 0 |
| 9 bit | 0 | Pixel 1 | 0 | Pixel 0 |
| 8 bit | 0 | Pixel 1 | 0 | Pixel 0 |
| 8-bit packed | Pixel 3 | Pixel 2 | Pixel 1 | Pixel 0 |

Table 8-344 shows the format where data are packed to 12 bits.

Table 8-344. ISS ISP ISIF SDRAM Data Format for 12-bit Packed

| | Upper Word | | Lower Word | |
|--------|-------------|---------|--------------|--------------|
| | MSB(31) | LSB(16) | MSB(15) | LSB(0) |
| 12 bit | Pixel2[7:0] | Pixel1 | Pixel 0 | |
| | Pixel5[3:0] | Pixel4 | Pixel3 | Pixel2[11:8] |
| | Pixel7 | Pixel6 | Pixel5[11:4] | |

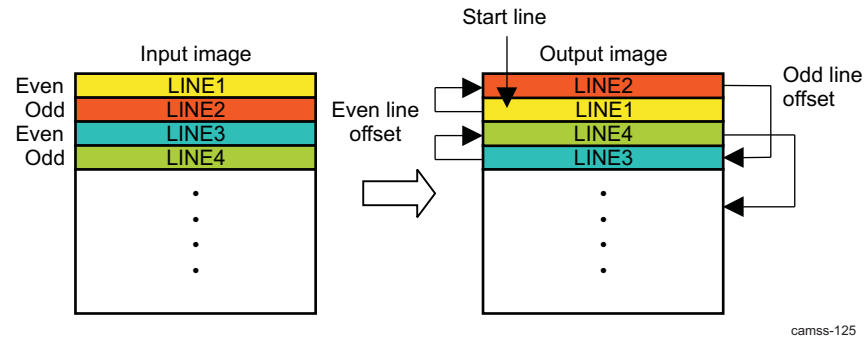

In case of YUV, YUV data is stored in memory in packed YUV4:2:2 mode, using 2 pixels per 32 bits, as shown in Table 8-345.

The output formatter can configure to any image format by using the SDRAM line offset register and offset control registers. Figure 8-227 shows how to construct a frame format in SDRAM. The ISIF_CADU[10:0] CADU bit field specifies the memory destination (upper 11 bits) to SDRAM (the address is the value of the set bit multiplied by 32 bytes). On the other hand, the ISIF_CADL[15:0] CADL bit field sets the memory destination to SDRAM (lower 16 bits) (the address is the value of the set bit multiplied by 32 bytes).

8.3.3.7.17 ISS ISP ISIF YCbCr signal Processing

The ISIF accepts 4:2:2 sampled YCbCr input data. The luminance and color difference signals are 8 bits each, scaled 0 to 255. The color difference signals are multiplexed into one 8-bit bus beginning with a Cb sample. The Y and CbCr buses can be input parallel (16-bit mode) or be time multiplexed and input as a single bus (8-bit mode).

The 16- or 8-bit YCbCr data is stored in SDRAM as 4:2:2 format. [Table 8-345](#) lists the data format in SDRAM. Y data typically has a range of 16 to 235; however, it is possible to subtract a DC value from the Y signal.

Table 8-345. ISS ISP ISIF Memory Output Format for YUV Data

| Memory Address | Upper Word | | Lower Word | |
|----------------|------------|---------|------------|--------|
| | MSB(31) | LSB(16) | MSB(15) | LSB(0) |
| N | Y1 | Cr0 | Y0 | Cb0 |
| N + 1 | Y3 | Cr1 | Y2 | Cb1 |
| N + 2 | Y5 | Cr2 | Y4 | Cb2 |

8.3.3.7.18 ISS ISP ISIF Expected Bandwidth on BL Ports

The ISIF module has a write port and a read port connected to the BL. This section summarizes the expected bandwidth on these ports.

8.3.3.7.18.1 ISS ISP ISIF Write Port

The write port is used to write pixels to memory after the data have passed through the storage formatter. Data storage to SDRAM is controlled by the `ISIF_SYNCEN[1]` DWEN bit. The module allows writing the data as 16, 12, and 8 bits per pixel. The bit width is controlled by the `ISIF_CCDCFG[1:0]` SDRPACK bit field.

The write port generates a burst of 32 bytes on the MTC interface. The delay between consecutive bursts is proportional to the input pixel clock. Hence, the write port does not request peak bandwidth traffic.

[Table 8-346](#) lists the estimated delay between 32-byte MTC requests for different pixel clock frequencies and assumes the L3 clock is 200 MHz.

Table 8-346. ISP ISIF ISIF Module: Write Port Bandwidth

| Pixel Clock | Max Bandwidth 2 bytes/s pixel MB/s | Expected Delay btw MTC Requests |
|-------------|------------------------------------------|---------------------------------|
| 200 | 400 | 16 cycles = 80 ns |
| 100 | 200 | 32 cycles = 160 ns |
| 10 | 20 | 320 cycles = 1600 ns |

8.3.3.7.18.2 ISS ISP ISIF Read Port

The read port is used to read gain and offset data from SDRAM required for the LSC computation. When LSC is enabled, 8-bit gain values are read and 8-bit offset values can optionally also be read. The LSC gain computation can be enabled or disabled by setting the `ISIF_2DLSCCFG[0]` ENABLE bit. The LSC offset computation can be enabled by setting the `ISIF_2DLSCOFST[0]` OFSTEN bit.

The LSC submodule fetches four 8-bit gain values per paxel and optionally four 8-bit offset values per paxel. This is a maximum 8 bytes per paxel.

The bandwidth that is generated by the LSC module is also proportional to the paxel size. The paxel size is set up by the `ISIF_2DLSCCFG[14:12]` GAIN_MODE_M and `ISIF_2DLSCCFG[10:8]` GAIN_MODE_N bit fields. The possible values are 8, 16, 32, 64 and 128. Smaller values lead to higher memory bandwidth requirements. Hence, the worst case is achieved by setting an 8 × 8 paxel size.

When the LSC submodule is enabled it automatically prefetches two lines of gain values and two lines of offset values (if this is enabled). When the first VD comes, it again requests one line of gain values and one line of offset values (if this is enabled). Then, it again fetches one line of gain values and one line of offset values (if this is enabled) after `ISIF_2DLSCCFG[10:8] GAIN_MODE_N` lines. It continues to do so until the last row of paxels. For the last row of paxels, it fetch two lines of gain values and two lines of offset values (if this is enabled), which are used for the following frame.

By default, the LSC submodule creates peak bandwidth requirements. To avoid this, the MTC bandwidth limiter must be used to space the request over time.

The MTC bandwidth limiter must be used to smooth the bandwidth requirements of the LSC module. The MTC bandwidth limiter can be set with the `ISP5_BL_MTC_1.ISIF_R` register.

The principle is that instead of reading the gain and offset data as fast as possible, use the time that it takes for `ISIF_2DLSCCFG[10:8] GAIN_MODE_N` lines to pass through the ISP to read the data.

[Table 8-347](#) gives the estimated delay between 32-byte MTC requests for different pixel clock frequencies and assumes the L3 clock at 200 MHz.

Table 8-347. ISS ISP ISIF Read Port Bandwidth

| Pixel Clock | Max Bandwidth MB/s | Expected Delay btw MTC Requests |
|-------------|--------------------|---------------------------------|
| 200 | 25.07 | 255 cycles = 1275 ns |
| 100 | 12.5 | 510 cycles = 2550 ns |
| 10 | 1.25 | 5103 cycles = 2515 ns |

When the bandwidth limiter is used, ensure that there is enough time for the data prefetching.

- The LSC submodule must be enabled at least 2 x `ISIF_2DLSCCFG[10:8] GAIN_MODE_N` lines before the first VD.
- There must be at least `ISIF_2DLSCCFG[10:8] GAIN_MODE_N` lines of blanking. If there is not enough blanking, multiply the bandwidth requirement by 2 (that is, ensure two lines of gain and offset data can be fetched within the time of `ISIF_2DLSCCFG[10:8] GAIN_MODE_N` lines).

8.3.3.7.19 ISS ISP ISIF Events and Status Checking

The ISIF module can generate four different interrupts: VDINT0, VDINT1, VDINT2, and 2DLSCINT. The `ISIF_SYNCEN[0] SYEN` bit must be enabled to receive any of the ISIF interrupts.

8.3.3.7.19.1 ISS ISP ISIF VDINT0, VDINT1, and VDINT2 Interrupts

As shown in [Figure 8-228](#), the VDINT0, VDINT1, and VDINT2 interrupts occur relative to the VD pulse. The trigger timing is selected by using `ISIF_MODESET[2] VDPOL` bit setting. VDINT0, VDINT1, and VDINT2 occur after receiving the number of horizontal lines (HD pulse signals) set in the `ISIF_VDINT0[14:0] CDV0`, `ISIF_VDINT1[14:0] CDV1`, and `ISIF_VDINT2[14:0] CDV2` register fields, respectively.

NOTE: In the case of BT.656 input mode, there is a VD at the beginning of each field. Therefore, there are two interrupts for each frame (that is, one for each field).

If the `ISIF_MODESET[2] VDPOL` bit is set to 0, the VDINT0, VDINT1, and VDINT2 HD counters begin counting HD pulses from the rising edge of the external VD.

Figure 8-228. ISS ISP ISIF VDINT0/VDINT1/VDINT2 Interrupt Behavior When VDPOL = 0

camss-611

If the [ISIF_MODESET](#)[2] VDPOL bit is set to 1, the VDINT0, VDINT1, and VDINT2 HD counters begin counting HD pulses from the falling edge of the external VD.

Figure 8-229. ISS ISP ISIF VDINT0/VDINT1/VDINT2 Interrupt Behavior When VDPOL = 1

camss-612

8.3.3.7.19.2 ISS ISP ISIF 2DLSCINT Interrupt

See [Section 8.3.3.7.10.1.5](#) for details.

8.3.3.7.19.3 ISS ISP ISIF Status Checking

The [ISIF_MODESET](#)[15] MDFS bit is set when the field status is on an even field, and it is cleared when the field status is on an odd field.

The 2D-LSC has a register that monitors the status of the LSC. See [Section 8.3.3.7.10.1.5](#) for details.

8.3.3.8 ISS ISP BL Functional Description

8.3.3.8.1 ISS ISP BL Overview

The BL module arbitrates and merges ISP master module memory requests. The BL module also generates interrupts upon frame completion for the following modules. The interrupt generation is delayed until the actual transfer completes (ack is returned). The following interrupts are delayed by the BL module:

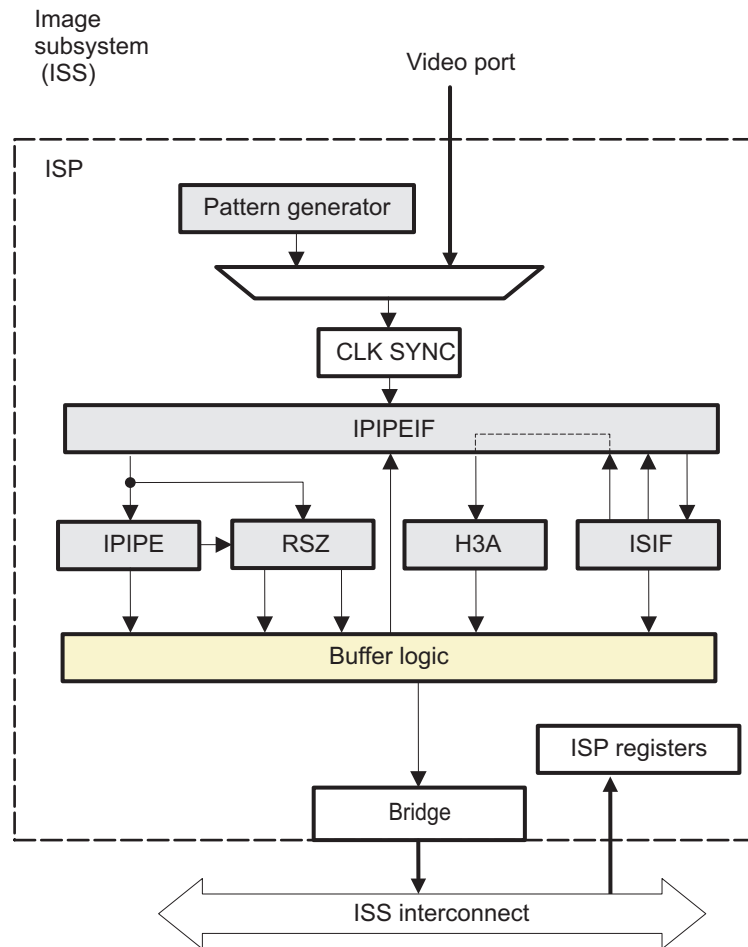

- RSZ module RSZ-A EOF
- RSZ module resizer RSZ-B EOF
- H3A module EOF
- IPIPE module EOF

The BL uses two different types of interfaces:

- MTC protocol is used between the ISP modules and the BL.
- VBUSM is use on the BL master port interface.

[Figure 8-230](#) show the BL module connections to other submodules of the ISP.

Figure 8-230. ISS ISP BL High-Level Diagram

camss-003f

8.3.3.8.2 ISS ISP BL Functional Description

The BL merges the ISP master-module memory requests to memory (read/write). The BL interfaces with all the ISP modules through a 32-bit-wide bus following.

The ISP modules make memory requests of 32 bytes. Additional signals, SOF for read and EOF for write are included to deal with boundary conditions in frame transitions.

The BL arbitration is divided into two parts: a bug hog and a fixed priority arbitration. Bus hog refers to the property of the buffer logic that gives higher priority to the module that last sent or received data. RESIZER module MTC write port 0 and RESIZER module MTC write port 1 are excluded from the bus hog.

The buffer logic is to be programmed to maximize the memory bandwidth: it makes maximum burst requests of 128 bytes (8 x 128 bits) for reads and writes. The BL can generate burst sizes of 2 x 128, 4 x 128, 6 x 128, and 8 x 128 bits.

NOTE: The ISP interface only supports burst sizes of 1, 2, 4, and 8 x 128 bits. If the BL generates a 6 x 128-bit request, it is broken into a 4 x 128-bit request, followed by another 2 x 128-bit request.

To use the memory bandwidth efficiently, the BL interfaces with the memory through a high-bandwidth bus (128 bits wide).

The BL handles memory requests for the following modules:

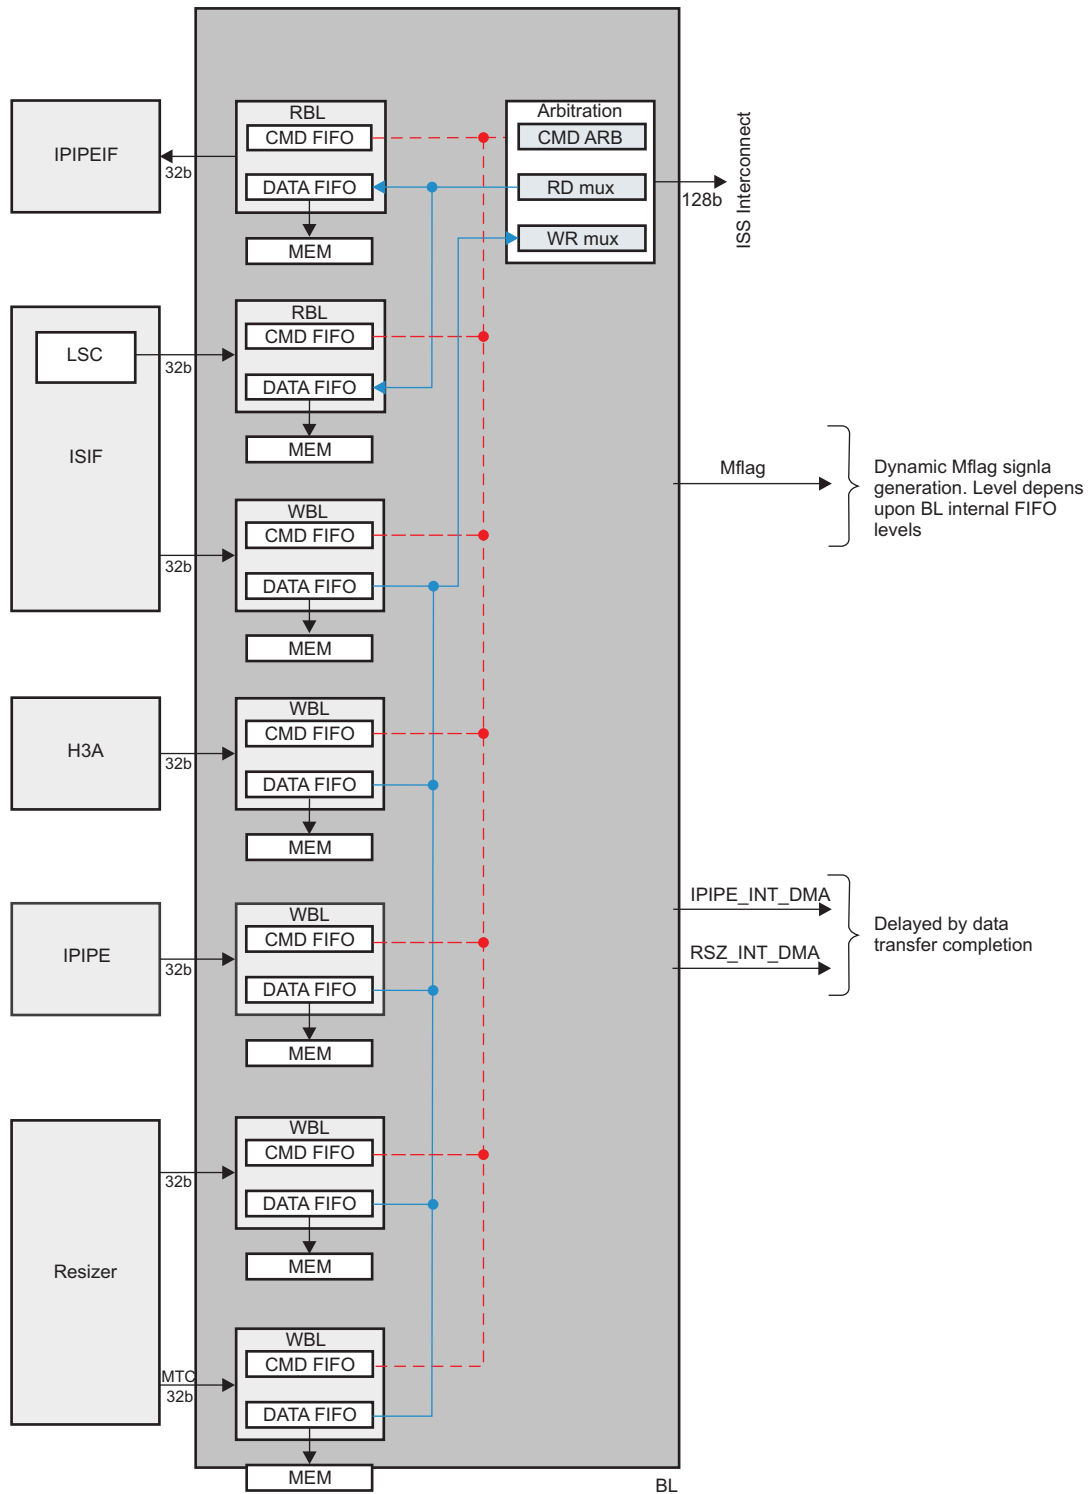

- IPIPEIF module read port
- ISIF-LSC module read port
- ISIF module write port
- IPIPE-BOXCAR module write port
- H3A module write port
- RESIZER module write port 0
- RESIZER module write port 1

From a use case point of view, the following sharing and priority arrangement is used. All reads have higher priority than writes. For reads: IPIPEIF > ISIF-LSC; for writes: ISIF > IPIPE-BOXCAR > RESIZER #0 > RESIZER #1 > H3A

NOTE: BL can generate a static or a dynamic MFlag signal. The MFlag signal is used by the ISS arbitration to consider the urgency of the requests coming from the ISP. The dynamic MFlag feature is enabled from the [ISP5_CTRL\[21\] MFLAG](#) bit.

[Figure 8-231](#) shows the BL top-level block diagram. The figure highlights the two clock domains that are used.

Figure 8-231. ISS ISP BL Block Diagram

camss-080u

NOTE: The BL module has no registers. The configurations come from the top level of the ISP. See [Table 8-389](#) for register details.

8.3.3.8.3 ISS ISP BL Address Alignment

The BL module ensures maximum memory efficiency by re-aligning data to a 128-byte address boundary. In all cases, the BL accesses are 32-byte-aligned: address [4:0] is always 0.

This is required when the input address is a multiple of 32 bytes, not 128 bytes. The BL issues a non-aligned burst until it reaches a 128-byte boundary, and then keeps making a 128-byte request until the end of the line. Eventually, although the last burst in a line may not be a multiple of 128 bytes, it will always be a multiple of 32 bytes, as shown in [Figure 8-232](#).

Figure 8-232. ISS ISP BL Address Alignment

camss-687

8.3.3.8.4 ISS ISP BL Out-of-Order Responses

BL supports out-of-order responses. The out-of-order response is handled by having up to 16 outstanding CIDs (reads + writes). The maximum number of outstanding CIDs is set up by the `ISP5_CTRL[7:4]` `VBUSM_CIDS` bit field. There is one outstanding request per CID.

If any of the CIDs are not outstanding, a command is accepted from the highest prioritized buffer with a request. The CID availability is cleared when status complete is received. The outstanding commands can be all reads or all writes or any combination. The CID that is allocated is the lowest number of the 16 that are available when the command is accepted. As soon as a CID is released it is used if a command is available.

The `VBUSM2OCP` module transforms the `VBUSM` CIDs into `OCP MFlag` signals. Note that there can be only one outstanding per tag. It is not authorized to make a new request on a tag which is already waiting for a response.

8.3.3.8.5 ISS ISP BL Stalling

The BL can stall the requests from the initiator modules for reads and writes

8.3.3.8.5.1 ISS ISP BL Stalling Write Requests

One reason for the BL to stall write requests is that usually there is back pressure on the system memory and requests cannot be issued as fast as required. In that case the BL needs to stall requests from the initiator modules. The BL module cannot know whether the request stalling will lead to an initiator overflow or not. The `RESIZER` module can support back pressure from the BL module when it is configured in bypass mode. The input buffer memory can be used to store data from the `IPIPE` and `IPIPEIF` modules. If the `RESIZER` input buffer overflows, an interrupt is issued.

8.3.3.8.5.2 ISS ISP BL Stalling Read Requests

The BL may also stall read requests from the `ISIF-LSC` and `IPIPEIF` modules. When data is coming from an image sensor there is no way to stop the sensor. If the read request is stalled too long, the `LSC` module may eventually underflow. When the `IPIPEIF` module reads all its data from memory, the `IPIPEIF` stalls transfers to successive modules by masking the clock.

8.3.3.8.6 ISS ISP BL Dynamic and Static MFlag Generation

NOTE: The following applies when the `ISP5_CTRL[21] MFLAG = 1`. The MFlag value is static.

The BL outputs `cpriority[2:0]` and `cepriority[2:0]` signals on its VBUS master port interface. On the VBUSM side, these signals are aligned with the request (`creq`). Both values are actually repeating register input signals. The lower value (0) corresponds to the higher priority.

The MFlag signal does not need to be aligned with the request. The signal can change value anytime.

In the ISP VBUSM2 interface bridge, the `cepriority` signal is ignored and only the `cpriority` signal is used. Because the priority value is set up by a register setting, the value is not going to be dynamically modified obviously. [Table 8-348](#) shows how the `cpriority` values are mapped to the interface MFlag signal, which is present on the ISP master interface and set in the `ISP5_CTRL[3:1] VBUSM_CPRIORITY` bit field.

Table 8-348. ISS ISP BL `cpriority` to MFlag With `ISP5_CTRL[21] MFLAG = 1`

| MFlag[1:0] | Description |
|------------|----------------------------------------------------------|
| 00 | Normal priority <code>cpriority[2:0] = 4, 5, 6, 7</code> |
| 01 | Medium priority <code>cpriority[2:0] = 2, 3</code> |
| 10 | Reserved |
| 11 | High priority <code>cpriority[2:0] = 0, 1</code> |

NOTE: The following applies when the `ISP5_CTRL[21] MFLAG = 0`. The MFlag value is dynamic.

This feature is enabled at reset. The general idea for the dynamic MFlag generation is to monitor the FIFO levels. Thresholds are used to increase or decrease the MFlag values. There are different implementations for read and write requestors.

An individual MFlag value is generated for each FIFO and then ORed altogether and exported at the BL boundary. The MFlag signal generation does not affect the BL arbitration scheme.

- Writes: To prevent overflows in the BL, the dynamic MFlag signal generation gives higher priority to FIFOs that are almost full:
 - Low FIFO level = 50%
 - High FIFO level = 75%
 - FIFOs with more than 75% fill level have high priority: MFlag = 11
 - FIFOs between 50 and 75% fill level have medium priority: MFlag = 01
 - FIFOs below 50% fill level have normal priority: MFlag = 00

[Table 8-349](#) gives the low- and high-level priority thresholds for write initiators.

Table 8-349. ISS ISP BL MFlag Write Low- and High-Level Priority Thresholds

| | ISIF | H3A | IPIPE | RSZ |
|----------------|----------|----------|----------|----------|
| Access type | Write | Write | Write | Write |
| Buffer size | 64 × 128 | 64 × 128 | 48 × 128 | 64 × 136 |
| 50% low level | 32 × 128 | 32 × 128 | 24 × 128 | 32 × 136 |
| 75% high level | 48 × 128 | 48 × 128 | 36 × 128 | 48 × 128 |

- Reads: The dynamic MFlag signal generation depends on the "reserved data units" in the initiator data FIFO. The reserved data units correspond to read commands waiting to be sent on the interface bus plus the read commands that have been sent on the interface bus and for which data responses have not yet arrived.
- The total FIFO size in bytes can be expressed as reserved data units (bytes) + data bytes stored (bytes) + empty space (bytes). By definition, empty space is lower than a burst size (128 bytes).
 - Low FIFO level = 25%

- High FIFO level = 50%
- Data bytes stored + empty space (bytes) = 50% of FIFO size: MFlag = 00
- Data bytes stored + empty space (bytes) 50% of FIFO size: MFlag = 01
- Data bytes stored + empty space (bytes) 25% of FIFO size: MFlag = 11

Table 8-350 gives the low- and high-level priority thresholds for read initiators

Table 8-350. ISS ISP BL MFlag Read Low- and High-Level Priority Thresholds

| | IPIPEIF | ISIF-LSC |
|-----------------|----------|----------|
| Access type | Read | Read |
| Buffer size | 64 x 128 | 32 x 128 |
| 25% buffer size | 16 x 128 | 8 x 128 |
| 50% buffer size | 32 x 128 | 16 x 128 |

8.3.3.8.7 ISS ISP BL VBUSM2OCP Last Beat Command Delay

The VBUSM2OCP module bridge implements the following function to work around a limitation of the BL module, which does not send back-to-back requests to the ISS, thereby leading to possible situations where the ISP loses arbitration at the ISS level.

To fully benefit from the dynamic MFlag generation (see Section 8.3.3.8.6), the following function is present in the VBUSM2OCP module bridge:

- The delay occurs only if BL MFlag = `ISP5_BL_VBUSM[5] MFLAG_THRES`.
- The MFlag value used is whatever is available when the last beat comes on the interface bus.
- The last beat of the interface request (read or write) is held until one cycle before a new command (read or write). This is achieved by masking the last beat of the interface command at the ISP interface.

The last beat is unmasked on the first event of (i) one cycle before a new interface command, or (ii) the delay counter that uses the `ISP5_BL_VBUSM[4:0] LASTCMD_DLY` value counter expires (has decremented to zero). The `ISP5_BL_VBUSM[4:0] LASTCMD_DLY` bit field must be set before the request on the BL starts. If the value of the `ISP5_BL_VBUSM[4:0] LASTCMD_DLY` bit field is changed during the pending requests, the delay counter is not updated.

8.3.3.8.8 ISS ISP BL Peak Memory Bandwidth Reduction

To limit the peak memory bandwidth generated by the IPIPEIF (read port), ISIF (read port), and H3A (write port) modules, a bandwidth limiter is placed between the modules and the BL. The resizer module has this function built in and therefore does not need a bandwidth limiter.

The bandwidth limiter enables control of the minimum interval between two consecutive memory requests.

This function is controlled by the `ISP5_BL_MTC_1` and `ISP5_BL_MTC_2` registers. When the registers are set to 0, the function is not modified (that is, the bandwidth limiter is disabled). For the resizer module, it is controlled by the following registers: `RSZ_DMA_RZA` and `RSZ_DMA_RZB`.

8.3.3.9 ISS ISP Memory Mapping

A total of 64KB is reserved for the ISP registers and memories. Table 8-351 describes the memory map.

Table 8-351. ISS ISP Memory Mapping

| Memory Mapping | Start | End | Size | Comments |
|-----------------------|-------------|-------------|------|--------------------------------------|

8.3.4 ISS ISP Programming Model

NOTE: The preferred way to perform memory-to-memory processing with ISP is to use the CCP2 receiver module at the ISS level (see [Section 8.2 ISS Interfaces](#)). It is possible to use the IPIPEIF read port for memory-to-memory processing, but it is not the preferred way because it does not provide enough granularity on the fractional clock divider for up to 20x digital zoom.

8.3.4.1 ISS ISP PG Programming Model

The procedure in [Table 8-352](#) initializes the pattern generator.

Table 8-352. ISS ISP PG Settings

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------------------------------|--------------------------------------|-------|
| Select the PG as the ISP source. | ISP5_PG[5:4] SRC_SEL | 0x3 |
| Select the mode for write-enable signal generation. | ISP5_PG[2] WEN | |
| Select the polarity of the horizontal sync signal. | ISP5_PG[1] HDPOL | |
| Select the polarity of the vertical sync signal. | ISP5_PG[0] VDPOL | |
| Sets the duration of the HD signal | ISP5_PG_PULSE_CTRL[12:0] HDW | |
| Sets the duration of the VD signal | ISP5_PG_PULSE_CTRL[27:16] VDW | |
| Sets the number of pixels per line | ISP5_PG_FRAME_SIZE[31:16] PPLN | |
| Sets the number of lines per frame | ISP5_PG_FRAME_SIZE[15:0] HLPFR | |
| Enables the pattern generator | ISP5_PG[3] EN | 0x1 |

8.3.4.2 ISS ISP ISIF Programming Model

This section discusses issues related to the software control of the ISIF. It lists the registers that are required to be programmed in different modes, describes how to enable and disable the ISIF and how to check the status of the ISIF, discusses the different register access types, and enumerates several programming constraints.

8.3.4.2.1 ISS ISP ISIF Hardware Setup/Initialization

This section discusses the configuration of the ISIF required before image processing can begin.

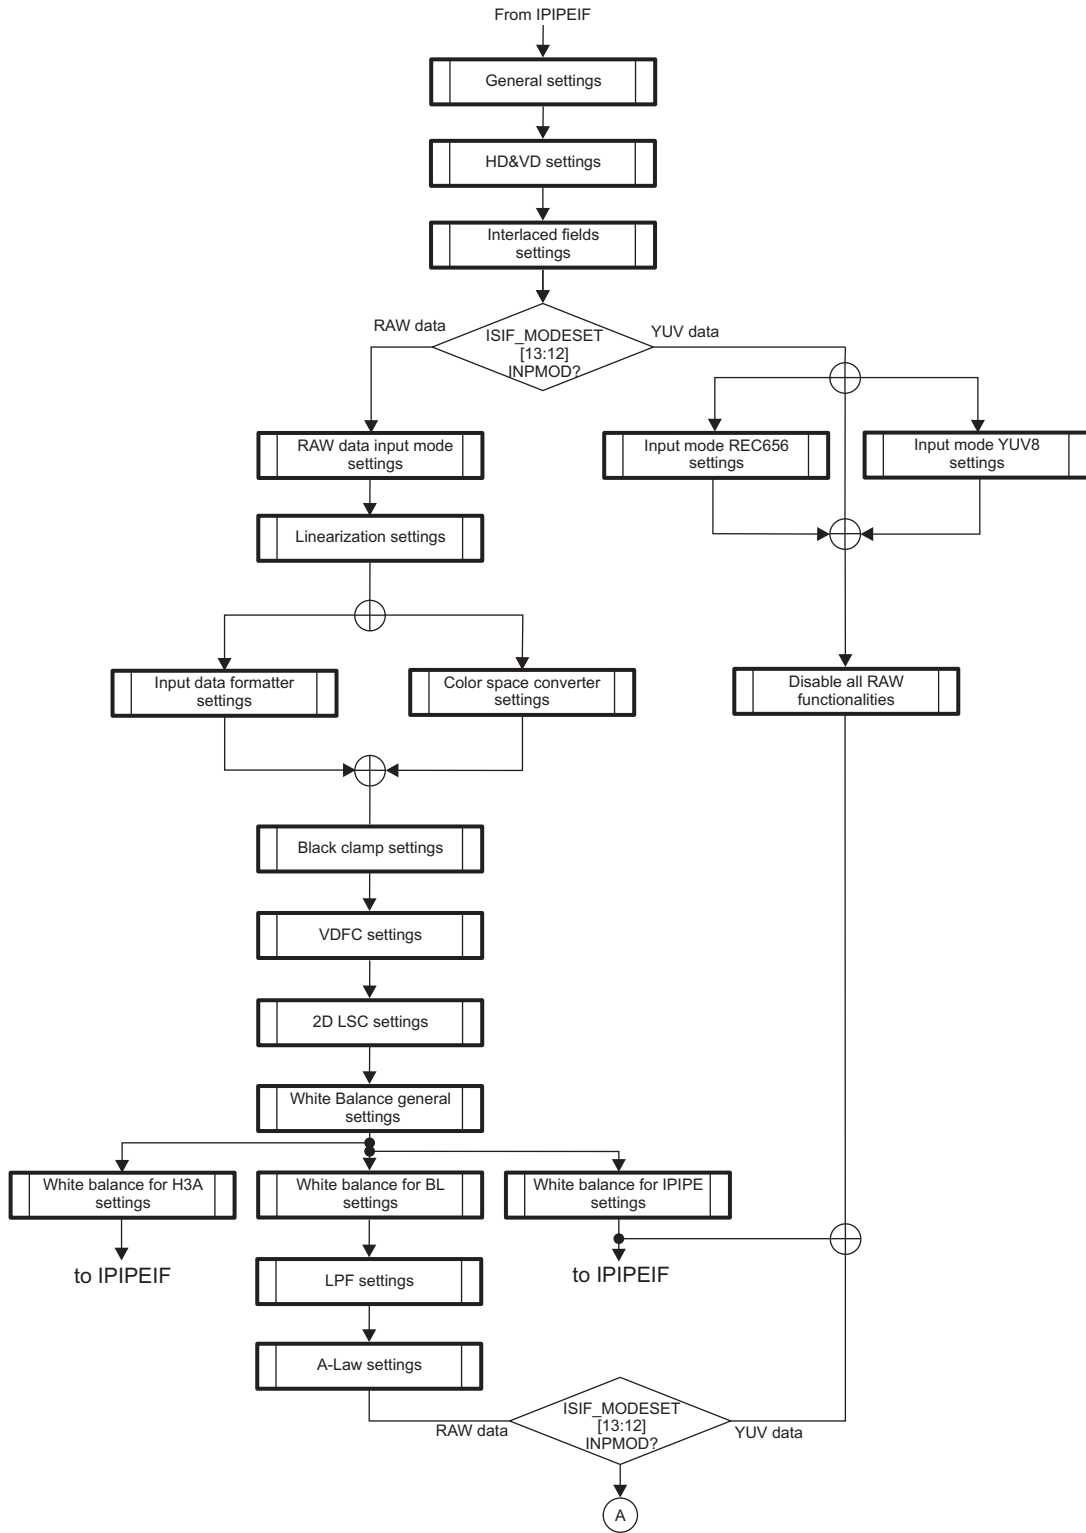

8.3.4.2.1.1 ISS ISP ISIF Reset Behavior

Upon hardware reset of the ISP, all of the registers in the ISIF are reset to their reset values except the defect table registers. Because the defect table registers are stored in internal RAM, they do not have reset values. If the reset is a chip-level POR (reset after power is applied), the defect table register values are unknown. If the reset is an ISP module reset (when power remains active), the contents of this memory remain the same as before the reset.

8.3.4.2.1.2 ISS ISP ISIF Register Setup

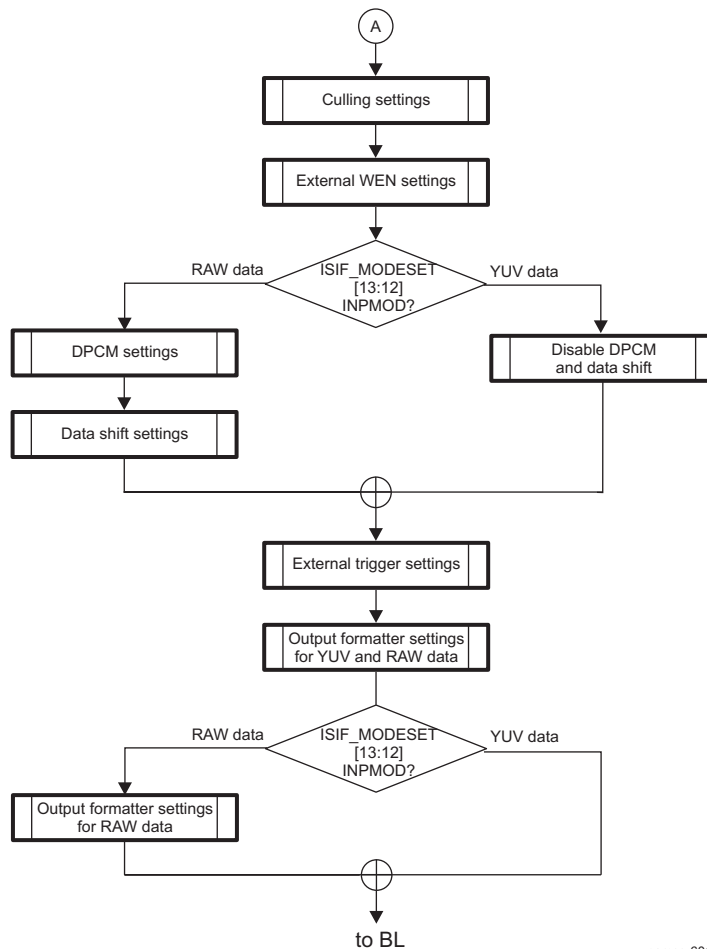

Before enabling the ISIF, the hardware must be properly configured through register writes. [Figure 8-233](#) and [Figure 8-234](#) show the sequence to be used for RAW and YUV data before enabling the ISIF. The register settings for each process in the following sequence are described in [Table 8-353](#).

| Enable or disable the storage of image in memory. | ISIF_SYNCEN[1] DWEN | |
| Set the memory destination address. | ISIF_CADU[10:0] CADU ISIF_CADL[10:0] CADL | |
| Enable or disable MSB inverse of COUT port. | ISIF_CCDCFG[14] MSBINVO | |
| Enable or disable byte swap when SDRAM capturing. | ISIF_CCDCFG[12] BSWD | |
| Select Y and C swapping. | ISIF_CCDCFG[2] YCOUNTSWP | |
| Select SDRAM pack mode. | ISIF_CCDCFG[1:0] SDRPACK | |
| Enable or disable VD/HD output. | ISIF_SYNCEN[0] SYEN | |

8.3.4.2.2 ISS ISP ISIF Enable/Disable Hardware

The ISIF is enabled by setting the ISIF_SYNCEN[0] SYEN bit. This should be done after all the required registers discussed in the previous section are programmed.

With respect to the write enable bit and output address, the following procedure must be followed:

1. Set the data output address (ISIF_CADU and ISIF_CADL).
2. Enable HD/VD and WEN at the same time (ISIF_MODESET[1] DWEN and ISIF_SYNCEN[0] SYEN).

If the ISIF_SYNCEN[0] SYEN bit is written before the output address and the SDRAM write enable bit (not recommended but may be required for a particular mode), data begins to be written to the old address value and not the one recently programmed. The desired response can be achieved if the following procedure is followed:

1. Enable HD/VD (ISIF_SYNCEN[0] SYEN).
2. Set the output address (ISIF_CADU and ISIF_CADL).
3. Wait for the next VD.
4. Enable WEN (ISIF_MODESET[1] DWEN).

The ISIF always operates in continuous mode. In other words, after enabling the ISIF, it continues to process sequential frames until the ISIF_SYNCEN[0] SYEN bit is cleared by software. When this happens, the frame being processed is disabled immediately, and does not continue to process the current frame.

When the HD/VD signals are set to outputs ([ISIF_MODESET\[0\]](#) HDVDD = 0x1), fetching and processing of the frame begin immediately upon setting the [ISIF_SYNCEN\[0\]](#) SYEN bit.

When the HD/VD signals are set to inputs ([ISIF_MODESET\[0\]](#) HDVDD = 0x0), processing of the frame is dependent on the input timing of the external sensor/decoder. To ensure that data from the external device is not missed, the ISIF must be enabled before data transmission from the external device. In this way, the ISIF waits for data from the external device.

8.3.4.2.3 ISS ISP ISIF Register Accessibility During Frame Processing

There are two types of register access in the ISIF:

- Shadowed registers (event latched registers)
Shadowed registers are those that can be read and written at any time, but the written values take effect (are latched) only at certain times based on some event. Reads still return the most recent write even though the settings are not used until the specific event occurs.
- Busy-writable registers
These registers/fields can be read or written even if the module is busy. Changes to the underlying settings takes place instantly.

The following registers/fields can all be set as shadow registers, or optionally set as busy-writable registers. When the [ISIF_CCDCFG\[15\]](#) VDLC bit is set to 0, these registers are shadowed; when the [ISIF_CCDCFG\[15\]](#) VDLC bit is set to 1, these registers are busy-writable. All other ISIF registers not included in this list are always busy-writable.

| | | | |
|---------------------------------------|-----------------------------|------------------------------------------|-------------------------------|
| ISIF_SYNCEN[1] DWEN | ISIF_SLV1 | ISIF_CGRGAIN | ISIF_FMTLSV |
| ISIF_MODESET[14] HLPF | ISIF_CULH | ISIF_CGBGAIN | ISIF_FMTLNV |
| ISIF_HDW | ISIF_CULV | ISIF_CBGAIN | ISIF_LSCHOFST |

| ISIF_PPLN | ISIF_SDOFST | ISIF_CLAMPCFG[0] CLEN | ISIF_DFCCTL |
| ISIF_LPFR | ISIF_CADU | ISIF_MISC | ISIF_VDFSATLV |
| ISIF_SPH | ISIF_CADL | ISIF_CGAMMAWD | |
| ISIF_LNH | ISIF_CCOLP | ISIF_FMTSPH | |
| ISIF_SLV0 | ISIF_CRGAIN | ISIF_FMTLNH | |

8.3.4.2.4 ISS ISP ISIF Interframe Operations

Between frames, it may be necessary to enable or disable functions or to modify the memory pointers. Because the [ISIF_SYNCEN\[1\]](#) DWEN bit and the memory pointer registers are shadowed, these modifications can occur any time before the end of the frame and the data will be latched in for the next frame. Likewise, the 2D-LSC registers can be changed after receiving the LSC SOF interrupt but before it starts to prefetch the gain values for the next frame (the end of the LSC active region is reached). The host controller can perform these changes upon receiving an interrupt.

8.3.4.2.5 ISS ISP ISIF Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the ISIF. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- PCLK cannot be higher than 200 MHz.
- If SDRAM output port is enabled:
 - The memory output line offset and address must be on 32-byte boundaries.
 - [ISIF_LNH\[14:0\]](#) LNH -1 must be a multiple of 32 bytes.
 - [ISIF_SPH](#), [ISIF_LNH](#), [ISIF_SLV0](#), [ISIF_SLV1](#), and [ISIF_LNV](#) must be cleared to 0 within the same VD period that the [ISIF_SYNCEN\[1\]](#) DWEN bit is cleared to 0.

- [ISIF_SPH](#), [ISIF_LNH](#), [ISIF_SLV0](#), [ISIF_SLV1](#), and [ISIF_LNV](#) must be set from 0 to the appropriate values within the same VD period that the [ISIF_SYNCEN\[1\]](#) DWEN bit is set to 1.
- In RAW input mode:
 - [ISIF_CCDCFG\[4\]](#) YCINSWP must be set to 0.
- If DPCM compression is enabled:
 - Horizontal culling must not be used. Use the input formatter instead.
- For 2D-LSC:
 - $N \leq M$ (where M = horizontal downsampling factor, N = vertical downsampling factor)
 - The [ISIF_2DLSCINI](#) register values must be even numbers.
 - Maximum widths with respect to selected M value (see [Table 8-354](#))

Table 8-354. ISS ISP ISIF Maximum Line Width Versus M Value

| M | Maximum Line Width |
|-----|--------------------|
| 8 | 2040 |
| 16 | 4080 |
| 32 | 8160 |
| 64 | 16,320 |
| 128 | 16,384 |

8.3.4.3 ISS ISP IPIPEIF Programming Model

This section discusses issues related to the software control of the IPIPEIF module. It lists the registers that are required to be programmed in different modes, describes how to enable and disable the IPIPEIF module and how to check the status of the IPIPEIF module, discusses the different register access types, and enumerates several programming constraints.

8.3.4.3.1 ISS ISP IPIPEIF Hardware Setup/Initialization

This section discusses the configuration of the IPIPEIF module required before image processing can begin.

8.3.4.3.1.1 ISS ISP IPIPEIF Reset Behavior

Upon hardware reset of the ISP ([ISP5_SYSCONFIG\[1\]](#) SOFTRESET = 0x1), all of the registers in the IPIPEIF are reset to their reset values.

8.3.4.3.1.2 ISS ISP IPIPEIF Register Setup

Before enabling the IPIPEIF, the hardware must be properly configured through register writes. [Table 8-355](#) identifies the register parameters that must be programmed before enabling the IPIPEIF module (depending on the functions needed).

Table 8-355. ISS ISP IPIPEIF Required Configuration Parameters

| Step | Configuration Required | Value |
|---------------------------------------|------------------------------------------------------------------------------------------|-------|
| General settings | | |
| Select the input sources for IPIPEIF. | IPIPEIF_CFG1[15:14] INPSRC1 IPIPEIF_CFG1[3:2] INPSRC2 | |
| Select VD sync polarity. | IPIPEIF_CFG2[2] VDPOL | |
| Select HD sync polarity. | IPIPEIF_CFG2[1] HDPOL | |
| Select the interrupt source. | IPIPEIF_CFG2[0] INTSW | |
| Select the input clock source. | IPIPEIF_CFG1[10] CLKSEL | |
| Set the clock divider value. | IPIPEIF_CLKDIV[15:0] CLKDIV | |
| Set the data type: YUV or RAW. | IPIPEIF_CFG2[3] YUV16 | |

Table 8-355. ISS ISP IPIPEIF Required Configuration Parameters (continued)

| Step | Configuration Required | Value |
|-------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|-------|
| Settings to perform if data is from BL | | |
| Set HD setting. | IPIPEIF_PPLN[12:0] PPLN | |
| Set VD setting. | IPIPEIF_LPFR[12:0] LPFR | |
| Set the number of valid pixels in a line. | IPIPEIF_HNUM[12:0] HNUM | |
| Set the number of valid lines. | IPIPEIF_VNUM[12:0] VNUM | |
| Set memory address information. | IPIPEIF_ADDRU[10:0] ADDRU IPIPEIF_ADDRL[15:0] ADDRL IPIPEIF_ADOFS[11:0] ADOFS | |
| Set one-shot mode, if needed. | IPIPEIF_CFG1[0] ONESHOT | |
| Use SYNCOFF function only for double-buffering. See Section 8.3.3.3.3.2.1 for details. | IPIPEIF_ENABLE[1] SYNCOFF | |
| Settings to perform for RAW data from ISIF or BL | | |
| Select the unpack function. | IPIPEIF_CFG1[9:8] UNPACK | |
| Settings to perform for YUV for data from ISIF | | |
| Set the data type to YUV. | IPIPEIF_CFG2[3] YUV16 | |
| If YUV16 = 0x1, enables or not the conversion from 8 bits to 16 bits | IPIPEIF_CFG2[6] YUV8 | |
| If YUV16 = 0x1, set the way the data is unpacked. | IPIPEIF_CFG2[7] YUV8P | |
| DCPM function | | |
| Enable or disable DPCM decompression. | IPIPEIF_DPCM[0] ENA | |
| Select DPCM prediction mode. | IPIPEIF_DPCM[1] PRED | |
| Select DPCM bit mode. | IPIPEIF_DPCM[2] BITS | |
| Select inverse A-Law function. | IPIPEIF_CFG1[9:8] UNPACK | |
| Select SDRAM read data shift. - For RAW data - DPCM enabled and A- Law disabled - or DPCM disabled | IPIPEIF_CFG1[13:11] DATASFT | |
| Dark frame subtraction (DFS) function | | |
| Set defect pixel correction (DPC1) for VP or ISIF inputs. | RAW data from VP (video port), BL(buffer logic, SDRAM) or ISIF | |
| Set the associated threshold for DPC1. | IPIPEIF_DPC1[12] ENA | |
| Set defect pixel correction (DPC2) for BL inputs. | IPIPEIF_DPC1[11:0] TH | |
| Set the associated threshold for DPC2. | IPIPEIF_DPC2[12] ENA | |
| Set the associated threshold for DPC1. | IPIPEIF_DPC2[11:0] TH | |
| Set the direction of subtraction. | IPIPEIF_CFG2[5] DFSDIR | |
| Set the averaging filter, horizontal pixel decimator, and gain function for IPIPE data path. | | |
| Enable averaging filter function. | IPIPEIF_CFG1[7] AVGFILT | |
| Enable horizontal pixel decimation function. | IPIPEIF_CFG1[1] DECIM | |
| Set horizontal resizing value. | IPIPEIF_RSZ[6:0] RSZ | |
| Set the resizer initial position. | IPIPEIF_INIRSZ[13] ALNSYNC IPIPEIF_INIRSZ[12:0] INIRSZ | |
| Set the data gain (only for RAW data). | IPIPEIF_GAIN[9:0] GAIN | |
| Set the output clipping value. | IPIPEIF_OCLIP[11:0] OCLIP | |

Table 8-355. ISS ISP IPIPEIF Required Configuration Parameters (continued)

| Step | Configuration Required | Value |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------|-------|
| Set the averaging filter and horizontal pixel decimator function for H3A data path. | | |
| Enable averaging filter function. | IPIPEIF_RSZ3A[8] AVGFILT | |
| Enable horizontal pixel decimation function. | IPIPEIF_RSZ3A[9] DECIM | |
| Set horizontal resizing value. | IPIPEIF_RSZ3A[6:0] RSZ | |
| Set the resizer initial position. | IPIPEIF_RSZ3A[13] ALNSYNC IPIPEIF_RSZ3A[12:0] INIRSZ | |

For information about YUV data coming and unpacking from the ISIF module, see [Section 8.3.3.3.13](#).

8.3.4.3.2 ISS ISP IPIPEIF Enable/Disable Hardware

When [IPIPEIF_CFG1\[15:14\]](#) INPSRC1 or [IPIPEIF_CFG1\[3:2\]](#) INPSRC2 = 0, the IPIPEIF does not need to be enabled: it receives data from the VP and pushes it to the ISIF, H3A, IPIPE, and RESIZER modules.

If [IPIPEIF_CFG1\[15:14\]](#) INPSRC1 or [IPIPEIF_CFG1\[3:2\]](#) INPSRC2 ≠ 0, the IPIPEIF module begins to fetch data from the BL by setting the [IPIPEIF_ENABLE\[0\]](#) ENABLE bit. Writing the enable bit must be the last step of the configuration.

When the input source is the BL, the IPIPEIF can optionally operate in one-shot mode or continuous mode by setting the [IPIPEIF_CFG1\[0\]](#) ONESHOT parameter. If one-shot mode is enabled, then after enabling the IPIPEIF, the [IPIPEIF_ENABLE\[0\]](#) ENABLE bit is automatically turned off (set to 0) and only a single frame is processed from memory. In this mode, fetching and processing of the frame begins immediately upon setting the [IPIPEIF_ENABLE\[0\]](#) ENABLE bit.

When the input source is the ISIF, processing of the frame is dependent on the timing of the ISIF. To ensure that data from the ISIF is not missed, the IPIPEIF must be enabled before the ISIF. In this way, the IPIPEIF waits for data from the ISIF.

When the IPIPEIF is in continuous mode, it can be disabled by clearing the [IPIPEIF_ENABLE\[0\]](#) ENABLE bit after processing of the last frame. The disable takes place immediately because it is a busy-writable register.

An EOF interrupt can indicate to other modules that the frame treatment is finished. See [Section 8.3.3.3.15](#) for details.

8.3.4.3.3 ISS ISP IPIPEIF Register Accessibility During Frame Processing

There are two types of register access in the IPIPEIF:

- Shadow registers

These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame (VD rising edge). Reads still return the most recent write even though the settings are not used until the next start of frame. The following are the shadowed registers in the IPIPEIF.

| | | |
|----------------------------------------|-------------------------------------------|------------------------------------------|
| IPIPEIF_PPLN | IPIPEIF_ADDRU | IPIPEIF_CFG1[1] DECIM |
| IPIPEIF_HNUM | IPIPEIF_ADOFS | IPIPEIF_CFG1[7] AVGFILT |
| IPIPEIF_VNUM | IPIPEIF_ENABLE[1] SYNCOFF | IPIPEIF_RSZ |
| IPIPEIF_GAIN | IPIPEIF_RSZ3A[9] DECIM | IPIPEIF_RSZ3A[8] AVGFILT |
| IPIPEIF_RSZ3A[6:0] RSZ | | |

- Busy-writeable registers

These registers/fields can be read or written even if the module is busy. Changes to the underlying settings takes place instantaneously. Registers that are not shadowed are busy-writeable.

Only for busy-writeable registers, the ideal procedure for changing the IPIPEIF registers is IF (PCR.BUSY == 0) OR IF (EOF interrupt occurs):

- Disable IPIPEIF ([IPIPEIF_ENABLE\[0\]](#) ENABLE = 0x0).
- Change registers.
- Enable IPIPEIF ([IPIPEIF_ENABLE\[0\]](#) ENABLE = 0x1).

8.3.4.3.4 ISS ISP IPIPEIF Interframe Operations

Between frames, it may be necessary to enable or disable functions or to modify the memory pointers. Because several of the registers are shadowed, these modifications can take place any time before the end of the frame, and the data is latched in for the next frame. The host controller can perform these changes upon receiving an interrupt.

When reading input data from the BL, the host must check [IPIPEIF_DTUF](#) or the [ISP5_IRQSTATUS_RAW2_i\[1\]](#) [IPIPEIF_UDF](#) register (if this event is enabled and mapped to the ISP IRQ lines) during vertical blanking to see if an underflow occurred.

If an underflow occurs it means the system is congested because too much bandwidth is being generated. It is most likely that the scenario being passed is too memory bandwidth-intensive. If the bit is set, software must clear the bit. If the process is taking place from memory-to-memory, the software may try to re-initiate the data flow. Software must decide the sequence to execute after an underflow.

8.3.4.3.5 ISS ISP IPIPEIF Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the IPIPEIF module. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- If BL is the source for the IPIPEIF:
 - The memory output line offset and address must be on 32-byte boundaries.
 - In DFS block, [IPIPEIF_LPFR](#) must be > 0, because the first line cannot be fetched.
 - [IPIPEIF_PPLN](#) > [IPIPEIF_HNUM](#)
 - [IPIPEIF_LPFR](#) > [IPIPEIF_VNUM](#) + 1
- There are restrictions on [IPIPEIF_CFG1\[15:14\]](#) INPSRC1 and [IPIPEIF_CFG1\[3:2\]](#) INPSRC2 combinations. See [Table 8-310](#) for details.

8.3.4.4 ISS ISP IPIPE Programming Model

This section covers the low-level hardware programming sequences for the configuration and use of the ISS PIPE module.

8.3.4.4.1 Global Initialization

8.3.4.4.1.1 Surrounding Modules Global Initialization

This initialization of surrounding modules is based on the integration of the ISS ISP.

8.3.4.4.1.2 ISS IPIPE Global Initialization

8.3.4.4.1.2.1 Main Sequence – ISS ISP IPIPE Global Initialization

This procedure initializes the ISS ISP PIPE modules after a POR or software reset.

Table 8-356. ISS Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------------------------------------------|--------------------------------------|-------|
| Set the IPIPE processing modes. | IPIPE_SRC_MODE[0] OST | 0x- |
| Select the IPIPEIF module as a source. | IPIPE_SRC_MODE[1] WRT | 0x1 |
| Set the vertical start position of the window to process. | IPIPE_SRC_VPS[15:0] VAL | 0x- |
| Set the horizontal start position of the window to process. | IPIPE_SRC_HPS[15:0] VAL | 0x- |
| Set the vertical size of the processing area. | IPIPE_SRC_VSZ[12:0] VAL | 0X- |
| Set the horizontal size of the processing area. | IPIPE_SRC_HSZ[12:1] VAL | 0x- |
| Enable clk_arm_g0. | IPIPE_GCK_MMR[0] REG | 0x- |
| Enable the clk_pix_g3. | IPIPE_GCK_PIX[3] G3 | 0x- |
| Enable the clk_pix_g2. | IPIPE_GCK_PIX[2] G2 | 0x- |
| Enable the clk_pix_g1. | IPIPE_GCK_PIX[1] G1 | 0x- |
| Enable the clk_pix_g0. | IPIPE_GCK_PIX[0] G0 | 0x- |
| Enable IPIPE module. | IPIPE_SRC_EN[0] EN | 0x1 |

8.3.4.4.1.2.2 Subsequence – ISS ISP IPIPE Defect Pixel Correction Initialization

8.3.4.4.1.2.2.1 Subsequence – ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

Table 8-357. ISS ISP IPIPE LUT Defect Pixel Correction (LUT DPC)

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------------------------------|--------------------------------------|-------|
| Set the address of the first valid data in the LUT. | IPIPE_DPC_LUT_ADR[9:0] ADR | 0x- |
| Set the LUT type. | IPIPE_DPC_LUT_SEL[1] TBL | 0x- |
| Set the size of the LUT. | IPIPE_DPC_LUT_SIZ[9:0] SIZ | 0x- |
| Set the dot replacement correction method . | IPIPE_DPC_LUT_SEL[0] DOT | 0x- |
| Enable LUT DPC. | IPIPE_DPC_LUT_EN[0] EN | 0x1 |

8.3.4.4.1.2.3 Subsequence – ISS ISP IPIPE White Balance Initialization

Table 8-358. ISS ISP IPIPE White Balance Initialization

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------|-------|
| Set the offset before white balance. | IPIPE_WB2_OFT_R[11:0] VAL IPIPE_WB2_OFT_GR[11:0] VAL IPIPE_WB2_OFT_GB[11:0] VAL IPIPE_WB2_OFT_B[11:0] VAL | 0x- |
| Set the white balance gain. | IPIPE_WB2_WGN_R[12:0] VAL IPIPE_WB2_WGN_GR[12:0] VAL IPIPE_WB2_WGN_GB[12:0] VAL IPIPE_WB2_WGN_B[12:0] VAL | 0x- |

8.3.4.4.1.2.4 Subsequence - ISS ISP IPIPE RGB2RGB Blending Module Initialization

Table 8-359. ISS ISP IPIPE RGB2RGB Blending Module Initialization

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| Set gain range. | IPIPE_RGB1_MUL_RR[11:0] VAL IPIPE_RGB1_MUL_GR[11:0] VAL IPIPE_RGB1_MUL_BR[11:0] VAL IPIPE_RGB1_MUL_RG[11:0] VAL IPIPE_RGB1_MUL_GG[11:0] VAL IPIPE_RGB1_MUL_BG[11:0] VAL IPIPE_RGB1_MUL_RB[11:0] VAL IPIPE_RGB1_MUL_GB[11:0] VAL IPIPE_RGB1_MUL_BB[11:0] VAL | 0x- |
| Se the offset range for each component. | IPIPE_RGB1_OFT_OR[12:0] VAL IPIPE_RGB1_OFT_OG[12:0] VAL IPIPE_RGB1_OFT_OB[12:0] VAL | 0x- |

8.3.4.4.1.2.5 Subsequence – ISS ISP IPIPE Gamma Correction Module Initialization

Table 8-360. ISS ISP IPIPE Gamma Correction Module Initialization

| Step | Register/Bit Field/Programming Model | Value |
|----------------------------------------------|-------------------------------------------------------------------------|-------|
| Select the gamma table. | IPIPE_GMM_CFG[4] TBL | 0x- |
| Set the size of the gamma table. | IPIPE_GMM_CFG[6:5]SIZ | 0x- |
| (optional) Insert bypass bit for each color. | IPIPE_GMM_CFG[0] BYPR IPIPE_GMM_CFG[1] BYPG IPIPE_GMM_CFG[2] BYPB | 0x1 |

8.3.4.4.1.2.6 Subsequence – ISS ISP IPIPE 2nd RGB2RGB Conversion Matrix Initialization

Table 8-361. ISS ISP IPIPE 2nd RGB2RGB Conversion Matrix Initialization

| Step | Register/Bit Field/Programming Model | Value |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| Set the gain range. | IPIPE_RGB2_MUL_RR[10:0] VAL IPIPE_RGB2_MUL_GR[10:0] VAL IPIPE_RGB2_MUL_BR[10:0] VAL IPIPE_RGB2_MUL_RG[10:0] VAL IPIPE_RGB2_MUL_GG[10:0] VAL IPIPE_RGB2_MUL_BG[10:0] VAL IPIPE_RGB2_MUL_RB[10:0] VAL IPIPE_RGB2_MUL_GB[10:0] VAL IPIPE_RGB2_MUL_BB[10:0] VAL | 0x- |
| Set the offset. | IPIPE_RGB2_OFT_OR[10:0] VAL IPIPE_RGB2_OFT_OG[10:0] VAL IPIPE_RGB2_OFT_OB[10:0] VAL | 0x- |

| Enable IPIPE module. | IPIPE_SRC_EN[0] EN | 0x1 |

8.3.4.5 ISS ISP RSZ Programming Model

This section discusses programming configuration steps related to software control of the RSZ. It lists the registers that must be programmed in different modes, describes how to enable and disable the RSZ and how to check the status of the image resizing procedure, and discusses the different register access types and several programming constraints.

8.3.4.5.1 ISS ISP RSZ Hardware Setup/Initialization

This section discusses the configuration of the RSZ required before image processing can begin.

8.3.4.5.1.1 ISS ISP RSZ Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the RSZ module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration and environment of the RSZ. For more information, see [Section 8.3.3.5.4](#), *ISS ISP RSZ Integration..*

Table 8-371. ISS ISP RSZ Surrounding Modules Global Initialization

| Surrounding Modules | Comments |
|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PRCM | Module Interface and functional clocks must be enabled. RSZ is part of ISP, which is part of ISS. To enable the clocks for ISS, see Chapter 3 , <i>Power, Reset, and Clock Management</i> . Also see Section 8.3.2.1.1 , <i>ISS ISP Clocks</i> . |
| (optional) MPU INTC | The MPU INTC must be configured to enable interrupts from the RSZ. For information about how to configure the local ISS interrupt channels, see Section 8.3.2.2 , <i>ISS ISP Interrupt Tree</i> , and Section 8.1.2.1.1 , <i>ISS Interrupt Merger</i> . Then, to configure the outside ISS boundary channels, see Chapter 17 , <i>Interrupt Controllers</i> . |
| (optional) IPIPE | Configure the IPIPE module to process and pass data to the RSZ module. See Section 8.3.4.4 , <i>ISS ISP IPIPE Programming Model</i> . |
| (optional) IPIPEIF | Configure the IPIPEIF module to process and pass data to the RSZ module. See Section 8.3.4.3 , <i>ISS ISP IPIPEIF Programming Model</i> . |
| (optional) BL | Configure the BL for reading back data from memory. See Section 8.3.4.7 , <i>ISS ISP BL Programming Model</i> . |
| (optional) CSI2 | If the data comes from the sensor, configure the CSI2-A interface. See Section 8.2.5.4 , <i>ISS CSI2 Programming Model</i> . |
| (optional) CCP2 | If the data comes from the sensor, configure the CCP2 interface. See Section 8.2.4.4 , <i>ISS CCP2 Programming Model</i> . |

NOTE: The MPU INTC configurations are necessary if the interrupt-based communication modes are used. The IPIPE or IPIPEIF configuration is also necessary for putting data into the RSZ. Moreover, if data comes from memory, the BL must be configured. If data comes from the image sensor CSI2 or CCP2, the interface must be configured.

8.3.4.5.1.2 ISS ISP RSZ Initial Register Setup

Before enabling the RSZ, the hardware must be properly configured through register writes. [Table 8-372](#) identifies the sequence to be used before enabling the hardware.

Table 8-372. ISS ISP RSZ Initial Register Setup

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------|-------|
| Set the MMR clock to enable RSZ register read/write access. | RSZ_GCK_MMR [0] MMR | 0x1 |
| Determine whether or not a bypass mode will be used and set the RSZ core functional clock accordingly. | RSZ_GCK_SDR [0] CORE | 0x- |
| IF: Is the core clock enabled? | RSZ_GCK_SDR [0] CORE | = 0x1 |
| Enable RSZ engine clocks. | RSZ_SYSCONFIG [8] RSZA_CLK_EN RSZ_SYSCONFIG [9] RSZB_CLK_EN | 0x1 |
| ELSE: The input data buffer is not used? | RSZ_GCK_SDR [0] CORE | = 0x0 |
| Set the bypass mode accordingly. | RSZ_SRC_FMT0 [1] BYPASS | 0x- |
| ENDIF | | |
| Enable the RSZ core clock. | RSZ_GCK_SDR [0] CORE | 0x1 |
| Determine the upscale ratio and functional clock, and adjust the fractional clock divider as appropriate. | RSZ_FRACDIV [15:0] RSZ_FRACDIV | 0x- |
| Set the low threshold of the RSZ input data buffer as appropriate. | RSZ_IN_FIFO_CTRL [28:16] THRLD_LOW | 0x- |
| Set the high threshold of the RSZ input data buffer as appropriate. | RSZ_IN_FIFO_CTRL [12:0] THRLD_HIGH | 0x- |
| Determine whether IPIPE or IPEPIF will be the source of input and set this bit accordingly. | RSZ_SRC_FMT0 [0] SEL | 0x- |
| Determine whether the RSZ will be processing as long as data is present in the input buffer, or whether it will wait for a WEN signal from the input source (IPIPE or IPIPEIF) to process lines only arrived during WEN high state. | RSZ_SRC_MODE [1] WRT | 0x- |
| Select the processing mode (one shot or free running). This bit controls the RSZ module. There are also additional mode settings for the two RSZ engines within. After RSZ reset, the mode is automatically set to free running. | RSZ_SRC_MODE [0] OST | 0x- |
| Configure the number of interrupt intervals for writing lines into CBUFF for the two RSZ engines. | RSZ_IRQ_RZA [12:0] RZA RSZ_IRQ_RZB [12:0] RZB | 0x- |
| Enable the RSZ module. | RSZ_SRC_EN [0] EN | 0x1 |
| Enable the RSZ engine A. | RZA_EN [0] EN | 0x1 |
| Enable the RSZ engine B. | RZB_EN [0] EN | 0x1 |

NOTE: RSZ engine A or RSZ engine B must be enabled after setting all needed configuration parameters.

8.3.4.5.1.3 ISS ISP RSZ Reset Behavior

Because the RSZ module has no software reset, software can issue one at the ISP level. Moreover, upon hardware reset, all the registers in the RSZ are reset to their reset values. [Table 8-373](#) identifies the proper software sequence before and after RSZ reset issues at the ISP level.

Table 8-373. ISS ISP RSZ Reset Behavior

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------------------------------------|--------------------------------------------------------------------------------------------|-------|
| ELSE IF: Is FIFO overflow or blanking error present? | ISP5_IRQSTATUS_[18] RSZ_FIFO_IN_OVF or ISP5_IRQSTATUS_[19] RSZ_FIFO_IN_BLK_ERR | = 0x1 |
| Clear the FIFO blanking event. | ISP5_IRQENABLE_CLR_[19] RSZ_FIFO_IN_BLK_ERR | 0x1 |
| Clear the overflow event. | SP5_IRQENABLE_CLR_[18] RSZ_FIFO_IN_OVF | 0x1 |
| ELSE: No FIFO overflow or blanking error is present? | | |
| Wait until there is no DMA process and the module ready for reset. | ISP5_SYSCONFIG[1] SOFTRESET and ISP5_IRQSTATUS_[15] RSZ_INT_DMA | = 0x0 |
| ENDIF | | |
| Disable the source data. | RSZ_SRC_EN[0] EN | 0x0 |
| Reset the RSZ at the ISP level. | ISP5_SYSCONFIG[1] SOFTRESET | 0x1 |
| Check whether the RSZ has been reset properly. | ISP5_SYSCONFIG[1] SOFTRESET | 0x- |

8.3.4.5.2 ISS ISP RSZ Global Image Processing Settings

This section discusses the configuration of the RSZ global settings before/during image frame processing. [Table 8-374](#) identifies the global RSZ functional sequence, which includes global control, frame settings, bandwidth control and reversal output image frames.

Table 8-374. ISS ISP RSZ Global Image Processing Settings

| Step | Register/Bit Field/Programming Model | Value |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| Initialize the RSZ module. | See Section 8.3.4.5.1 . | |
| Determine input data type and configure the source parameters. | See Section 8.3.4.5.2.1 . | |
| Determine if vertical flip of the output image will be performed by the two RSZ engines and set accordingly. | RSZ_SEQ[1] VRVA RSZ_SEQ[3] VRVB | 0x- |
| Determine if horizontal flip of the output image will be performed by the two RSZ engines and set accordingly. | RSZ_SEQ[0] HRVA RSZ_SEQ[2] HRVB | 0x- |
| Set the baseline address of the RSZ output to CBUFF. Best performance can be achieved by assigning address on a 128-byte boundary. | RZA_SDR_Y_BAD_H[15:0] Y_BAD_H RZA_SDR_Y_BAD_L[15:0] Y_BAD_L RZB_SDR_Y_BAD_H[15:0] Y_BAD_H RZB_SDR_Y_BAD_L[15:0] Y_BAD_L RZA_SDR_C_BAD_H[15:0] C_BAD_H RZA_SDR_C_BAD_L[15:0] C_BAD_L RZB_SDR_C_BAD_H[15:0] C_BAD_H RZB_SDR_C_BAD_L[15:0] C_BAD_L | 0x- |
| Set the start address of the RSZ output to CBUFF. The first data output will be written to this address. If the first line of a frame is written at the beginning of the CBUFF memory, then SAD = BAD and PTR_S = 0. It is strongly advised to set up this address on a 128-byte boundary, which will lead to the best performance. | RZA_SDR_Y_SAD_H[15:0] Y_SAD_H RZA_SDR_Y_SAD_L[15:0] Y_SAD_L RZB_SDR_Y_SAD_H[15:0] Y_SAD_H RZB_SDR_Y_SAD_L[15:0] Y_SAD_L RZA_SDR_C_SAD_H[15:0] C_SAD_H RZA_SDR_C_SAD_L[15:0] C_SAD_L RZB_SDR_C_SAD_H[15:0] C_SAD_H RZB_SDR_C_SAD_L[15:0] C_SAD_L | 0x- |
| Set the start pointer of the CBUFF internal counter. It must be set up as PTR_S = (SAD – BAD) / OFT. PTR_S is expressed in number of lines. | RZA_SDR_Y_PTR_S[12:0] Y_PTR_S RZB_SDR_Y_PTR_S[12:0] Y_PTR_S RZA_SDR_C_PTR_S[12:0] C_PTR_S RZB_SDR_C_PTR_S[12:0] C_PTR_S | 0x- |

Table 8-374. ISS ISP RSZ Global Image Processing Settings (continued)

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------|-------|
| Set the end pointer of the CBUFF internal counter. PTR_E is expressed in number of lines. The CBUFF can contain up to PTR_E lines. | RZA_SDR_Y_PTR_E[12:0] Y_PTR_E RZB_SDR_Y_PTR_E[12:0] Y_PTR_E RZA_SDR_C_PTR_E[12:0] C_PTR_E RZB_SDR_C_PTR_E[12:0] C_PTR_E | 0x- |
| Set the line of offset expressed in bytes between two lines in the CBUFF (Line 0 = SAD, Line 1 = SAD + 1 x OFT, Line 2 = SAD + 2 x OFT). PTR_E is expressed in number of lines. The CBUFF can contain up to PTR_E lines. Note: OFT does not necessarily correspond to the size of a line in a frame; it can be much bigger. The line offset must be a multiple of 128 bytes. | RZA_SDR_Y_OFT[16:0] Y_OFT RZB_SDR_Y_OFT[16:0] Y_OFT RZA_SDR_C_OFT[16:0] C_OFT RZB_SDR_C_OFT[16:0] C_OFT | 0x- |
| Determine output data type, whether it will be flipped, and configure the output memory addresses. | See Section 8.3.4.5.2.2 . | |

NOTE: When data output is 4:2:2 or 4:2:0-Y-only, the following values are not needed:

- RZx_SDR_C_BAD_x
- RZx_SDR_C_SAD_x
- RZx_SDR_C_PTR_S
- RZx_SDR_C_PTR_E
- RZx_SDR_C_OFT

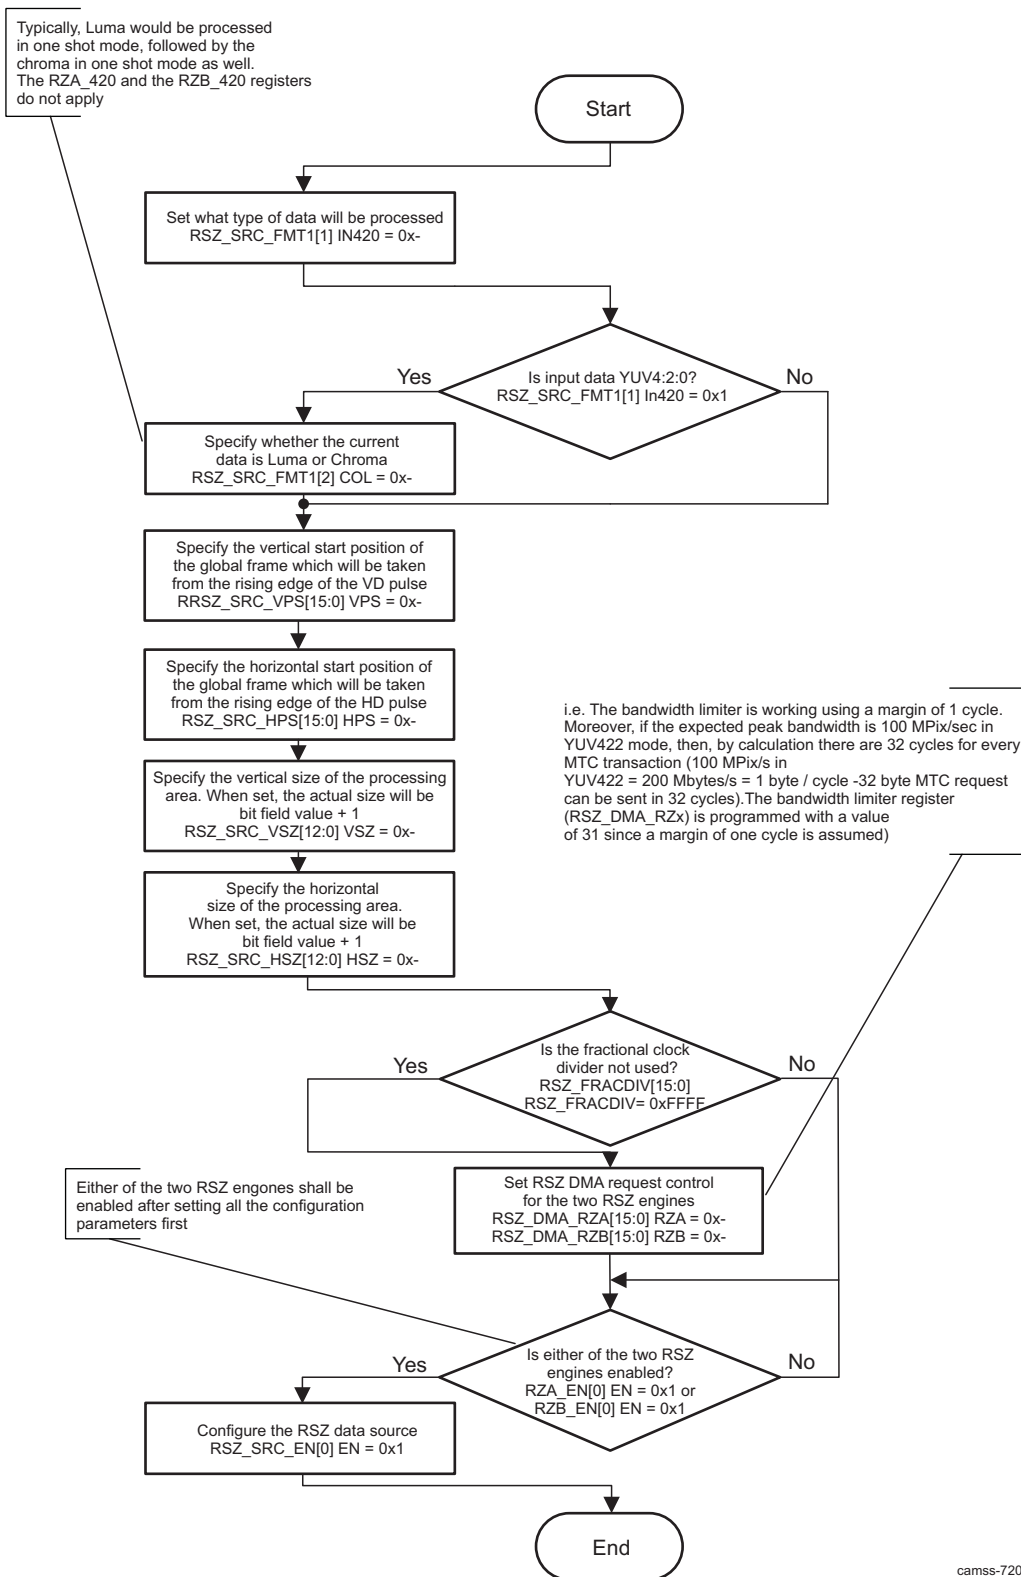

When output is 4:2:0-C-only, the following values are not needed:

- RZx_SDR_Y_BAD_x
- RZx_SDR_Y_SAD_x
- RZx_SDR_Y_PTR_S
- RZx_SDR_Y_PTR_E
- RZx_SDR_Y_OFT

8.3.4.5.2.1 ISS ISP RSZ Global Image Processing Settings – Subsequence 1

This procedure listed in [Figure 8-235](#) determines which of the RSZ engines are enabled and the type of input data, and configures the source data parameters

Figure 8-235. ISS ISP RSZ Global Image Processing Settings – Subsequence 1

camss-720

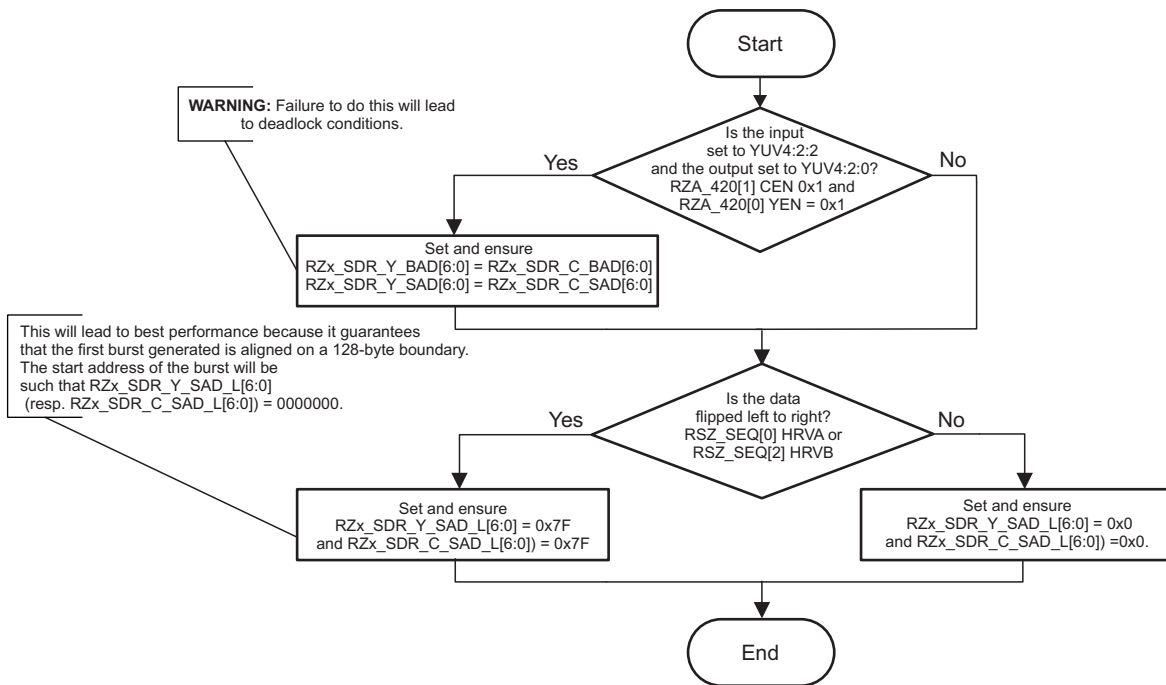

Table 8-375. Register Call Summary for ISS ISP RSZ Global Image Processing Settings – Subsequence 1

| Register Name | Register Name | Register Name |
|-----------------------|-----------------------|-------------------------------|
| RZA_420[1] CEN | RZA_420[0] YEN | RSZ_SRC_FMT1[1] IN420 |

8.3.4.5.3 ISS ISP RSZ Engines Interframe Image Processing Settings

This section discusses the configuration of the RSZ interframe image processing. Table 8-377 identifies the setup sequence for the two different engines within the RSZ module.

Table 8-377. ISS ISP RSZ Engines Interframe Image Processing Settings

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|-------|
| IF: Is the resizer module set to free-running mode? | RSZ_SRC_MODE[0] OST | = 0x0 |
| Set either of the engines to free-running mode to keep popping data out of the internal buffer. Otherwise, it will lead to an overflow event after the first frame. | RZA_MODE[0] MODE RZB_MODE[0] MODE | 0x0 |
| ELSE: Is the resizer module set to one-shot mode? | | |
| Set both RSZ engines to one-shot mode. | RZA_MODE[0] MODE RZB_MODE[0] MODE | 0x1 |
| ENDIF | | |
| Set the output format. See Table 8-322 . | RZA_420[0] YEN RZA_420[1] CEN RZB_420[0] YEN RZB_420[1] CEN | 0x- |
| On the side of the RSZ_SRC_VPS , RSZ_SRC_HPS , RSZ_SRC_VSZ , and RSZ_SRC_HSZ registers, set the engine complementary function to crop within the global frame and assign proper vertical start position of the input frame. ⁽¹⁾ | RZA_I_VPS[12:0] VPS RZB_I_VPS[12:0] VPS | 0x- |
| Assign proper horizontal start position of the input frame. | RZA_I_HPS[12:0] HPS RZB_I_HPS[12:0] HPS | 0x- |
| Assign proper vertical size of the output frame. | RZA_O_VSZ[12:0] VPS RZB_O_VSZ[12:0] VPS | 0x- |
| Assign proper horizontal size of the output frame. | RZA_O_HSZ[12:1] HPS RZB_O_HSZ[12:1] HPS | 0x- |
| Set the phase position for the Chroma and Luma element and configure the averager. | See Section 8.3.4.5.3.1 | |
| Set the vertical resize value for the two engines. (vertical resize ration = 256 / RZx_V_DIF). | RZA_V_DIF[13:0] V RZB_V_DIF[13:0] V | 0x- |
| Set the horizontal resize value for the two engines. (horizontal resize ration = 256 / RZx_H_DIF). | RZA_H_DIF[13:0] H RZB_H_DIF[13:0] H | 0x- |
| Select vertical method of resizing filtering (linear or cubic interpolation) for the Luma and Chroma elements. | RZA_V_TYP[0] Y RZB_V_TYP[0] Y RZA_V_TYP[1] C RZB_V_TYP[1] C | 0x- |
| Select horizontal method of resizing filtering (linear or cubic interpolation) for the Luma and Chroma elements. | RZA_H_TYP[0] Y RZB_H_TYP[0] Y RZA_H_TYP[1] C RZB_H_TYP[1] C | 0x- |
| IF: Is the interpolation method linear? | RZx_V_TYP[0] Y AND RZx_V_TYP[1] C RZx_H_TYP[0] Y AND RZx_H_TYP[1] C | = 0x1 |
| Set the needed vertical LPF intensity for the Luma and Chroma elements. | RZA_V_LPF[5:0] Y RZA_V_LPF[11:6] C RZB_V_LPF[5:0] Y RZB_V_LPF[11:6] C | 0x- |
| Set the needed horizontal LPF intensity for the Luma and Chroma elements. | RZA_H_LPF[5:0] Y RZA_H_LPF[11:6] C RZB_H_LPF[5:0] Y RZB_H_LPF[11:6] C | 0x- |
| ENDIF | | |
| Set the Chroma saturation MAX and MIN values. | RSZ_YUV_C_MAX[7:0] MAX RSZ_YUV_C_MIN[7:0] MIN | 0x- |
| Set the Luma saturation MAX and MIN values. | RSZ_YUV_Y_MAX[7:0] MAX RSZ_YUV_Y_MIN[7:0] MIN | 0x- |

⁽¹⁾ The size of the frame (height of the image) after the cropping must be two lines or larger.

Table 8-377. ISS ISP RSZ Engines Interframe Image Processing Settings (continued)

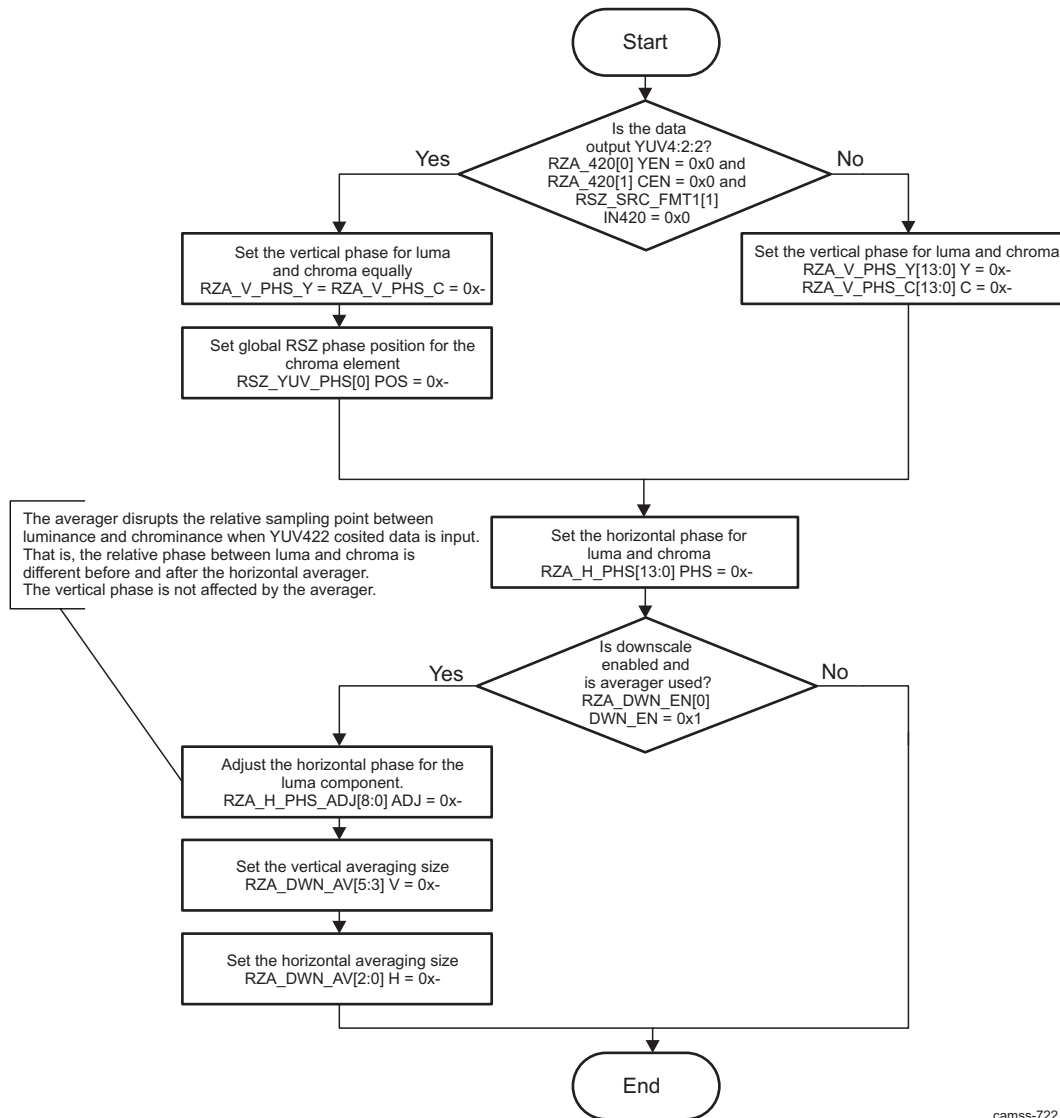

| Step | Register/Bit Field/Programming Model | Value |
|--------------------------------------------------------------------------------------------------------|-------------------------------------------|-------|
| (optional) Set the mode to RGB conversion, configure the alpha value and set additional pixel masking. | See Section 8.3.4.5.3.2 . | |

8.3.4.5.3.1 ISS ISP RSZ Engines Interframe Image Processing Settings – Subsequence 1

The procedure shown in [Figure 8-237](#) sets the phase position for the Chroma and Luma elements and configures the averager.

NOTE: This procedure configures RSZ engine A. The procedure for RSZ engine B is identical.

Figure 8-237. ISS ISP RSZ Engines Interframe Image Processing Settings – Subsequence 1

NOTE: When masking is used, boundaries affect the leftmost/rightmost 2 pixels in up-conversion.

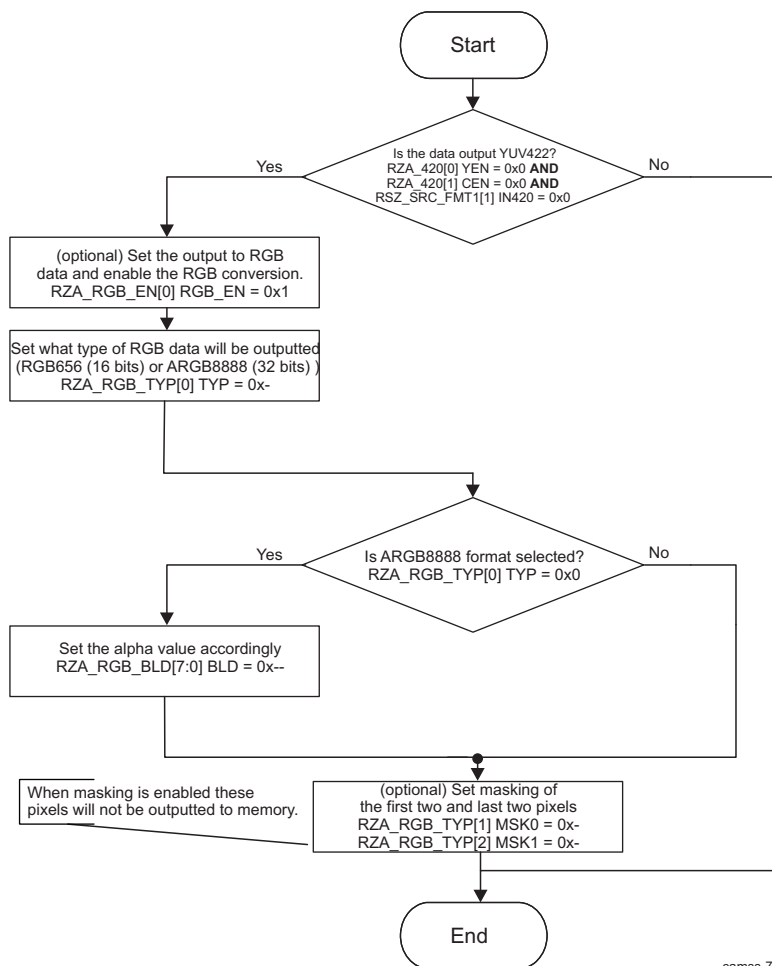

Table 8-378. Register Call Summary for ISS ISP RSZ Engines Interframe Image Processing Settings – Subsequence 1

| Register Name | Register Name | Register Name |

8.3.4.5.4 ISS ISP RSZ Programming Constraints

The RSZ module contains shadowed and nonshadowed registers. Shadowed registers can be updated at anytime during the resizing operation, but the new setting does not take effect until the next `rsz_int_reg` event. Shadowed registers can be updated for the next frame after the `rsz_int_reg` event triggers.

Nonshadowed registers must be programmed before enabling the RSZ module or between frames (that is, after the `rsz_int_dma` has come [and the entire frame has come on the VPORT IF] and before the VD of the next frame.) [Table 8-380](#) list the nonshadowed registers.

Table 8-380. ISS ISP RSZ Nonshadowed Registers

| Nonshadowed Registers |
|----------------------------------|
| RSZ_SYSCONFIG |
| RSZ_IN_FIFO_CTRL |
| RSZ_GCK_MMR |
| RSZ_GCK_SDR |
| RSZ_SRC_MODE |

| RSZ_SRC_EN |

8.3.4.6 ISS ISP H3A Programming Model

This section discusses issues related to the software control of the H3A module. It lists which registers are required to be programmed in different modes, how to enable and disable the H3A, how to check the status of the H3A, discusses the different register access types, and enumerates several programming constraints.

8.3.4.6.1 ISS ISP H3A Hardware Setup/Initialization

This section discusses the configuration of the H3A required before image processing can begin.

8.3.4.6.1.1 ISS ISP H3A Reset Behavior

Upon hardware reset of the ISP, all of the registers in the H3A are reset to their reset values.

8.3.4.6.1.2 ISS ISP H3A Register Setup

For register configuration purposes, the AF engine and the AEW engine of the H3A can be configured independently. Because there are separate enable bits for each engine, this section is divided into the AF engine and the AEW engine.

8.3.4.6.1.2.1 ISS ISP H3A AF Engine

Before enabling the AF engine, the hardware must be properly configured through register writes. [Table 8-381](#) lists the register parameters that must be programmed before enabling the AF engine of the H3A.

Table 8-381. ISS ISP H3A AF Engine Required Configuration Parameters

| Step | Configuration Required | Value |
|-------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|
| AF optional preprocessing settings | | |
| Note: A suggestion is to use the averaging filter in the IPIPEIF to reduce noise before generating AF statistics. | | |
| Enable or disable the median filter. | H3A_PCR[2] AF_MED_EN | |
| Set the median filter threshold, if the filter is enabled. | H3A_PCR[10:3] MED_TH | |
| Enable or disable A-Law compression. | H3A_PCR[1] AF_ALAW_EN | |
| Set AF general settings. | | |
| Set the focus value accumulation mode. | H3A_PCR[14] FVMODE | |
| Set the input start information. | H3A_LINE_START[31:16] SLV H3A_LINE_START[15:0] LINE_START | |
| Set the output SDRAM destination start address. | H3A_AFBUFST[31:5] AFBUFST | |
| RGB pixel extraction and paxel settings | | |
| Set the RGB positions in the pixel. | H3A_PCR[13:11] RGBPOS | |
| Set the paxel width. | H3A_AFPAX1[23:16] PAXW | |
| Set the paxel height. | H3A_AFPAX1[7:0] PAXH | |
| Set the paxel horizontal start position. | H3A_AFPAXSTART[27:16] PAXSH | |
| Set the paxel vertical start position. | H3A_AFPAXSTART[11:0] PAXSV | |
| Set the column increment. | H3A_AFPAX2[20:17] AFINCH | |
| Set the line increment. | H3A_AFPAX2[16:13] AFINCV | |
| Set the vertical paxel count. | H3A_AFPAX2[12:6] PAXVC | |
| Set the horizontal paxel count. | H3A_AFPAX2[5:0] PAXHC | |
| Horizontal focus value calculator settings | | |
| Set the horizontal threshold for the two IIR. | H3A_HVF_THR[31:16] HTHR2 H3A_HVF_THR[15:0] HTHR1 | |
| Set the IIR horizontal start position. | H3A_AFIIRSH[11:0] IIRSH | |
| Set the coefficients for the SET 0 IIR. | H3A_AFcoef010 H3A_AFcoef032 H3A_AFcoef054 H3A_AFcoef076 H3A_AFcoef098 H3A_AFcoef0010 | |
| Set the coefficients for the SET 1 IIR. | H3A_AFcoef110 H3A_AFcoef132 H3A_AFcoef154 H3A_AFcoef176 H3A_AFcoef198 H3A_AFcoef1010 | |
| Vertical focus value calculator settings | | |
| Enable or disable vertical AF focus value calculation. | H3A_PCR[20] AF_VF_EN | |
| Set the vertical FIR 1 coefficients and threshold. | H3A_VFV_CFG1 H3A_VFV_CFG2 | |
| Set the vertical FIR 2 coefficients and threshold. | H3A_VFV_CFG3 H3A_VFV_CFG4 | |

The following references offer guidelines on how to program the filter coefficients and make use of the H3A output.

8.3.4.6.1.2.2 ISS ISP H3A AEW Engine

Before enabling the AEW engine, the hardware must be properly configured through register writes. [Table 8-382](#) lists the register parameters that must be programmed before enabling the AEW engine of the H3A.

Table 8-382. ISS ISP H3A AEW Engine Required Configuration Parameters

| Step | Configuration Required | Value |
|-------------------------------------------------------------------|----------------------------------------------------------------------------------------------|-------|
| AEW optional preprocessing settings | | |
| Enable or disable median filter. | H3A_PCR[19] AEW_MED_EN | |
| Set the median filter threshold. | H3A_PCR[10:3] MED_TH | |

8.3.4.6.2 ISS ISP H3A Enable/Disable Hardware

Setting the [H3A_PCR\[0\] AF_EN](#) bit enables the AF engine, and the [H3A_PCR\[16\] AEW_EN](#) bit enables the AEW engine. This must be done after all of the required registers discussed in the previous section are programmed.

The H3A operates in continuous mode. Processing of the frame is dependent upon the timing of the IPIPEIF. To ensure that data from the IPIPEIF is not missed, the H3A must be enabled before the IPIPEIF. In this way, the H3A waits for data from the IPIPEIF. The AF engine or the AEW engine can be disabled by clearing the [H3A_PCR\[0\] AF_EN](#) or [H3A_PCR\[16\] AEW_EN](#) bit, respectively, during the processing of the last frame. The disable is latched in at the end of the frame in which it was written.

8.3.4.6.3 ISS ISP H3A Register Accessibility During Frame Processing

There are two types of register access in the H3A module:

- Shadow registers

These registers/fields can be read and written (if the field is writable) at any time. However, the written values take effect only at the start of a frame. Reads still return the most recent write even though the settings are not used until the next start of frame.

The only shadowed registers in the H3A module are:

- [H3A_AFPAX1](#)
- [H3A_AFPAX2](#)
- [H3A_AFPAXSTART](#)
- [H3A_AFIIRSH](#)
- [H3A_AEWWIN1](#)
- [H3A_AEWINSTART](#)
- [H3A_AEWINBLK](#)
- [H3A_AEWSUBWIN](#)
- [H3A_AEWCFG](#)
- [H3A_AEWBUFST](#)

- Busy-lock registers

All other registers, except those described previously, belong to this category.

Busy-lock registers cannot be written when the module is busy ([H3A_PCR\[15\] BUSYAF == 1](#) OR [H3A_PCR\[18\] BUSYAEAWB == 1](#)). Writes are allowed to occur, but no change occurs in the registers (blocked writes from the hardware perspective, but allowed write from the software perspective). Once the busy bit in the [H3A_PCR](#) register ([H3A_PCR\[15\] BUSYAF](#) or [H3A_PCR\[18\] BUSYAEAWB](#) bit) is reset to 0, the busy-lock registers can be written.

The ideal procedure for changing the H3A registers if ([H3A_PCR\[15\] BUSYAF == 0](#) or [H3A_PCR\[18\] BUSYAEAWB == 0](#)) or if (EOF interrupt occurs) is:

1. Disable AF or AE/AWB.
2. Change registers.
3. Enable AF or AE/AWB.

8.3.4.6.4 ISS ISP H3A Interframe Operations

Between frames, it may be necessary to modify the memory pointers before processing the next frame. Because the [H3A_PCR](#) register and memory pointer registers are shadowed, these modifications can take place any time before the end of the frame, and the data will be latched in for the next frame. The host controller can perform these changes upon receiving an interrupt.

8.3.4.6.5 ISS ISP H3A Summary of Constraints

The following is a list of register configuration constraints to adhere to when programming the H3A. It can be used as a quick checklist. More detailed register setting constraints can be found in the individual register descriptions.

- The output addresses ([H3A_AFBUFST](#)[31:5] AFBUFST and) must be on 64-byte boundaries
- Each horizontal row of paxels () or windows () starts on a 32-byte boundary.
- If the pixel clock frequency < ISP_FCLK/2 and vertical focus is enabled, the constraints listed in [Table 8-383](#) apply.

Table 8-383. ISS ISP H3A Constraints When PCLK < ISP_FCLK/2 and Vertical Focus Enabled

| Field | Constraint |
|----------------------------------------------|-----------------------------------------------------|
| H3A_AEWWIN1 [20:13] WINW | > 7 |
| H3A_AFPAX1 [23:16] PAXW | > 7 |
| H3A_AFIIRSH [11:0] IIRSH | None |
| H3A_AFPAXSTART [27:16] PAXSH | \geq H3A_AFIIRSH [11:0] IIRSH + 2 |
| H3A_AFPAX2 [20:17] AFINCH | None |
| H3A_AFPAX2 [5:0] PAXHC | \leq 11 |

- the If pixel clock frequency < ISP_FCLK/2 and vertical focus is disabled, the constraints listed in [Table 8-384](#) apply.

Table 8-384. ISS ISP H3A Constraints When PCLK < ISP_FCLK/2 and Vertical Focus Disabled

| Field | Constraint |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| H3A_AEWWIN1 [20:13] WINW | > 7 |
| H3A_AFPAX1 [23:16] PAXW | > 7 |
| H3A_AFIIRSH [11:0] IIRSH | Must be even |
| H3A_AFPAXSTART [27:16] PAXSH | \geq H3A_AFIIRSH [11:0] IIRSH + 2 and must be even |
| H3A_AFPAX2 [20:17] AFINCH | $(1 + \text{H3A_AFPAX1}[23:16] \text{ PAXW} / \text{H3A_AFPAX2}[20:17] \text{ AFINCH}) * \text{H3A_AFPAX2}[5:0] \text{ PAXHC}$ must be between 4 and 384 |
| H3A_AFPAX2 [5:0] PAXHC | \leq 35 |

- If the pixel clock frequency \geq ISP_FCLK/2 and vertical focus is enabled, the constraints listed in [Table 8-385](#) apply.

Table 8-385. ISS ISP H3A Constraints When PCLK \geq ISP_FCLK/2 and Vertical Focus Enabled

| Field | Constraint |
|----------------------------------------------|-----------------------------------------------------|
| H3A_AEWWIN1 [20:13] WINW | > 15 |
| H3A_AFPAX1 [23:16] PAXW | > 15 |
| H3A_AFIIRSH [11:0] IIRSH | None |
| H3A_AFPAXSTART [27:16] PAXSH | \geq H3A_AFIIRSH [11:0] IIRSH + 2 |
| H3A_AFPAX2 [20:17] AFINCH | None |
| H3A_AFPAX2 [5:0] PAXHC | \leq 11 |

- If the pixel clock frequency \geq ISP_FCLK/2 and vertical focus is disabled, the constraints in [Table 8-386](#) apply.

Table 8-386. ISS ISP H3A Constraints When PCLK \geq ISP_FCLK/2 and Vertical Focus Disabled

| Field | Constraint |
|----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| H3A_AEWWIN1 [20:13] WINW | > 15 |
| H3A_AFPAX1 [23:16] PAXW | > 15 |
| H3A_AFIIRSH [11:0] IIRSH | Must be even |
| H3A_AFPAXSTART [27:16] PAXSH | \geq H3A_AFIIRSH [11:0] IIRSH + 2 and must be even |
| H3A_AFPAX2 [20:17] AFINCH | $(1 + \text{H3A_AFPAX1}[23:16] \text{ PAXW} / \text{H3A_AFPAX2}[20:17] \text{ AFINCH}) * \text{H3A_AFPAX2}[5:0] \text{ PAXHC}$ must be between 4 and 384 and $\text{H3A_AFPAX2}[20:17] \text{ AFINCH} \text{ modulo } \text{H3A_AFPAX1}[23:16] \text{ PAXW} \neq 1$ |

Table 8-386. ISS ISP H3A Constraints When PCLK \geq ISP_FCLK/2 and Vertical Focus Disabled (continued)

| Field | Constraint |
|-----------------------|------------|
| H3A_AFPAX2[5:0] PAXHC | ≤ 35 |

AF engine

- The paxel horizontal start value must be greater than or equal to the IIR horizontal start position.
- The paxel start/end and IIR filter start positions must not be set within the first 2 and the last 2 pixels (to check).
- The width (H3A_AFPAX1[23:16] PAXW) and height (H3A_AFPAX1[7:0] PAXH) of the paxels must be an even number.
- The minimum width of the paxel (H3A_AFPAX1[23:16] PAXW) must be 16 pixels, if the pixel clock is half or less of the ISP_FCLK clock. If the pixel clock is equal to ISP_FCLK, then the minimum width is 32 pixels.
- The number of columns to increment in a paxel (H3A_AFPAX2[20:17] AFINCH) must be even and is restricted to 2 to 32.
- The number of lines to increment in a paxel (H3A_AFPAX2[16:13] AFINCV) must be even and is restricted to 0 to 30.
- The maximum number of vertical paxels in a frame (H3A_AFPAX2[12:6] PAXVC) must not exceed 128.
- The number of paxels in the horizontal direction (H3A_AFPAX2[5:0] PAXHC) has a valid range from 1 to 35.
- If vertical mode is enabled:
 - Paxel horizontal start position (H3A_AFPAXSTART[27:16] PAXSH) must be even.
 - The lower bit of the H3A_AFPAXSTART[27:16] PAXSH bit field and the lower bit of the H3A_AFIIRSH[11:0] IIRSH bit field must be equal.
 - The H3A_AFPAXSTART[11:0] PAXSV bit field must be ≥ 8 .
- If vertical mode is not enabled, the H3A_AFIIRSH[11:0] IIRSH bit field must be even.
- Paxels cannot overlap the last pixel in a line.
- Paxels must be adjacent to one another.

AEW engine

- The width (H3A_AEWWIN1[20:13] WINW) and height (H3A_AEWWIN1[31:24] WINH) of the windows must be an even number.
- The minimum width of the window (H3A_AEWWIN1[20:13] WINW) must be 16 pixels, if the pixel clock is half or less of the ISP_FCLK clock. If the pixel clock is equal to ISP_FCLK, then the minimum width is 32 pixels.
- The window height (H3A_AEWWIN1[31:24] WINH) has a valid range from 2 to 512.
- The maximum number of vertical windows in a frame (H3A_AEWWIN1[12:6] WINVC) must not exceed 128.
- The number of horizontal windows (H3A_AEWWIN1[5:0] WINHC) has a valid range from 1 to 35.
- Vertical and horizontal window start position (H3A_AEWWINSTART) has a valid range from 0 to 4095.
- Vertical window start position for single black lines (H3A_AEWINBLK[27:16] WINSV) has a valid range from 0 to 4095.
- Horizontal window start position for single black lines (H3A_AEWINBLK[6:0] WINH) must be even and has a valid range from 2 to 256.
- Subsampling windows can start only on even numbers.
- Vertical and horizontal sampling point increment (H3A_AEWSUBWIN) has a valid range from 2 to 32.

8.3.4.7 ISS ISP BL Programming Model

The procedure listed in [Table 8-387](#) initializes the buffer logic.

Table 8-387. ISS ISP BL Settings

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------------------------------------------------------|-------------------------------------------------|-------|
| Sets the memory access priority registers | ISP5_MPSR | |
| Sets the minimum interval between two memory requests for ISIF read port | ISP5_BL_MTC_1 [31:16] ISIF_R | |
| Sets the minimum interval between two memory requests for IPIPEIF read port | ISP5_BL_MTC_1 [15:0] IPIPEIF_R | |
| Sets the minimum interval between two memory requests for H3A write port | ISP5_BL_MTC_1 [31:16] H3A_W | |
| Set the maximum number of CIDs/tags that the BL can use. | ISP5_CTRL [7:4] VBUSM_CIDS | |
| Set the BL VBUSM priority setting. | ISP5_CTRL [3:1] VBUSM_CPRIORITY | |
| Set write posted/nonposted. | ISP5_CTRL [0] OCP_WRNP | |
| Enable the BL clock. | ISP5_CTRL [15] BL_CLK_ENABLE | 0x1 |

Backup mode, for debug only.</p> <p>0x3: Reserved</p> <p>0x2: Smart-standby mode: local initiator standby status depends on local conditions, that is, the module's functional requirement from the initiator. IP module must not generate (initiator-related) wake-up events. Generation of the MStandby signal must be initiated by the firmware by writing <code>ISP5_CTRL.MSTANDBY = 1</code>.</p> | RW | 0x2 |
| 3:2 | RESERVED | | R | 0x0 |
| 1 | SOFTRESET | <p>Software reset.</p> <p>The soft reset will cause the MStandby to be asserted as the reset value of the <code>ISP5_CTRL.MSTANDBY</code> bit is 1. After a soft reset, the software must ensure not to perform any access for 16 clock cycles (OCP-slave port frequency) after writing this bit. The OCP slave port is running at half the frequency of the functional clock. Before issuing a soft reset, the software must ensure that no more traffic is being generated by the ISP. Basically, it means that the camera module must be stopped from sending data and/or that the ISP modules are disabled. The last interrupt triggered by the ISP design upon completion of the frame processing is <code>rsz_int_dma</code>. This <code>rsz_int_dma</code> event must be used to enable clean termination of the processing. The software must wait a few hundred cycles to trigger the soft reset after upon assertion of the <code>rsz_int_dma</code>, this is to ensure that the BL is completely drained.</p> <p>Software must set the ISP in standby mode before issuing the soft reset: Set <code>ISP5_SYSCONFIG.STANDBYMODE = 2</code> (smart standby). Set <code>ISP5_CTRL.MSTANDBY</code> to 1. Poll for <code>ISP5_CTRL.MSTANDBY_WAIT = 1</code>. Then, the soft reset can be applied (<code>ISP5_SYSCONFIG.SOFTRESET = 1</code>).</p> <p>Write 0x0: No action Write 0x1: Initiate software reset Read 0x1: Reset (software or other) ongoing Read 0x0: Reset done, no pending action</p> | RW | 0 |
| 0 | AUTO_IDLE | Auto clock gating. Always enabled. | R | 1 |

Table 8-398. ISP5_IRQSTATUS_RAW_i

| | | | |
|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|---------------|
| Address Offset | 0x0000 0024 + (0x10 * i) | Index | i = 0 to 3 |
| Physical Address | 0x5201 0024 + (0x10 * i) | Instance | ISS_ISP5_SYS1 |
| Description | Per-event raw interrupt status vector. Raw status is set even if event is not enabled. Write 1 to set the (raw) status, mostly for debug. The ISP outputs four interrupt lines, ISP_IRQ0 to ISP_IRQ3. Any internal ISP event can be merged on the four lines. A same event must be enabled on only one interrupt line. | | |

|-------|---------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-------|
| 23 | RSZ_INT_EOF1 | <p>RESIZER module event: This event signals that the BL has received the EOF signal from the resizer B engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory.</p> <p>Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending</p> | RW W1toSet | 0 |
| 22 | RSZ_INT_EOF0 | <p>RESIZER module event: This event signals that the BL has received the EOF signal from the resizer A engine which happens one the last transfer in the frame has happened. Note that because the BL has FIFOs it may take some additional time before true data transfer completion to memory.</p> <p>Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending</p> | RW W1toSet | 0 |
| 21:20 | RESERVED | | R | 0x0 |
| 19 | RSZ_FIFO_IN_BLK_ERR | <p>This event signals that the minimum vertical blanking period has not been respected causing errors in the input data buffering submodule. This event will be triggered when the rsz_int_reg event of frame N is triggered before the rsz_int_dma of frame N + 1. This event would typically happen at the transition between two frames because there is not enough vertical blanking between frames: the firmware must take care to ensure enough vertical blanking. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending</p> | RW W1toSet | 0 |
| 18 | RSZ_FIFO_OVF | <p>This event signals that overflow happened in the input data buffering submodule. This event would typically happen while processing a frame because the video port pixel clock is too high: the firmware must take care to use a lower pixel clock at the input of the resizer module. Depending on the mode being used, the overflow can happen at different places: 1. Bypass mode: overflow happened in the input circular buffer. 2. Pass through mode: overflow happened on the module output interface (MTC) 3. Normal resize mode: overflow happened in the input circular buffer. The hardware cannot recover from this error. It will be required to perform a reset of the IP.</p> <p>Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending</p> | RW W1toSet | 0 |

|------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-------|
| 17 | RSZ_INT_CYC_RZB | <p>RESIZER module event: This event is the circular interrupt for RESIZER #B. An event can be triggered every time that RSZ_IRQ_RZB output lines have been written out to the RZB_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, this value should be such that the circular buffer vertical size (set by the RZB_SDR_Y_PTR_E register) is a multiple of RSZ_IRQ_RZB.</p> <p>Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. This is not an issue since the start of the buffer is read first.</p> <p>Write 0x0: No action Write 0x1: Set event (debug) Read 0x1: Event pending Read 0x0: No event pending</p> | RW W1toSet | 0 |
| 16 | RSZ_INT_CYC_RZA | <p>RESIZER module event: This event is the circular interrupt for RESIZER #A. An event can be triggered every time that RSZ_IRQ_RZA output lines have been written out to the RZA_SDR_Y buffer. The range can go from 1 to 8192 lines. Usually, the circular buffer vertical size (set by the RZA_SDR_Y_PTR_E register) should be a multiple of RSZ_IRQ_RZA.</p> <p>Note that at the time the interrupt is triggered, the actual data write has not taken place. It may take a few hundred of cycles to complete the data write into system memory. | 3 | ISIF_INT_3 | LSC interrupt issued by 2D-LSC block. Four types of 2D-LSC can be generated and mapped to the INT_3 line. For more information, see Section 8.3.3.7.10.1.5, ISS ISP ISIF 2D-LSC Events and Status Checking . Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending | RW W1toClr | 0 |
| 2 | ISIF_INT_2 | VD interrupt 2 event. Read this bit to check the interrupt mapped to the INT_2 line. This interrupt is also set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.7.19.1, ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts . Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending | RW W1toClr | 0 |
| 1 | ISIF_INT_1 | VD interrupt 1 event. Read this bit to check the interrupt mapped to the INT_1 line. This interrupt is also set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.7.19.1, ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts . Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending | RW W1toClr | 0 |
| 0 | ISIF_INT_0 | VD interrupt 0 event. Read this bit to check the interrupt mapped to the INT_0 line. This interrupt is also set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.7.19.1, ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts . Write 0x0: No action Write 0x1: Clear (raw) event Read 0x1: Event pending Read 0x0: No (enabled) event pending | RW W1toClr | 0 |

NOTE: Setting the ISP submodule interrupts and mapping them to the ISP lines requires a configuration to receive the IRQ events at a higher ISS interrupt merger level. For information about how IRQ lines are handled at the ISP level, see [Table 8-307](#). For information about how IRQs are handled at the ISS top-level before the signals leave ISS boundaries, see [Section 8.1.2.1.1, ISS Interrupt Merger](#).

| 0 | ISIF_INT_0 | <p>VD interrupt 0 event. Set this bit to disable the interrupt mapped to the INT_0 line. This interrupt is set based on the VD pulse position after receiving a configured number of horizontal pulse signals. For more information, see Section 8.3.3.7.19.1, ISS ISP ISIF VDINT0, VDINT1 and VDINT2 Interrupts.</p> <p>Write 0x0: No action</p> <p>Write 0x1: Disable interrupt</p> <p>Read 0x1: Interrupt enabled</p> <p>Read 0x0: Interrupt disabled (masked)</p> | RW W1toClr | 0 |

Table 8-405. Register Call Summary for Register ISP5_IRQENABLE_CLR_i

ISS ISP

- [ISS ISP RSZ Reset Behavior: \[0\]](#)
- [ISS ISP5 SYS1 Register Summary: \[1\]](#)

NOTE: Setting or disabling the ISP submodule interrupts mapped to the ISP lines requires a configuration to receive or disable the IRQ events at a higher ISS interrupt merger level. For information about how IRQ lines are handled at the ISP level, see [Table 8-307](#). For information about how IRQs are handled at the ISS top-level before the signals leave ISS boundaries, see [Section 8.1.2.1.1, ISS Interrupt Merger](#).

| 1 | IPIPE_INT_HST | Clear for ISP DMA request generation on ISS_DMA1. This DMA request must be set to transfer the HIST data from the IPIPE internal RAM to memory. Write 0x0: No action Write 0x1: Disable DMA Read 0x1: DMA enabled Read 0x0: DMA disabled | RW W1toClr | 0 |

| Bits | Field Name | Description | Type | Reset |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 26 | HST_RD_CHK | <p>When the HISTOGRAM computation is enabled and the HST DMA request is not used to read out the data, this register ensures that the data is read fast enough, else an interrupt ISP5_IRQSTATUS2_i[5] IPIPE_HST_ERR is triggered.</p> <p>The hardware sets automatically this bit to 1 when software can start reading the memory.</p> | RW | 0 |
| <div style="border: 1px solid black; padding: 10px; background-color: #f0f0f0;"> <p>CAUTION</p> <p>It is the software responsibility to set this bit to 0 after reading the data. Once the MPU has read the histogram data, it must clear this register, else the ISP5_IRQSTATUS2_i[5] IPIPE_HST_ERR will occur.</p> </div> | | | | |
| | | <p>Write 0x0: Clears the signal to avoid error generation. The software must write this bit to 0 after the last data read.</p> <p>Write 0x1: Reserved</p> <p>Read 0x1: The MPU can read the data from the memory. Needs to complete fast enough to avoid the interrupt generation.</p> <p>Read 0x0: No interrupt generation can happen</p> | | |
| 25 | DPC_EVT_INI | <p>Select the IPIPE module event to be used to generate the DMA requests for the DPC submodule.</p> <p>0x0: IPIPE_INT_LAST_PIX event is selected.</p> <p>0x1: IPIPE_INT_DPC_INI event is selected.</p> | RW | 0 |
| 24 | MSTANDBY | <p>MStandby signal assertion and de-assertion control for power management transitions.</p> <p>After software reset, this bit is asserted.</p> <p>Write "1" to transition from normal mode to idle mode. The firmware needs to ensure that no more ISP processing is ongoing before setting up this bit.</p> <p>Write "0" to transition from idle mode to normal mode. The software should poll ISP5_CTRL.MSTANDBY_WAIT = 0 after writing ISP5_CTRL.MSTANDBY = 0 in a transition from idle to normal mode.</p> <p>0x0: De-assert MStandby signal. May not be immediate due to power management handshaking btw the MStandby and Wait signals.</p> <p>0x1: Assert MStandby signal</p> | RW | 1 |
| 23 | VD_PULSE_EXT | <p>VD pulse extension enable</p> <p>This bit enables or disables the VD extension bridge. By default, the bridge is enabled. At ISS level, it is expected that ISP5_CTRL.VD_PULSE_EXT = 1 when the VPORT gets data from the CSI2 RX module and ISP5_CTRL.VD_PULSE_EXT = 0 when the VPORT gets data from the parallel interface or the CCP2 RX module. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for start of frame comes.</p> <p>0x0: Disabled</p> <p>0x1: Enabled</p> | RW | 1 |
| 22 | PCLK_INV | <p>Pixel clock inversion</p> <p>This bit enables or disables pixel clock inversion. The ISP always samples the data on the rising edge of the pixel clock. Enabling the inversion shifts the resampling period by 1/2 a pixel clock period.</p> <p>0x0: Normal</p> <p>0x1: Inversed</p> | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 21 | MFLAG | MFlag signal generation control This bit controls how the OCP MFlag signal is generated on the ISS NOC. 0x0: The MFlag value is dynamic. 0x1: The MFlag value is static. The value is set with the ISP5_CTRL[3:1] VBUSM_CPRIORITY . | RW | 0 |
| 20 | MSTANDDBY_WAIT | MStandby / Wait power management status bit. The power management framework of the ISP is based on the handshaking of the MStandby and Wait signals. The software is not supposed to write inside the ISP slave port and initiate traffic when ISP5_CTRL.MSTANDBY bit is written. The software can poll this bit to know when Wait signal is deasserted. Read 0x1: MStandby signal is asserted. Read 0x0: MStandby signal is deasserted. | R | - |
| 19:16 | RESERVED | | R | 0x0 |
| 15 | BL_CLK_ENABLE | BL clock enable 0x0: Disable 0x1: Enable | RW | 0 |
| 14 | ISIF_CLK_ENABLE | ISIF clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for start of frame comes. 0x0: Disable 0x1: Enable | RW | 0 |
| 13 | H3A_CLK_ENABLE | H3A clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable | RW | 0 |
| 12 | RSZ_CLK_ENABLE | RESIZER clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable | RW | 0 |
| 11 | IPIPE_CLK_ENABLE | IPIPE clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable | RW | 0 |
| 10 | IPIPEIF_CLK_ENABLE | IPIPEIF clock enable The ISP will return OCP_ERROR if one tries to program the module MMR or memory when the clock is disabled. 0x0: Disable 0x1: Enable | RW | 0 |
| 9 | SYNC_ENABLE | PCLK Sync module enable. This bit may only be modified when the video port is not receiving data such as when data is read from the IPIPEIF module memory read port. 0x0: Disable 0x1: Enable | RW | 0 |
| 8 | PSYNC_CLK_SEL | PCLK Sync clock select. This bit selects the clock which is used to resynchronize the input pixel clock. 0x0: GCK_MMR. Can be used if the input pixel clock is always lower than 100 MHz. 0x1: ISS_FCLK. must be used if the pixel clock is higher than 100 MHz. | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 7:4 | VBUSM_CIDS | BL MAX VBUSM CIDs The BL module supports up to 16 CIDs/tags. This bit field sets up the maximum number of CIDs/tags that the BL can use. The actual number of CIDs/tags is setup by VBUSM_CIDS + 1. Tag number 0 to VBUSM_CIDS are used. | RW | 0xF |
| 3:1 | VBUSM_CPRIORITY | BL VBUSM priority setting 0x6: Normal Priority VBUSM cpriority[2:0] = 6 0x1: High Priority VBUSM cpriority[2:0] = 1 0x7: Normal Priority VBUSM cpriority[2:0] = 7 0x0: High Priority VBUSM cpriority[2:0] = 0 0x2: Medium Priority VBUSM cpriority[2:0] = 2 0x4: Normal Priority VBUSM cpriority[2:0] = 4 0x5: Normal Priority VBUSM cpriority[2:0] = 5 0x3: Medium Priority VBUSM cpriority[2:0] = 3 | RW | 0x4 |
| 0 | OCP_WRNP | ISP OCP master port non-posted write control. 0x0: All writes are non posted. 0x1: All writes are posted. | RW | 0 |

| 9 | RSZB_CLK_EN | Resizer B clock enable This bit enable to enable / disable the RESIZER B clock. Note that it is a second level clock enable. This bit has effect only if RSZ_GCK_SDR is set to 1. 0x0: off 0x1: on | RW | 0 |
| 8 | RSZA_CLK_EN | Resizer A clock enable This bit enable to enable / disable the RESIZER A clock. Note that it is a second level clock enable. This bit has effect only if RSZ_GCK_SDR is set to 1. 0x0: off 0x1: on | RW | 0 |
| 7:1 | RESERVED | | R | 0x00 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|--------------------------------------------------------------------------|------|-------|
| 0 | AUTOGATING | Internal Clock Gating Strategy Enables or disables auto clock gating. | RW | 1 |

NOTE: This is only for debug purposes. When this bit is set to "0" autogating is not performed on any of the clocks, thus the clocks stay free running. Though, they are still controlled by the clock enable bit fields RSZA_CLK_EN and RSZB_CLK_EN.

0x0: Clocks are free running
0x1: Automatic clock gating strategy.

| 15:0 | RSZ_FRACDIV | Fractional clock divider value. The fractional clock divider gates the read requests made to the input data buffer such that the input data buffer is read at an average frequency equal to FFCLK instead of FCLK. The value of FFCLK depends upon the upscaling ratios as well as the input pixel clock: see the functional spec. We have $FFCLK = FCLK / FRACDIV$ MHz and $RSZ_FRACDIV = 65536 / FRACDIV$. When $RSZ_FRACDIV = 65536$, we have: $FFCLK = FCLK$. | RW | 0xFFFF |

| 15:0 | HPS | Horizontal Start Position The RSZ_SRC_HPS register has two functions: The first function is to compensate for possible delay between the HD pulse and the first valid data. It is possible for this delay to be different than 0 when the RESIZER module gets its input data from the VP connected to the IPIPEIF module (the offset value can be odd or even). When data are coming from the IPIPE module, it is not required to resynchronize HD and the first valid data. The second function is to crop the data in the horizontal direction. When used for cropping, only RSZ_SRC_HPS must be even or null. | RW | 0x0000 |

| 31:16 | RESERVED | | R | 0x0000 |
| 15:0 | RZA | Sets the minimum interval btw two consecutive memory request for resizer #A. Specified in number of interface clock cycles. Values of 0, 1, and 2 are used as a condition to keep the bandwidth limiter off. When this function is enabled, this value must be greater than 10 cycles. | RW | 0x0000 |

| Physical Address | 0x5201 0524 | | |
| Description | RESIZER B - INITIAL LUMINANCE PHASE OF VERTICAL RESIZING PROCESS When YUV4:2:2 data are output, the phase values for luma and chroma should typically be equal, that is, RZX_V_PHS_Y= RZX_V_PHS_C. The following constraints apply when setting the initial vertical phases ABS(RZX_V_PHS_Y - RZX_V_PHS_C) RZX_V_DIF. This constraint means that at most the distance between the initial phases for luminance and chrominance is not expected to exceed the distance between two luma pixels. Note that the absolute value is used, hence, the initial luma phase can be greater than the initial chroma phase or the other way around. As a reminder, the distance between two output pixels for luma is given by RZX_V_DIF. | | |

| 31:17 | RESERVED | | R | 0x0000 |
| 16:0 | Y_OFT | Memory Line Offset Sets the size of each line in the circular buffer. It is expressed in bytes and unsigned. Note that OFT does not necessary corresponds to the size of a line in a frame, it can be much bigger. The line offset must be a multiple of 128 bytes (bits [6:0] of RZX_SDR_Y_OFT and RZX_SDR_C_OFT must be set to 0). Example: line 0 address = SAD line 1 address = SAD + 1 x OFT line 2 address = SAD + 2 x OFT | RW | 0x00000 |

| Address Offset | 0x0000 02C8 | Instance | ISS_IPIPE |
| Physical Address | 0x5201 0AC8 | | |
| Description | <p>YUV4:2:2 down sampling register.</p> <p>This register controls the YUV4:4:4 to YUV4:2:2 chroma downsampling. This register is valid if <code>IPIPE_SRC_FMT.FMT = 0</code> (RAW input and YUV output).</p> <p><code>IPIPE_YUV_PHS = 0</code> leads to pure subsampling, no filtering, cosited chroma output.</p> <p><code>IPIPE_YUV_PHS = 1</code> leads to (1, 1) >> 1 filtering, centered chroma output.</p> <p><code>IPIPE_YUV_PHS = 2</code> leads to (1, 2, 1) >> 1 filtering, cosited chroma output.</p> <p><code>IPIPE_YUV_PHS = 3</code> leads to (1, 3, 3, 1) >> 3 filtering, centered chroma output.</p> <p>When the chroma output is cosited, and that downsampling is enabled in the RESIZER module, one needs to take care that the averager disrupts the relative phase for luma and chroma color components. The <code>RZA_H_PHS_ADJ</code> and <code>RZB_H_PHS_ADJ</code> registers need to be used to fix the disruption.</p> | | |

| 1 | LPF | <p>121-LPF enable for chrominance samples.</p> <p>This register is valid if <code>IPIPE_SRC_FMT.FMT = 0</code> (RAW input and YUV output).</p> <p>0x0: off</p> <p>0x1: on</p> | RW | 0 |
| 0 | POS | <p>This bit sets the output position of the chrominance sample with regards to the luma sample positions. One can choose between centered and cosited.</p> <p>This register is valid if <code>IPIPE_SRC_FMT.FMT = 0</code> (RAW input and YUV output).</p> <p>The RESIZER module does not change the relative position of the chroma samples vs. the luma samples between the input and output and the chroma position at the output of the IPIPE module and at the output of the RESIZER module must be identical. In other words, we must have <code>RSZ_YUV_PHS.POS = IPIPE_YUV_PHS.POS</code>.</p> <p>0x0: Cosited = same position with luminance</p> <p>0x1: Centered = middle of the luminance</p> | RW | 0 |

| 15:2 | RESERVED | | R | 0x0000 |
| 1 | CLR | Histogram memory clear. The histogram can be cleared before the start of operations. However, the clear takes 512 cycles and therefore: + if line size > 512, the first line must not be used for histogram computation. + if line size < 512, ceil (512/line size) lines must not be used for histogram computation. It's the programmer's responsibility to set the histogram computation area outside the "clear" area. 0x0: Disable 0x1: Enable | RW | 0 |
| 0 | SEL | This bit must be used to select which memory is used to store the histogram data. By selecting alternatively one or the other bit, one can double buffer the histogram output buffer. The 4 KB memory can either be read by the CPU or a DMA request. 0x0: Use Table 0 and 1 = 4KB in the memory ISP map. 0x1: Use Table 2 and 3 = 4KB in the memory ISP map. | RW | 0 |

| 15:2 | RESERVED | | R | 0x0000 |
| 1 | DWEN | Controls the storage of image sensor RAW data in memory. This bit is loaded with the timing of the internal VD signal: it becomes active starting at the lead of the VD signal that comes after 1 is written in this bit. 0x0: Disable 0x1: Enable | RW | 0 |
| 0 | SYEN | Controls ON/OFF of VD/HD output. Internal timing generator becomes active and VD/HD output starts when 1 is written in this bit. In case of input, VD/HD loading begins. 0: Disable 1: Enable | RW | 0 |

| 31:16 | RESERVED | | R | 0x0000 |
| 15 | RESERVED | Read returns reset value | R | 0 |
| 14 | HLPF | Low pass filter enable. When this bit is enabled, a 3-tap ($1/4 + 1/2 Z^{-2} + 1/4 Z^{-4}$) filtering process is performed on the sensor data. 0x0: Disable 0x1: Enable | RW | 0 |
| 13:12 | INPMOD | Data input mode: 0x0: RAW data 0x1: YCbCr 16bit 0x3: Reserved 0x2: YCbCr 8bit | RW | 0x2 |
| 11 | OVF | ISIF module write port overflow status bit If the write port of the ISIF module overflows when writing data to SDRAM, this bit will toggle. 0x0: No overflow pending (r) No action (w) 0x1: Overflow pending (r) Clear overflow (w) | RW | 0 |
| 10:8 | CCDW | This bit enables to shift right (divide) the up-to-12-bit RAW data value when writing out to SDRAM. The effect is that the dynamic of the output signal is decreased. The ISIF_MODESET.CCDW , ISIF_HSIZE.ADCR , ISIF_HSIZE.HSIZE , ISIF_CCDCFG.BSWD , ISIF_CCDCFG.MSBINV , ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x6: Reserved 0x1: 1-bit right shift out[15:0] = 00000 & data[11:1] 0x7: Reserved 0x0: No shift out[15:0] = 0000 & data[11:0] 0x2: 2-bit right shift out[15:0] = 000000 & data[11:2] 0x4: 4-bit right shift out[15:0] = 00000000 & data[11:4] 0x5: Reserved 0x3: 3-bit right shift out[15:0] = 0000000 & data[11:3] | RW | 0x0 |
| 7 | CCDMD | Field mode: This bit selects the type of image sensor: interlaced or progressive 0x0: Progressive image sensor 0x1: Interlaced image sensor | RW | 0 |
| 6 | DPOL | Image sensor input data polarity 0x0: No change 0x1: One's complement | RW | 0 |
| 5 | SWEN | External WEN selection In case this bit and SYNCEN.DWEN are set to 1, the external WEN signal is used to store image sensor data to memory. 0x0: WEN not used 0x1: Use external WEN | RW | 0 |
| 4 | RESERVED | Read returns reset value | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 3 | HDPOL | HD Sync Signal Polarity 0x0: Positive 0x1: Negative | RW | 0 |
| 2 | VDPOL | VD Sync Signal Polarity 0x0: Positive 0x1: Negative | RW | 0 |
| 1 | FIDD | FLD Signal Direction. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for the start of frame comes. 0x0: Input 0x1: Output | RW | 0 |
| 0 | HDVDD | VD,HD Sync Signal Direction. There must be at least three clock cycles between the time this bit is modified and the HD/VD pulse for the start of frame comes. 0x0: Input 0x1: Output | RW | 0 |

| 15:13 | RESERVED | | R | 0x0 |
| 12 | ADCR | SDRAM address decrement. By setting this bit, memory address in a line is automatically decreased so that a line can be Horizontally flipped in memory. The ISIF_MODESET.CCDW , ISIF_HSIZE.ADCR , ISIF_HSIZE.HSIZE , ISIF_CCDCFG.BSWD , ISIF_CCDCFG.MSBINV , ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: Address increment. 0x1: Address decrement. | RW | 0 |
| 11:0 | HSIZE | Memory address offset between the lines. Specify the offset in 32-byte units. | RW | 0x000 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:16 | RESERVED | | R | 0x0000 |
| 15 | VLDC | On/off control of CPU registers resynchronize function by VSYNC. All the others are shadowed registers, where register values are updated at V-sync timing by default. If VDLC=1, ISIF register values are updated immediately after register write just like non-shadowed registers. 0x0: Enable 0x1: Disable | RW | 0 |
| 14 | RESERVED | Reserved. must always be set to 0. | RW | 0 |
| 13 | MSBINVI | MSB inverse of CIN port when the data are captured to SDRAM. The ISIF_MODESET.CCDW , ISIF_HSIZE.ADCR , ISIF_HSIZE.HSIZE , ISIF_CCDCFG.BSWD , ISIF_CCDCFG.MSBINV , ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: Disable 0x1: Enable | RW | 0 |
| 12 | BSWD | On/off control of Byte SWAP function when SDRAM capturing. The ISIF_MODESET.CCDW , ISIF_HSIZE.ADCR , ISIF_HSIZE.HSIZE , ISIF_CCDCFG.BSWD , ISIF_CCDCFG.MSBINV , ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: Disable 0x1: Enable (swap) | RW | 0 |
| 11 | Y8POS | Selects Y signal position when in 8bit input mode 0x0: even pixel 0x1: odd pixel | RW | 0 |
| 10 | EXTRG | Setting 1 to this register, the SDRAM address is initialized at the rising edge of FID input signal or DWEN register. | RW | 0 |
| 9 | TRGSEL | Select trigger source signal of SDRAM address initializing in case EXTRG=1. 0x0: DWEN register 0x1: FID input port | RW | 0 |
| 8 | WENLOG | Specifies the CCD valid area. 0x0: internal valid signal and WEN signal is ANDed logically. 0x1: internal valid signal and WEN signal is ORed logically. | RW | 0 |
| 7:6 | FIDMD | Specifies FID detection mode 0x0: latch the FID at the VSYNC timing 0x1: no latch the FID 0x3: Reserved 0x2: Reserved | RW | 0x0 |
| 5 | BT656 | Selects bit width of CCIR656. This bit applies only if ISIF_REC656IF.R656ON = 1. 0x0: 8 bits 0x1: 10 bits | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 4 | YCINSWP | The ISIF module has a 16-bit interface. When 16-bit YUV data are input, the luma data (YIN7-0) are expected to be on the 8 MS bits and the chroma (CIN7-0) data are expected to be on the LS bits. This bit enables to swap the 8 MS bits with the 8 LS bits of the interface in case the luma and chroma do not come in the correct order. See the top-level ISIF block diagram. 0x0: YIN7-0 = Y signal / CIN7-0 = C signal 0x1: YIN7-0 = C signal / CIN7-0 = Y signal | RW | 0 |
| 3 | RESERVED | Reserved. must always be set to 0. | RW | 0 |
| 2 | RESERVED | Reserved. must always be set to 0. | RW | 0 |
| 1:0 | SDRPACK | This bit field selects how the data are stored to SDRAM. There can be 8, 12 or 16 bits per pixel. The ISIF_MODESET.CCDW , ISIF_HSIZE.ADCR , ISIF_HSIZE.HSIZE , ISIF_CCDCFG.BSWD , ISIF_CCDCFG.MSBINV , ISIF_CCDCFG.SDRPACK bit fields control how pixel data are stored to SDRAM. 0x0: 16 bits / pixel 0x1: 12 bits / pixel 0x3: Reserved 0x2: 8 bits / pixel | RW | 0x0 |

| RESERVED | | | | | | | | | | | | | | | | SYNCOFF | | ENABLE | | | | | | | | | | | | | |

| Bits | Field Name | Description | Type | Reset |
|------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------------|
| 31:2 | RESERVED | | R | 0x0000 0000 |
| 1 | SYNCOFF | VD output mask This register masks the VD output to the IPIPE module. This can be useful when one wants to read data from SDRAM which are stored in a double buffer. If the VD is not masked each time we start the module an new VD will be generated to the IPIPEIF module. Let's consider two buffers A and B of N lines each. *This bit field is latched by VD. 0x0: VD output mask is disabled. 0x1: VD output mask is enabled. | RW | 0 |
| 0 | ENABLE | IPIPE I/F Enable This register is used to start the operation of SDRAM buffer memory read and generates SYNC signals. This register is available when INPSRC1 or INPSRC2 = 1, 2 or 3. 0x0: disable 0x1: enable | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|--------|
| 31:16 | RESERVED | | R | 0x0000 |
| 15:14 | INPSRC1 | Selects the source for the mux (VPORT / ISIF / SDRAM) as well as the data format type. 0x0: VPORT_RAW 0x1: SDRAM_RAW 0x3: SDRAM_YUV 0x2: ISIF_DARKFM Input ports to DFS submodule are ISIF and SDRAM. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 13:11 | DATASFT | SDRAM read data shift This register is available when INPSRC1 or INPSRC2 = 1 or 2, that is, when data are read from SDRAM. 0x6: Output data[11:0] = (read data[15:4] >> 4) & 0x0FFF 0x1: Output data[11:0] = (read data[11:0] << 1) & 0x0FFF 0x7: Output data[11:0] = (read data[15:4] >> 4) & 0x0FFF 0x0: Output data[11:0] = (read data[11:0]) & 0x0FFF 0x2: Output data[11:0] = (read data[11:0] << 2) & 0x0FFF 0x4: Output data[11:0] = (read data[11:0] << 4) & 0x0FFF 0x5: Output data[11:0] = (read data[15:4] >> 4) & 0x0FFF 0x3: Output data[11:0] = (read data[11:0] << 3) & 0x0FFF | RW | 0x0 |
| 10 | CLKSEL | IPIPEIF and IPIPE module pixel clock selection. This register must be set to 1 when INPSRC1 or INPSRC2 = 1 or 3, that is, data are solely read from SDRAM (VPORT inactive). 0x0: Selects the pixel clock from the VPORT. 0x1: Selects the pixel clock from the fractional clock divider. The fractional clock divider value is setup with the IPIPEIF_CLKDIV register. | RW | 0 |
| 9:8 | UNPACK | 8-Bit, 12-bit Packed Mode When sensor raw data are stored in 8-bit packed mode or 12-bit packed mode, this register should code 1 or 3. This register is effective when INPSRC = 1 or 2. 0x0: 16 bits / pixel 0x1: 8 bits / pixel 0x3: 12 bits / pixel 0x2: 8 bits / pixel + inverse A law (8 bits to 10 bits) | RW | 0x0 |
| 7 | AVGFILT | Averaging Filter It applies (1,2,1) filter for the RGB/YCbCr data. *This bit field is latched by VD. 0x0: disable 0x1: enable | RW | 0 |
| 6:4 | RESERVED | | R | 0x0 |
| 3:2 | INPSRC2 | Selects the source for the mux (ISIF / SDRAM) as well as the data format type. 0x0: ISIF 0x1: SDRAM_RAW 0x3: SDRAM_YUV 0x2: ISIF_DARKFM Input ports to DFS submodule are VPORT and SDRAM. | RW | 0x0 |
| 1 | DECIM | Pixel Decimation The decimation rate defined by RSZ register. *This bit field is latched by VD. 0x0: No decimation 0x1: Decimation | RW | 0 |
| 0 | ONESHOT | One Shot Mode This register is available when INPSRC = 1 or 3. 0x0: Continuous mode 0x1: One shot mode | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:22 | AVE2LMT | AE/AWB Saturation Limit This is the value that all sub sampled pixels in the AE/AWB engine are compared to. If the data is greater or equal to this data then the block is considered saturated. | RW | 0x3FF |
| 21 | OVF | H3A module overflow status bit. If the H3A module overflows it will keep sending data. The software can read this status bit during vertical blanking period to ensure that no overflow happened while writing out the data to SDRAM. There is also an interrupt at ISP level (H3A_OVF) which can be used to monitor this. 0x0: Read 0: No overflow pending Write 0: Status bit unchanged 0x1: Read 1: Overflow happened while writing out the data. Output data likely to be corrupted. Write 1: Clear the status bit. | RW | 0 |
| 20 | AF_VF_EN | AF Vertical Focus Enable 0x0: 4 Color Horizontal FV only 0x1: 1 Color Horizontal FV and 1 Color Vertical FV | RW | 0 |
| 19 | AEW_MED_EN | AE/AWB Median filter Enable If the median filter is enabled, then the 1st 2 and last 2 pixels in the frame are not filtered. 0x0: Disable Auto Focus median filter 0x1: Enable Auto Focus median filter | RW | 0 |
| 18 | BUSYAEAWB | Busy bit for AE/AWB | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 17 | AEW_ALAW_EN | AE/AWB A-law Enable 0x0: Disable Auto exposure/white balance A-law table 0x1: Enable Auto exposure/white balance A-law table. | RW | 0 |
| 16 | AEW_EN | AE/AWB enable 0x0: Disable Auto exposure/white balance 0x1: Enable Auto exposure/white balance | RW | 0 |
| 15 | BUSYAF | Busy bit for AF. | R | 0 |
| 14 | FVMODE | Focus Value Accumulation Mode 0x0: Sum mode. 0x1: Peak mode. | RW | 0 |
| 13:11 | RGBPOS | Red, Green, and blue pixel location in the AF windows RGBPOS(0): GR and GB as Bayer pattern RGBPOS(1): RG and GB as Bayer pattern RGBPOS(2): GR and BG as Bayer pattern RGBPOS(3): RG and BG as Bayer pattern RGBPOS(4): GG and RB as custom pattern RGBPOS(5): RB and GG as custom pattern 6 and 7 are reserved This Value is only used if VF is disabled | RW | 0x0 |
| 10:3 | MED_TH | Median filter threshold. | RW | 0xFF |
| 2 | AF_MED_EN | Auto Focus Median filter Enable If the median filter is enabled, then the 1st 2 and last 2 pixels in the frame are not in the valid region. Therefore the paxel start/end and IIR filter start positions should not be set within the 1st and last 2 pixels. 0x0: Disable AF median filter. 0x1: Enable AF median filter. | RW | 0 |
| 1 | AF_ALAW_EN | AF A-law table enable 0x0: Disable Auto Focus A-law table 0x1: Enable Auto Focus A-law table | RW | 0 |
| 0 | AF_EN | AF enable 0x0: Disable Auto Focus Engine 0x1: Enable Auto Focus Engine | RW | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:21 | RESERVED | | R | 0x000 |
| 20:17 | AFINCH | AF Engine Column Increments Number of columns to increment in a poxel plus 1 multiplied by 2. Thus, the number of columns that can be skipped between two processed line pairs is 2-32 (even). The starting two columns in a poxel are first processed before this field is applied. This must be set so that there are at least 4 samples on a line when combined with the number of horizontal paxels. * This value is shadowed and latched on the rising edge of VSYNC. | RW | 0x0 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 16:13 | AFINCV | AF Engine Line Increments Number of lines to increment in a Poxel plus 1 multiplied by 2. Incrementing the line in a paxel is always done on a line pair due to the fact that the RGB pattern falls in two lines. If all the lines are to be processed, this field should be set to zero, and thus line count is incremented by 2 following a line pair. Thus, the number of lines that can be skipped between two processed line pairs is 0-30 (even). The starting two lines in a paxel are first processed before this field is applied. * This value is shadowed and latched on the rising edge of VSYNC. | RW | 0x0 |
| 12:6 | PAXVC | AF Engine Vertical Poxel Count The number of paxels in the vertical direction plus 1. The maximum number of vertical paxels in a frame should not exceed 128. The value should be set to ensure that the bandwidth requirements and buffer size are not exceeded. * This value is shadowed and latched on the rising edge of VSYNC. | RW | 0x00 |
| 5:0 | PAXHC | AF Engine Horizontal Poxel Count The number of paxels in the horizontal direction plus 1. It is illegal to set a number that is greater than 35 (total of 36 paxels in the horizontal direction). The minimum number of paxels should be 2 (valid range for the field is 1-35). * This value is shadowed and latched on the rising edge of VSYNC. | RW | 0x00 |

| Bits | Field Name | Description | Type | Reset |
|-------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 31:24 | WINH | AE/AWB Engine Window Height This specifies the window height in an even number of pixels, the window height is the value plus 1 multiplied by 2. The final value can be from 2-512 (even) * This value is shadowed and latched on the rising edge of VSYNC. | RW | 0x00 |
| 23:21 | RESERVED | | R | 0x0 |
| 20:13 | WINW | AE/AWB Engine Window Width This specifies the window width in an even number of pixels, the window width is the value plus 1 multiplied by 2. The minimum width is 16 pixels if the pixel clock is half or less of the ISS_FLCK clock. If the pixel clock is equal to the ISS_FLCK clock, the minimum width is 32 pixels. * This value is shadowed and latched on the rising edge of VSYNC. | RW | 0x00 |
| 12:6 | WINVC | AE/AWB Engine Vertical Window Count The number of windows in the vertical direction plus 1. The maximum number of vertical windows in a frame should not exceed 128. The value should be set to ensure that the bandwidth requirements and buffer size are not exceeded * This value is shadowed and latched on the rising edge of VSYNC. | RW | 0x00 |
| 5:0 | WINHC | AE/AWB Engine Horizontal Window Count The number of horizontal windows plus 1. The maximum number of horizontal windows is 35 plus 1 (36). The minimum number of windows should be 2 (valid range for the field is 1-35). * This value is shadowed and latched on the rising edge of VSYNC. | RW | 0x00 |

8.4 ISS Still Image Coprocessor

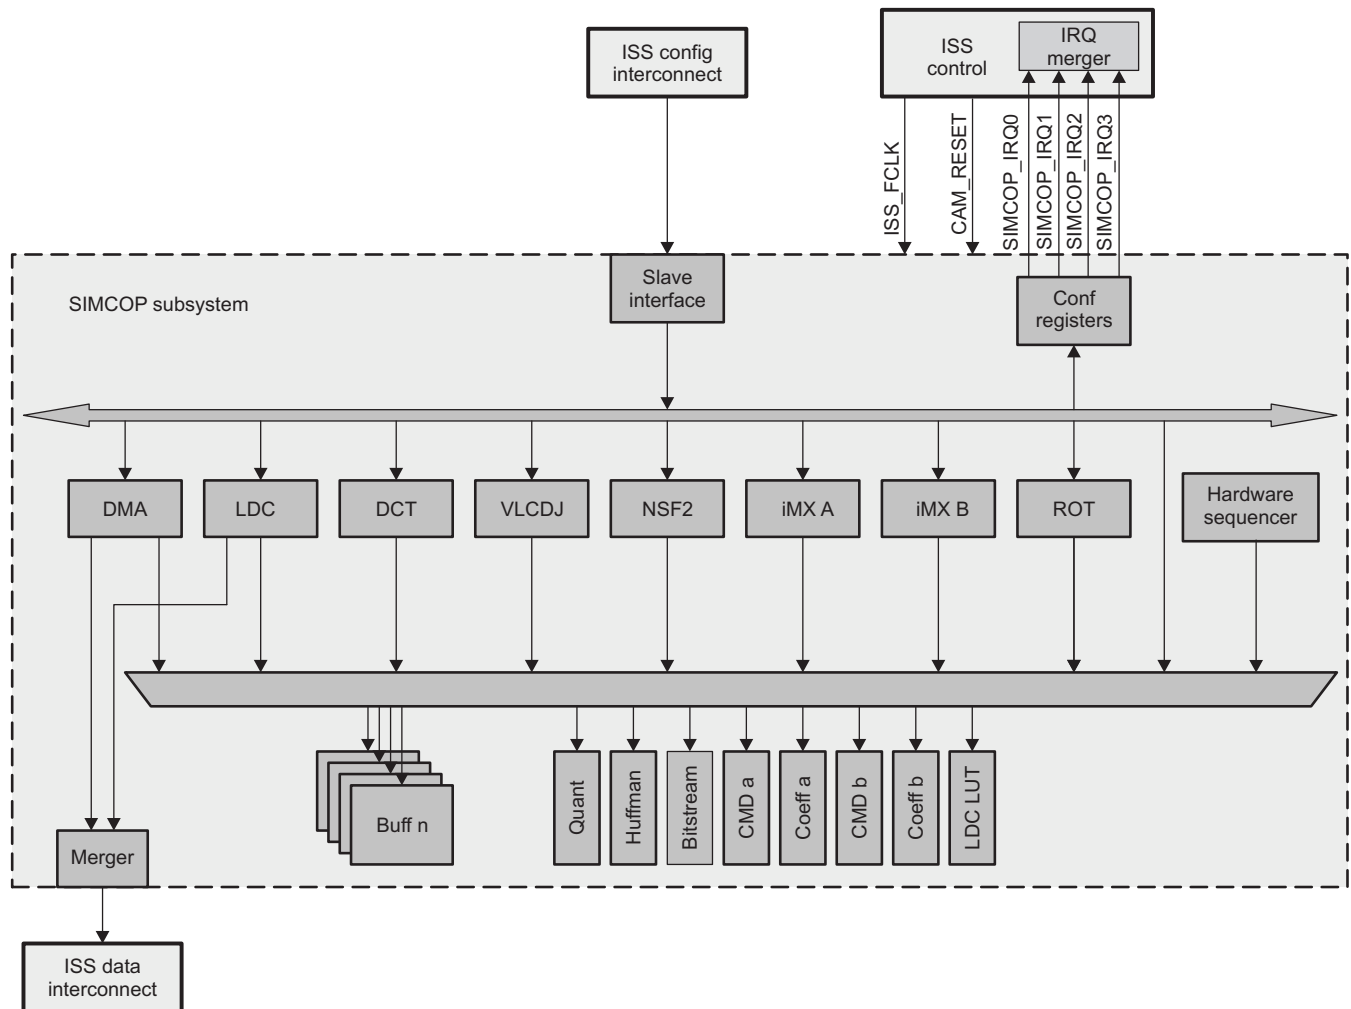

This section gives a high-level description of the ISS still iMage coprocessor (SIMCOP) in the device. For a high-level description of ISS level, see [Section 8.1](#), *ISS:Overview*.

8.4.1 ISS SIMCOP Overview

The SIMCOP subsystem is designed to encode, decode, and process image data. The SIMCOP is a macroblock-based memory-to-memory processing engine. It fetches macroblocks from system memory and stores them into local memories. Different accelerators take the fetched data, perform processing, and send the processing outcome back to local memories. From there the data could be further processed by other accelerators or be sent back to system memory. The SIMCOP needs an external central processing unit (CPU) to perform high-level control tasks and configurations. The SIMCOP is closely coupled to a CPU for that purpose.

[Figure 8-239](#) shows a block diagram of the SIMCOP subsystem.

Figure 8-239. SIMCOP Subsystem Overview

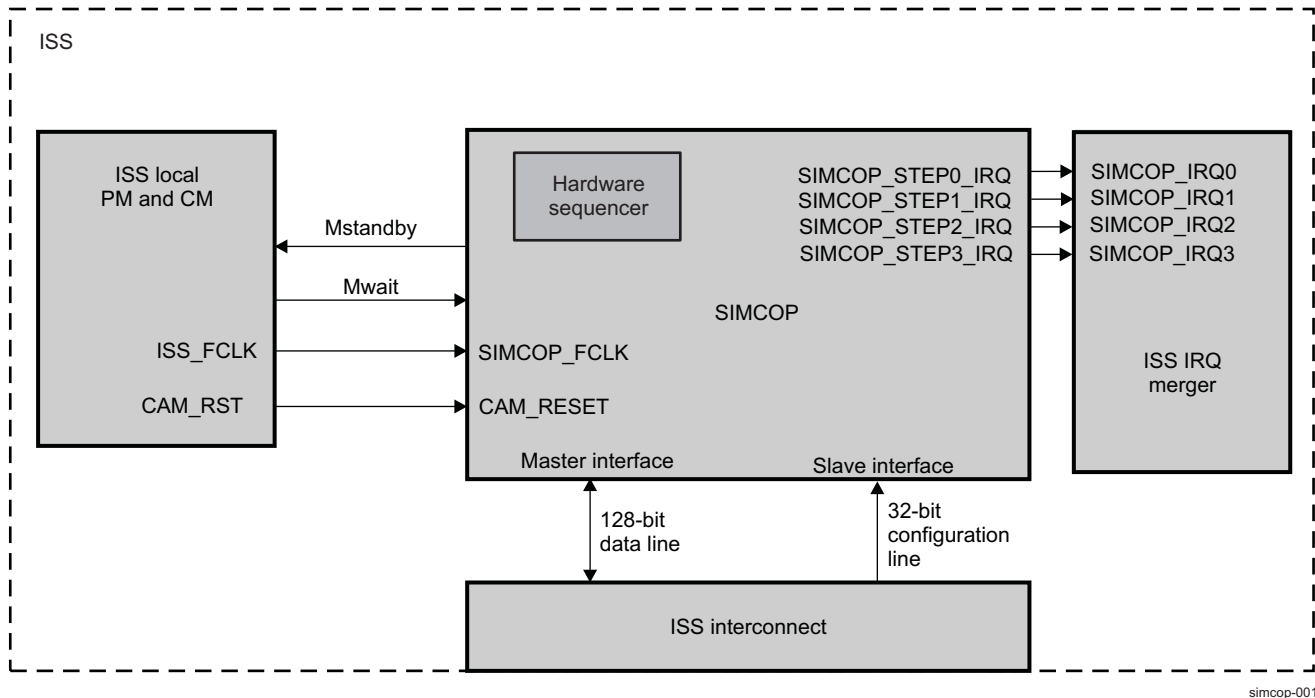

simcop-002

The ISS SIMCOP subsystem consists of:

- Noise filter (NSF2) for advanced noise filtering and an edge-enhancement
- Two image and video processing engines (iMXs) supplement various fixed-function processing blocks
- Variable-length coder/decoder for JPEG (VLCDJ) module handles quantization and variable length coding, decoding and inverse quantization
- Discrete cosine transform (DCT) module implements method in the compression flow to transform blocks of image
- Lens distortion correction (LDC) module deals with lens geometric distortion issues in the camera subsystem
- Rotation accelerator (ROT) engine blocks data rotation and shifting from a SIMCOP local memory to another SIMCOP local memory
- Hardware sequencer and buffers control SIMCOP modules/buffers to offload an external processor to perform low-level sequencing tasks
- Direct memory access (DMA) controller data transfers from SIMCOP memories to system memory or from system memory to SIMCOP memories

8.4.1.1 ISS SIMCOP Integration

The SIMCOP subsystem is connected to the rest of the system through the ISS local interconnect. Figure 8-240 shows the integration of the SIMCOP subsystem in the ISS.

Figure 8-240. SIMCOP Integration

simcop-001

NOTE: For more information about the IDLE hardware handshake and the wake-up request, see [Section 3.1.1.1, Clock Management](#), in [Chapter 3, Power, Reset, and Clock Management](#).

This section gives an overview of typical uses of the module. See [Chapter 3, Power, Reset, and Clock Management](#), for more information and settings of the PRCM relationship to ISS clocks and resets.

[Table 8-1232](#) lists the integration attributes.

Table 8-1232. Integration Attributes

| Module Instance | Attributes | |
|-----------------|--------------|--------------|
| | Power Domain | Interconnect |
| SIMCOP | PD_CAM | |

[Table 8-1233](#) lists the clocks and resets values.

Table 8-1233. Clocks and Resets

| Clocks | | | | |
|-----------------|-------------------------|--------------------|--------|--------------------------------------------------------------------------------------------------------------------------|
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SIMCOP | SIMCOP_FCLK | ISS_FCLK | PRCM | Functional clock provided by ISS_CLK from the PRCM module. It is used by all ISS submodules and ISS top-level resources. |
| Resets | | | | |
| Module Instance | Destination Signal Name | Source Signal Name | Source | Description |
| SIMCOP | CAM_RESET | CAM_RST | PRCM | ISS and SIMCOP global reset |

Table 8-1234 lists the hardware resets.

Table 8-1234. Hardware Requests

| Interrupt Requests | | | | |
|--------------------|--------------------|-------------------------|-------------------|------------------------------------------------------------------------------|
| Module Instance | Source Signal Name | Destination Signal Name | Destination | Description |
| SIMCOP | SIMCOP_STEP_0_IRQ | SIMCOP_IRQ0 | SIMCOP IRQ merger | Event triggered when a SIMCOP context is activated by the hardware sequencer |
| SIMCOP | SIMCOP_STEP_1_IRQ | SIMCOP_IRQ1 | SIMCOP IRQ merger | Event triggered when a SIMCOP context is activated by the hardware sequencer |
| SIMCOP | SIMCOP_STEP_2_IRQ | SIMCOP_IRQ2 | SIMCOP IRQ merger | Event triggered when a SIMCOP context is activated by the hardware sequencer |
| SIMCOP | SIMCOP_STEP_3_IRQ | SIMCOP_IRQ3 | SIMCOP IRQ merger | Event triggered when a SIMCOP context is activated by the hardware sequencer |

For more information about interrupt requests, see [Section 8.4.1.2.3, Interrupt Merger](#).

8.4.1.2 ISS SIMCOP Functional Description

8.4.1.2.1 ISS SIMCOP Local Power and Clock Management

8.4.1.2.1.1 ISS SIMCOP Local Clock Management

ISS has five asynchronous clock domains. The SIMCOP belongs to the ISS_FCLK clock domain.

An externally provided clock-enable signal is used. Multiple subdomains exist internally to reduce dynamic power consumption. This feature does not require intervention by the PRCM module. For high-level description of the SIMCOP clock domain and configuration inside ISS, see [Section 8.1.2.2, ISS Clocks](#).

Moreover, at high level the functional clock of ISS SIMCOP submodules can be cut by software to reduce power consumption by cutting off or turning on the modules from the [SIMCOP_CLKCTRL](#) register (see [Table 8-1235](#)).

When software wants to enable a submodule:

- Software sets the adequate bit in the [SIMCOP_CLKCTRL](#) register.
- Hardware enables the submodule functional and interface clocks.
- Hardware connects the configuration port of the submodule to the coprocessor bus.
- Hardware sets the appropriate bit in the [SIMCOP_CLKCTRL](#) register. Software must check if this bit is set before accessing the submodule.

[Table 8-1235](#) lists the ISS SIMCOP clock control register settings.

Table 8-1235. ISS SIMCOP Clock Control Register Settings

| Module Name | Bit Field Name | Description |
|-------------|------------------------------------------|--------------------------------|
| ROT | SIMCOP_CLKCTRL [7] ROT_A | Writing 0x1 enables the module |
| iMX B | SIMCOP_CLKCTRL [6] IMX_B | Writing 0x1 enables the module |
| iMX A | SIMCOP_CLKCTRL [5] IMX_A | Writing 0x1 enables the module |
| NSF2 | SIMCOP_CLKCTRL [4] NSF2 | Writing 0x1 enables the module |
| VLCDJ | SIMCOP_CLKCTRL [3] VLCDJ | Writing 0x1 enables the module |
| DCT | SIMCOP_CLKCTRL [2] DCT | Writing 0x1 enables the module |
| LDC | SIMCOP_CLKCTRL [1] LDC | Writing 0x1 enables the module |
| DMA | SIMCOP_CLKCTRL [0] DMA | Writing 0x1 enables the module |

When software wants to shutdown a submodule:

- Software ensures that the submodule is idle. Mainly:
 - The submodule must not generate new events.
 - The submodule must not have any pending events.
 - For initiators: the submodule must stop interconnect transaction generation.
- Software clears the appropriate bit in the [SIMCOP_CLKCTRL](#) register.
- Hardware disconnects the configuration port of the module from the coprocessor bus: no more accesses are routed to the submodule. Ongoing transactions are finished (hardware stays in this state as long as required).
- For initiators: hardware waits until there are no more outstanding transactions:
 - SIMCOP DMA provides an MStandBy signal for that purpose.
 - The LDC does not provide this information. Software must ensure that the LDC is idle. SIMCOP hardware ensures that the internal MTC2OCP bridges have no outstanding transactions.
- Hardware cuts the submodules clock.
- Hardware clears the appropriate [SIMCOP_CLKCTRL](#) registers.

SIMCOP submodules support autogating. They can gate their functional and interface clock internally based on functional requirements. This feature could be disabled for debug or power consumption measurement purposes.

8.4.1.2.1.2 Local Clock Autogating

The SIMCOP subsystem modules support autogating. They can gate their functional and interface clock internally based on functional requirements. This feature can be disabled. [Table 8-1236](#) summarizes which modules support autogating control and which control bit is used.

Table 8-1236. Autoclock Gating Bit Control

| SIMCOP Resource | Autogating Override |
|----------------------------|------------------------------|
| SIMCOP top-level resources | N/A |
| SIMCOP DMA | N/A |
| LDC | N/A |
| DCT | DCT_CFG[5] AUTOGATING |
| VLCDJ | VLCDJ_CTRL[3] AUTOGATING |
| NSF2 | N/A |
| iMX A | iMXa.IMX_CLKCNTRL[0] CLKCNTL |
| iMX B | iMXb.IMX_CLKCNTRL[0] CLKCNTL |
| ROT | ROT_CFG[9] AUTOGATING |

8.4.1.2.1.3 ISS SIMCOP Power Management

The SIMCOP supports the STANDBY power-management protocol. It is used by the SIMCOP to indicate when it has no more interconnect transactions to perform. This information is used at ISS level to control the SIMCOP and ISS shut-down sequence. The SIMCOP does not have any internal wake-up events. DISCONNECT and IDLE protocols are not supported.

The typical SIMCOP shut-down sequence is:

1. Software disables all SIMCOP submodules. This ensures the SIMCOP does not:
 - (a) Generate any traffic on its master port: SIMCOP asserts the MStandby signal.
 - (b) Generate new events (IRQs).
2. Software clears all pending events at SIMCOP level: All interrupt lines become inactive.
3. Software initiates the SIMCOP shut-down sequence by writing the appropriate bit at ISS level.
4. ISS hardware:

- (a) Disconnects the SIMCOP configuration port. Any access attempts to SIMCOP are blocked at ISS level. The DISCONNECT protocol is handled at ISS level: SIMCOP does not provide any handshake signals to support it.
- (b) Waits until MStandby from SIMCOP is asserted (always true in a normal case because SIMCOP submodules are inactive)
- (c) Asserts the SWait input of SIMCOP
- (d) Cuts the SIMCOP clock

The typical SIMCOP enable sequence is:

1. Software initiates the SIMCOP enable sequence by writing the appropriate bit at ISS level.
2. ISS hardware:
 - (a) Enables the SIMCOP clock
 - (b) Deasserts the SWait input of the SIMCOP
 - (c) Connects the SIMCOP configuration port

Three modes for MStandBy control are supported. The mode is selected using the [SIMCOP_HL_SYSCONFIG\[5:4\] STANDBYMODE](#) bit field.

- Smart-standby: This is the normal mode to be used. When in this mode, the SIMCOP asserts the MStandBy signal when the MStandBy output of SIMCOP DMA is asserted, the LDC is effectively disabled ([SIMCOP_CLKCTRL\[1\] LDC =0](#)), and the MTCR2OCP bridge and the merger have no more outstanding transactions.
- Force-standby: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, the SIMCOP asserts MStandBy unconditionally. Software must ensure that the SIMCOP is in a correct quiet state before programming this mode.
- No-standby: This is a backup mode intended to be used only if smart-idle mode is bugged. When in this mode, the SIMCOP never asserts the MStandBy signal.

8.4.1.2.2 Software Reset

Software reset is intended to return the SIMCOP into a known state without requiring a complete device reset. A software reset at SIMCOP level is seen as a hardware reset for SIMCOP submodules. To perform a software reset, sets the [SIMCOP_HL_SYSCONFIG\[0\] SOFTRESET](#) bit to 1. The [SIMCOP_HL_SYSCONFIG\[0\] SOFTRESET](#) bit indicates that the software reset is ongoing when its value is 1. When the software reset completes, the [SIMCOP_HL_SYSCONFIG\[1\] SOFTRESET](#) bit is automatically reset. Software must ensure that the software reset completes before configuring the hardware sequencer or buffers.

8.4.1.2.3 Interrupt Merger

SIMCOP interrupts are merged at the SIMCOP subsystem level into four interrupts, as shown in [Figure 8-241](#).

Figure 8-241. SIMCOP Interrupt Merger Overview

These four outputs interrupts can be configured through [SIMCOP_HL_IRQENABLE_SET_i](#) and [SIMCOP_HL_IRQENABLE_CLR_i](#) (where i = 0 to 3, corresponding to output interrupt) to enable or disable interrupt mask for each interrupt output. Software can poll the value of interrupt before masking ([SIMCOP_HL_IRQSTATUS_RAW_i](#)) and after masking ([SIMCOP_HL_IRQSTATUS_i](#)).

Software can configure how outputs interrupts are generated through `SIMCOP_CTRL[i] IRQi_MODE` (where $i = 0$ to 3):

- 0x0: OR, the interrupt is asserted when one of the selected events has occurred
 - 0x1: AND, the interrupt is asserted when all selected events have occurred
- [Table 8-1237](#) shows how interrupts are mapped on the `SIMCOP_HL_IRQSTATUS_RAW_i`, `SIMCOP_HL_IRQSTATUS_i`, `SIMCOP_HL_IRQENABLE_SET_i`, and `SIMCOP_HL_IRQENABLE_CLR_i` registers.

Table 8-1237. SIMCOP Interrupts

| Bit | Name | Description |
|-----|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0 | SIMCOP_DMA_IRQ0 | Interrupt triggered by SIMCOP DMA |
| 1 | LDC_FRAME_IRQ | A full frame has been processed by LDC2 |
| 2 | DCT_IRQ | DCT operation has been completed (configured number of MCUs for YUV4:2:0/4:2:2 mode, or number of blocks for sequential block mode). |
| 3 | VLCDJ_BLOCK_IRQ | A macroblock has been processed (encode/decode). |
| 4 | NSF_IRQ | Event triggered by the NSF2 imaging accelerator when processing of a block is done |
| 5 | IMX_A_IRQ | Event triggered when iMX has executed a SLEEP instruction |
| 6 | IMX_B_IRQ | |
| 7 | ROT_A_IRQ | Event triggered by the ROT engine |
| 8 | RESERVED | Reserved |
| 9 | LDC_BLOCK_IRQ | A macroblock has been processed by LDC2. |
| 10 | SIMCOP_STEP0_IRQ | Event triggered when a SIMCOP context is activated by the hardware sequencer |
| 11 | SIMCOP_STEP1_IRQ | |
| 12 | SIMCOP_STEP2_IRQ | |
| 13 | SIMCOP_STEP3_IRQ | |
| 14 | DONE_IRQ | Event triggered when the hardware sequencer finishes the sequence: - the sequence step counter has reached the limit - All accelerator and DMA events for the last sequence step have been received. |
| 15 | VLCDJ_DECODE_ERR_IRQ | A decode error has been signaled by the VLCDJ |
| 16 | ICNT_ERR_IRQ | An error has been received on the SIMCOP master port on the L3 interconnect. |
| 17 | LDC2BRIDGE_ERR_IRQ | The LDC2 bridge has generated an error. This event must not trigger in a normal use case. |
| 18 | SIMCOP_DMA_IRQ1 | Interrupt triggered by SIMCOP DMA |
| 19 | CPU_PROC_START_IRQ | This interrupt is used when CPU data processing is used in a macroblock processing pipeline. When the CPU receives this IRQ, data is ready to be processed. When CPU is done with processing it acknowledges by setting the <code>SIMCOP_HWSEQ_CTRL.CPU_PROC_DONE</code> bit. The interrupt is cleared as usual. |

8.4.1.2.4 ISS SIMCOP Modules Description

This section gives links to each subsection for each submodule in the ISS SIMCOP module.

The ISS module provides unique `ISS_FCLK` for all the submodules inside the SIMCOP (see [Section 8.4.1.2.1.1, ISS SIMCOP Local Clock Management](#)).

For information about hardware and software resets for each module see [Table 8-1237](#).

For interrupt request information for each module, see [Section 8.4.1.2.3, Interrupt Merger](#).

ISS SIMCOP consists of the following submodules:

- Hardware sequencer and buffers, for more information see [Section 8.4.2, ISS SIMCOP Hardware Sequencer and Buffers](#).
- DMA, for more information, see [Section 8.4.3, ISS SIMCOP DMA Module](#).
- ROT, for more information, see [Section 8.4.7, ISS SIMCOP Rotation Accelerator \(ROT\) Module](#).
- iMX
- NSF2

- VLCDJ, for more information, see [Section 8.4.6, ISS SIMCOP Variable Length Coder/Decoder for JPEG \(VLCDJ\) Module](#).
- DCT, for more information, see [Section 8.4.5, ISS SIMCOP Discrete Cosine Transform \(DCT\) Module](#).
- LDC, for more information, see [Section 8.4.4, ISS SIMCOP LDC Module](#).

8.4.1.3 ISS SIMCOP Programming Models

8.4.1.3.1 Global Initialization

8.4.1.3.1.1 Surrounding Modules Global Initialization

This section identifies the requirements of initializing the surrounding modules when the ISS SIMCOP module is to be used for the first time after a device reset. This initialization of surrounding modules is based on the integration of the ISS SIMCOP.

Table 8-1238. Global Initialization of Surrounding Modules

| Surrounding Modules | Comments |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ISS local PM and CM | Module interface and functional clocks must be enabled. For more information, see Section 8.4.1.2.1, ISS SIMCOP Local Power and Clock Management . |

8.4.1.3.1.2 ISS SIMCOP Module Global Initialization

This procedure initializes the ISS SIMCOP module after a power on or software reset.

Table 8-1239. ISS SIMCOP Global Initialization

| Step | Register/Bit Field/Programming Model | Value |
|------------------------------------------------------|------------------------------------------------------------|-------|
| Execute software reset. | SIMCOP_HL_SYSCONFIG [0] SOFTRESET | 0x1 |
| Wait until reset completed? | SIMCOP_HL_SYSCONFIG [0] SOFTRESET | 0x0 |
| Configure STANDBYMODE. | SIMCOP_HL_SYSCONFIG [5:4] STANDBYMODE | 0x2 |
| Configure submodules interface and functional clock. | SIMCOP_CLKCTRL [7:0] | xxx |
| Interrupt configuration | | |
| Set interrupt enable bit for the submodules. | SIMCOP_HL_IRQENABLE_SET _i [7:0] | xxx |

8.4.1.3.2 ISS SIMCOP Operational Modes Configuration

8.4.1.3.2.1 Interrupts

To unmask an interrupt for generation of SIMCOP_IRQ_i output interrupts, software must set the corresponding bit of [SIMCOP_HL_IRQENABLE_SET](#)_i (where i = 0 to 3) to 1.

Example 1, SIMCOP_IRQ1 is generated when DCT_IRQ or VLCDJ_BLOCK_IRQ are generated:

- [SIMCOP_HL_IRQENABLE_SET](#)_i[2] DCT_IRQ = 0x1 (where i = 1)
- [SIMCOP_HL_IRQENABLE_SET](#)_i[3] VLCDJ_BLOCK_IRQ = 0x1 (where i = 1)
- [SIMCOP_CTRL](#)[1] IRQ1_MODE = 0x0

Example 2, SIMCOP_IRQ3 is generated when IMX_A_IRQ and LDC_BLOCK_IRQ are generated:

- [SIMCOP_HL_IRQENABLE_SET](#)_i[5] IMX_A_IRQ = 0x1 (where i = 3)
- [SIMCOP_HL_IRQENABLE_SET](#)_i[9] LDC_BLOCK_IRQ = 0x1 (where i = 3)
- [SIMCOP_CTRL](#)[3] IRQ3_MODE = 0x1

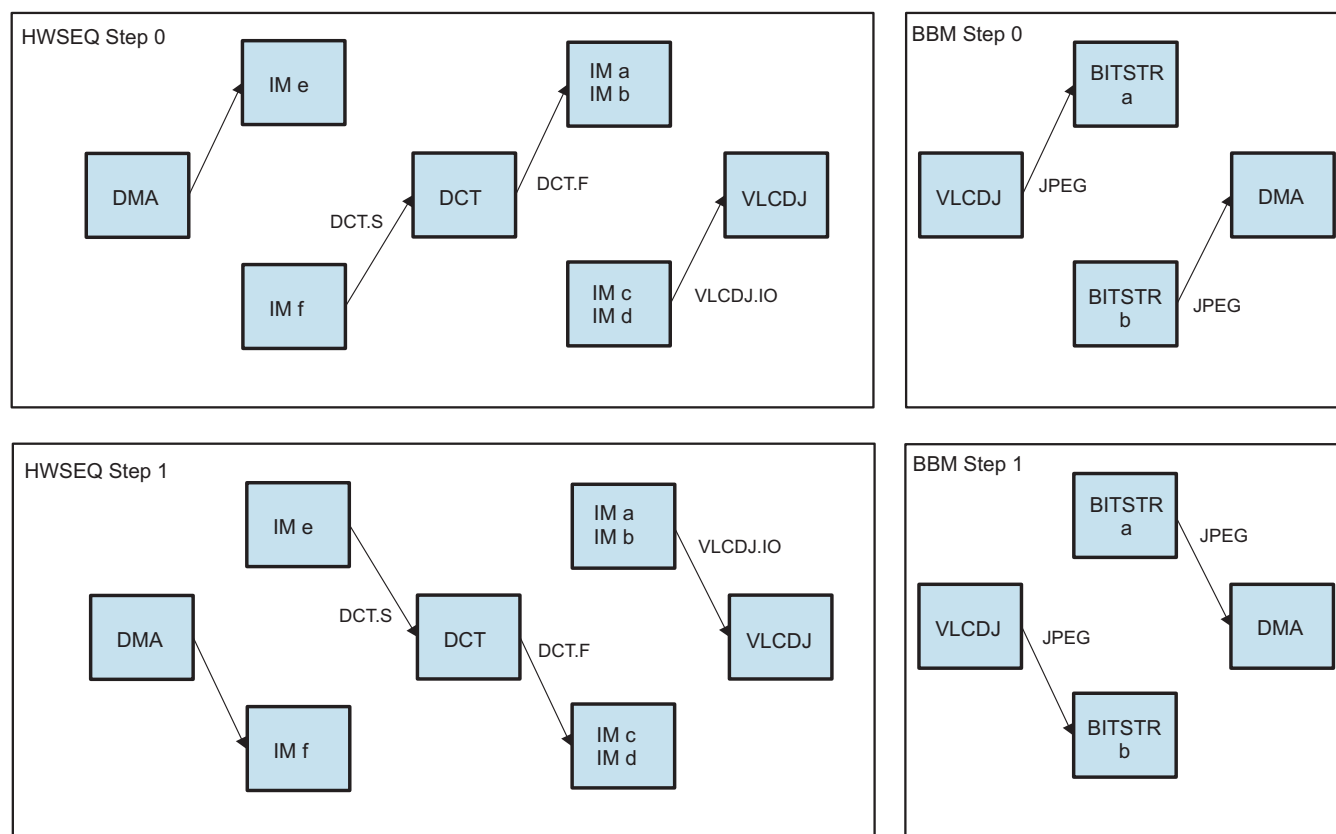

To mask an interrupt for generation of SIMCOP_IRQ_i output interrupts, software must clear the corresponding bit of [SIMCOP_HL_IRQENABLE_CLEAR](#)_i (where i = 0 to 3) to 0.

When an event occurs, the corresponding bit in the [SIMCOP_HL_IRQSTATUS_RAW_i](#) (where $i = 0$ to 3) register is set regardless if the event has been enabled or not. Bits in the [SIMCOP_HL_IRQSTATUS_i](#) (where $i = 0$ to 3) registers are only set when an enabled event occurs. Software can clear a pending event by setting the adequate bit in the [SIMCOP_HL_IRQSTATUS_i](#) (where $i = 0$ to 3) register.

8.4.1.3.2.2 JPEG Encode Operational Mode Configuration

Figure 8-242 shows a typical JPEG encode macroblock pipeline.

Figure 8-242. JPEG Encode Pipeline

simcop-012

Table 8-1240. JPEG Encode Pipeline

| Step | Register/Bit Field/Programming Model | Value |
|-----------------------------------------------------------------------------------------|-------------------------------------------------------------|-------|
| Set SIMCOP DMA to fetch data from SDRAM and stored into an image buffer (IM e or IM f). | See DMA programming model Section 8.4.3.4 | xxx |
| Set DCT to reads data from an image buffer (IM e or IM f). | DCT_SPTR[12:5] ADDR | xxx |
| Set DCT to store data into sets of two image buffers (IM a + IM b or IM c + IM d). | DCT_FPTR[12:4] ADDR | xxx |
| Set VLCDJ to read data from image buffers. | See VLCDJ programming model Section 8.4.6.4 | xxx |
| Set VLCDJ to write the data to the bitstream buffer. | See VLCDJ programming model Section 8.4.6.4 | xxx |
| Set the SIMCOP DMA to send the data to SDRAM. | See DMA programming model Section 8.4.3.4 | xxx |

8.4.1.4 ISS SIMCOP Register Manual

8.4.1.4.1 SIMCOP Instance Summary

Table 8-1241 is the SIMCOP top level instance summary.

Table 8-1241. SIMCOP Instance Summary

| Module Name | Base Address L3 Interconnect | Base Address Cortex-M3 Private Access | Size |
|----------------|---------------------------------|------------------------------------------|-----------|
| SIMCOP_CONTROL | 0x5202 0000 | 0x5506 0000 | 256 bytes |

NOTE: Private Access is an access that does not use the L3/L4 interconnects.

8.4.1.4.2 SIMCOP Registers

8.4.1.4.2.1 SIMCOP Register Summary

Table 8-1242 is the SIMCOP_CONTROL register mapping summary.

Table 8-1242. SIMCOP_CONTROL Register Mapping Summary

| Register Name | Type | Register Width (Bits) | Address Offset | Physical Address L3 Interconnect | Physical Address Cortex-M3 Private Access |
|----------------------------------------------------------|------|-----------------------------|-----------------------------|-------------------------------------|-------------------------------------------------|
| SIMCOP_HL_REVISION | R | 32 | 0x0000 0000 | 0x5202 0000 | 0x5506 0000 |

| Bits | Field Name | Description | Type | Reset |
|-------|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|---------|
| 31:13 | RESERVED | Read returns 0. | R | 0x00000 |
| 12:10 | LDCR_RESP_FIFO | Defines the size of the LDC read master response FIFO in words of 128-bits. Read 0x2: 8x128 bits Read 0x3: 16x128 bits Read 0x4: 32x128 bits Read 0x5: 64x128 bits Read 0x6: 128x128 bits Read 0x7: 256x256 bits | R | 0x4 |
| 9:8 | IMAGE_BUFFERS | This parameter defines the image buffer count. Read 0x0: 4 Image buffers (e, f, g, h) Read 0x1: 8 Image buffers | R | 0x1 |
| 7 | RESERVED | Read returns 0. | R | 0 |
| 6 | ROT_A_ENABLE | The ROT a is present when this parameter is set. Read 0x0: Disabled at design time Read 0x1: Enabled at design time | R | 1 |
| 5 | IMX_B_ENABLE | The iMX B module and the CMD b, COEFF b memories are present when this parameter is set. Read 0x0: Disabled at design time Read 0x1: Enabled at design time | R | 1 |

| Bits | Field Name | Description | Type | Reset |
|------|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 4 | IMX_A_ENABLE | The iMX A module and the CMD a, COEFF a memories are present when this parameter is set. Read 0x0: Disabled at design time Read 0x1: Enabled at design time | R | 1 |
| 3 | NSF_ENABLE | The NSF2 is present when this parameter is set. Read 0x0: Disabled at design time Read 0x1: Enabled at design time | R | 1 |
| 2 | VLCDJ_ENABLE | The VLCD module and the QUANT, HUFFMAN, BITSTREAM memories are present when this parameter is set. Read 0x0: Disabled at design time Read 0x1: Enabled at design time | R | 1 |
| 1 | DCT_ENABLE | The DCT module is present when this parameter is set. Read 0x0: Disabled at design time Read 0x1: Enabled at design time | R | 1 |
| 0 | LDC_ENABLE | The LDC module and the LDC LUT are present when this parameter is set. Read 0x0: Disabled at design time Read 0x1: Enabled at design time | R | 1 |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-------|
| 31:20 | RESERVED | Read returns 0. | R | 0x000 |
| 19 | CPU_PROC_START_IRQ | Event triggered by the hardware sequencer to instruct the CPU to process a macroblock Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 18 | SIMCOP_DMA_IRQ1 | Event triggered by the SIMCOP DMA. This event is automatically cleared at SIMCOP level when it is cleared at SIMCOP DMA level. Check SIMCOP DMA IRQ registers. Read 0x0: No event pending Read 0x1: Event pending | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------------|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------------|
| 17 | LDC2BRIDGE_ERR_IRQ | The LDC2 bridge has generated an error. Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 16 | ICNT_ERR_IRQ | An error has been received on the SIMCOP master port. Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 15 | VLCDJ_DECODE_ERR_IRQ | A decode error has been signaled by the VLCDJ module Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 14 | DONE_IRQ | Event triggered when the hardware sequencer finishes the sequence: - the sequence step counter has reached the limit - all accelerator and DMA events for the last sequence step have been received. Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 13 | STEP3_IRQ | Event triggered when Step 3 is activated by the hardware sequencer Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 12 | STEP2_IRQ | Event triggered when Step 2 is activated by the hardware sequencer Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 11 | STEP1_IRQ | Event triggered when Step 1 is activated by the hardware sequencer Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 10 | STEP0_IRQ | Event triggered when Step 0 is activated by the hardware sequencer Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-------|
| 9 | LDC_BLOCK_IRQ | This event is triggered by LDC when a macroblock has been processed Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 8 | RESERVED | Read returns 0. | R | 0 |
| 7 | ROT_A | Event triggered by the ROT a engine Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 6 | IMX_B_IRQ | Event triggered when iMX has executed a SLEEP instruction. Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 5 | IMX_A_IRQ | Event triggered when iMX has executed a SLEEP instruction. Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 4 | NSF_IRQ_IRQ | Event triggered by the NSF2 imaging accelerator when processing of a block is done. Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 3 | VLCDJ_BLOC_IRQ | This event is triggered by VLCDJ when a macroblock has been processed (encode/decode) Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 2 | DCT_IRQ | Event triggered when a block has been processed by the DCT module and the filter outcome has been stored to an image buffer. Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |
| 1 | LDC_FRAME_IRQ | This event is triggered by LDC when a full frame has been processed Write 0x0: No action Read 0x0: No event pending Read 0x1: Event pending Write 0x1: Set event (debug) | RW W1toSet | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------|-------|
| 0 | SIMCOP_DMA_IRQ0 | Event triggered by the SIMCOP DMA. This event is automatically cleared at SIMCOP level when it is cleared at SIMCOP DMA level. Check SIMCOP DMA IRQ registers. Read 0x0: No event pending Read 0x1: Event pending | R | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-------|
| 31:20 | RESERVED | Read returns 0. | R | 0x000 |
| 19 | CPU_PROC_START_IRQ | Event triggered by the hardware sequencer to instruct the CPU to process a macroblock Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 18 | SIMCOP_DMA_IRQ1 | Event triggered by the SIMCOP DMA. Check SIMCOP DMA IRQ registers. Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 17 | LDC2BRIDGE_ERR_IRQ | The LDC2 bridge has generated an error. Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 16 | ICNT_ERR_IRQ | An error has been received on the SIMCOP master port. Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |

| Bits | Field Name | Description | Type | Reset |
|-------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|--------------|
| 15 | VLCDJ_DECODE_ERR_IRQ | A decode error has been signaled by the VLCDJ module Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 14 | DONE_IRQ | Event triggered when the hardware sequencer finishes the sequence: The sequence step counter has reached the limit. All accelerator and DMA events for the last sequence step have been received. Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 13 | STEP3_IRQ | Event triggered when Step 3 is activated by the hardware sequencer Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 12 | STEP2_IRQ | Event triggered when Step 2 is activated by the hardware sequencer Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 11 | STEP1_IRQ | Event triggered when Step 1 is activated by the hardware sequencer Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 10 | STEP0_IRQ | Event triggered when Step 0 is activated by the hardware sequencer Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 9 | LDC_BLOCK_IRQ | This event is triggered by LDC when a macroblock has been processed Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 8 | RESERVED | Read returns 0. | R | 0 |
| 7 | ROT_A | Event triggered by the ROT a engine Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |

| Bits | Field Name | Description | Type | Reset |
|------|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------|-------|
| 6 | IMX_B_IRQ | Event triggered when iMX has executed a SLEEP instruction. Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
| 5 | IMX_A_IRQ | Event triggered when iMX has executed a SLEEP instruction. Write 0x0: No action Read 0x0: Interrupt disabled (masked) Read 0x1: Interrupt enabled Write 0x1: Enable interrupt | RW W1toSet | 0 |
